

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. TO
THOMAS HAMILTON, M.A., D.D., LL.D.,
President of Queen's College, Belfast,

IN RECOGNITION OF HIS UNTIRING EFFORTS FOR
THE ADVANCEMENT OF

Medical Education and Scientific Research

THIS VOLUME IS GRATEFULLY DEDICATED
BY THE AUTHOR.

70542

PREFACE TO FOURTH EDITION.

AFTER having been out of print for more than two years the work has been thoroughly revised and brought up to date, much of it having been re-written. Though a considerable amount of the text of former editions has been omitted, the amount of new material added has been so great that the bulk of the volume has increased by about 60 pages, notwithstanding every effort to keep it in its old limits of 1,000 pages.

The numerous prescriptions scattered throughout the volume have been but slightly altered, but new ones have been occasionally added.

To bring the Surgical articles up to date the author has availed himself of the aid of A. B. Mitchell, F.R.C.S.I., Surgeon to the Royal Victoria Hospital, who has revised this portion of the work, and the more important of his additions are marked by his initials. He has re-written the article upon Wounds, and thoroughly revised the operative treatment of Gastric Ulcer and Cancer, in which department of surgery he has already achieved marked success.

To Dr. Cecil Shaw the author is indebted for a careful revision of the articles on Diseases of the Eye and Ear. He also gladly acknowledges the valuable assistance of Dr. Victor Fielden in the correction of the proof sheets and the preparation of the Index.

Since the last issue in England, the work has passed through two Editions, printed at Hangchow in the Chinese language.

He is deeply grateful for the innumerable expressions of thanks which he continues to receive from his medical brethren who have found the volume helpful to them in their arduous professional life-work, and he sincerely hopes that the present edition will be found to contain a full and complete epitome of Twentieth Century practical therapeutics.

COLLEGE SQUARE N., BELFAST,
November, 1901.

PREFACE TO FIRST EDITION.

THE issue of each edition of the writer's work on Pharmacy, Materia Medica, and Therapeutics, brought suggestions from many members of the profession, both teachers and practitioners, upon the necessity of appending to it a Therapeutic Index, or Index of Diseases, for reference. With the view of acting upon these suggestions, and of furnishing the practitioner and student with a complete list of drugs suitable for the treatment of the various diseases, a Therapeutic Index, such as forms a portion of nearly every modern work on Materia Medica, was commenced. It soon, however, became evident that the practitioner or student would be assisted but little by a mere enumeration of the drugs suitable to the treatment of each affection, unless the list was accompanied by some expression of opinion regarding the relative value of each drug, and of the different methods by which it might be employed.

What was at first undertaken with the intention of being compressed into 50 or 60 pages, has gradually grown into a volume of nearly 1,000 pages, and the greatest difficulty was experienced at every point in keeping it within its present limits. The necessary condensation prohibited the discussion of pharmacological questions, and necessitated the briefest reference to authorities, the writer having to remain content with giving the results of his own practical experience in the briefest manner possible, before mentioning the various methods of treatment pursued successfully by others.

Surgical questions are treated for the most part briefly, but the writer has frequently expressed his own opinions, formed during several years of practice, when surgical methods formed the major part of his daily work, in conjunction with the late Professor Gordon.

ABDOMEN, DISEASES OF.

See under their special headings, as Ascites, Aneurism, Tumour, Peritonitis, Liver, Kidney, Ovary, Uterus, &c., &c.

ABORTION.

Remedial agents may be demanded in the early months of pregnancy at any of the following three stages:—

(1.) If there be a history of recurrent abortions, it will be necessary to take measures to prevent the expulsion of the non-viable foetus, and tide over the dangerous period, though no threatening symptoms may be present.

(2.) If symptoms of threatening abortion have already appeared.

(3.) If the process of expulsion has already made a fair start, and there is no prospect of saving the foetus.

1. The common conditions which predispose to abortion are syphilis, Bright's disease, valvular affections, previous endometritis and unhealthy states of the lining membrane of the uterus, tumours, and mal-positions of the organ.

If there be any reason to suspect syphilitic taint, a mild mercurial treatment should be commenced early and continued with circumspection and with intermissions till after the sixth month. Salvation should never be produced, and it is comparatively easy to keep the patient under the influence of the drug without in any way depressing the system or affecting the general health. $\frac{1}{4}$ gr. of Perchloride of Mercury three times daily in simple solution, or $\frac{1}{4}$ gr. of Grey Powder in pill, morning and night, may be continued for a long time. Should distinct evidences of recent syphilis be present, active treatment with much larger doses must be commenced without loss of time.

The way in which the patient bears mercury in doubtful cases may be taken as evidence for or against a syphilitic taint. (See under Syphilis.)

Where the syphilis has been of long standing, and mercurial treatment has been at one time properly pushed, Iodide of Sodium in large doses, say 10 grs. three times a day, may be given with advantage, and especially if there be any kidney mischief. Iodides are also valuable in those cases where no history of syphilis can be obtained, and in those cases of so-called fatty degeneration of the placenta 5 grs. three times a day, in pill, may be given for several weeks. In this latter class Chlorate of Potassium in moderate doses is of decided value. It should not, however, be given in renal cases.

Heart affections, when present, must receive most careful attention, and signs of failing compensation should be met by moderate doses of Digitalis and prolonged rest. Renal diseases will call for mild salines and diaphoretics.

Abortion having occurred once, it is liable to be repeated the expulsion of the fœtus often occurring about the same time in each subsequent pregnancy. In these as in the former class of cases, everything that might in any way cause excitement of the genital apparatus must be guarded against, and the dangerous period watched with care, and the patient kept in a state of absolute rest in bed at this time, and also at the time in which the ordinary menstrual flow might be expected to appear had she not become pregnant. After correcting flexions or versions, if present, the physician may keep the patient who has acquired the habit of aborting upon 3 gr doses of Extract of Viburnum in the form of a pill, three times a day, or minute doses of Mercury, or moderate doses of Iodide of Potassium or Chlorate of Potassium, until the dreaded period has passed. Some authorities recommend small doses of Ergot under these circumstances, but the practice is not without risk.

Asafetida enjoys a high reputation in Italy as a prophylactic in recurrent abortion. The Venetian method is to administer a pill containing 14 gr. of the gum-resin twice a day as soon as there is evidence of pregnancy; this dose is gradually increased till 10 pills are daily taken (15 grs.), and towards the later months the drug is given in gradually decreasing doses.

2. Where abortion already threatens, as evidenced by slight hæmorrhage or some pains, an attempt should always be made to prevent it. Absolute rest, by keeping the patient flat upon a firm bed with light covering, is essential. Opium or Morphia is the main drug to be relied upon, and may be given freely—1 gr. of the Extract of Opium every 3, 4, or 6 hours as indicated. The drug can often be given with great advantage by the bowel as a suppository. 3 to 5 grs. of Acetate of Lead have been used by some, and 10 minn doses of Tincture of Digitalis, but their value is doubtful except when given in combination with Opium. Where Opium fails Morphia, combined with Digitalis, may succeed. The writer has seen uterine hæmorrhage stopped by this combination after the failure of all other remedies. Viburnum Prunifolium or Black Haw is in great repute in America, and may be given in doses of 1 to 3 drs. of the fluid extract, or it may be given in the pilular form.

Savin, Ergot, and other Echolics, which are said to act as uterine sedatives when given in small doses, are not to be relied upon. Hydrastis in 20 minn doses of the tincture is a valuable hæmostatic, and may be tried alone or with Opium. Laxatives should be employed to prevent constipation; Castor Oil is the best, but enemata should not be used.

Too much trust must not be placed in internal remedies, and

internal medication should cease as soon as there is any evidence that the death of the foetus is probable. The danger of paralysing the uterus by means of large doses of sedatives whilst a dead foetus is contained in it, and the subsequent risk of septicæmia, should be ever before the physician.

3. When it is evident that abortion cannot be prevented, and that the foetus is still out of reach, and that there is no hope of a speedy spontaneous expulsion, the proper course to pursue is to give *liqor*, 30 minims of the Liquid Extract, every 3 or 4 hours, and plug the vagina with iodoform gauze or cotton wool through a Sims speculum, after the free use of a 1 in 2,000 Sublimatè Solution to the external genitals and to the vagina. Spiegelberg inserted by forceps pledgets of cotton wool with the right hand, keeping two fingers of the left hand held wide apart in the vagina, the plugs are inserted without any attached strings, each is greased with Carbolic Oil (1 in 5) and thrust well up against the os until the vagina is thoroughly packed. When possible the gauze or carbolic wool may be introduced inside the os. The writer dusts freely Boric Acid over the pledgets, and packs the spaces between them with this substance. The advantage of this is that the plug may not be removed for 24 hours, when the foetus and membranes almost always are found along with it. The most convenient method of plugging the vagina is to introduce strips of iodoform gauze, 4 inches wide and 3 yards long, through the speculum when the patient is in the semi-prone position, a large firm ball of the gauze being pushed up into the posterior fornix at the beginning. If by the end of two or three days the contents of the uterus are not expelled or within reach of the finger they should be removed, especially if hæmorrhage to any extent be present. If this can be done by the sterilized finger thrust into the uterus no instrument should be employed, but sometimes the curette will be needed to remove all adherent portions of the membranes, after which the interior of the uterus should be swabbed with a strong Carbolic Solution, or with the pure Acid, or with a Solution of Corrosive Sublimatè (1 in 4,000). Where the os fails to dilate, Hegar's dilators, or tents, must be employed.

The routine practice of at once introducing the curette upon the first signs of hæmorrhage, and of scraping the interior of the uterus and washing with Sublimatè Solution, is not to be recommended. If symptoms of septic poisoning or of decomposition of the uterine contents set in, evacuation should be performed as soon as possible, the curette freely used, and the uterine cavity sterilized with pure Carbolic Acid; antiseptic lotions or injections must be frequently employed afterwards till the danger is passed. Where the hæmorrhage is copious and persistent, when the patient first comes under observation, all plugging may be omitted and rapid digital or other dilatation attempted, and as soon as the finger finds entrance into the uterus the contents may

be hooked down and the cavity cleared out, the removal being greatly facilitated by the pressure of the operator's left hand upon the abdominal walls.

Where the finger cannot reach the fundus it may be made to do so by retroverting the uterus through pressing the fundus towards the sacrum. Often when a catheter can be got through the os a stream of hot water may be injected. This may produce vigorous contractions which will expel the ovum, or the finger may be slipped through after the relaxation which afterwards follows. When the curette is used, which should be seldom, a blunt one should be selected. Instruments for the extraction of the fetus or its membranes are not to be preferred to the finger.

Where hemorrhage follows the expulsion of the fetus and its membranes it is likely that some portion of the placenta is retained, and this should be removed by dilatation and the finger or curette, and a free stream of antiseptic liquid.

After the expulsion or extraction of the fetus the after-treatment should consist in the daily use of a vaginal antiseptic solution (1 per cent. Creolin), rest in bed, milk diet, and the usual routine management indicated in the after-treatment of ordinary labour. As a rule, six or seven days' rest in bed will suffice for most cases in the absence of septic complications. Involution is not hastened by prolonged rest.

Tubal abortion when recognised by its history of small hæmorrhages, followed by pain and tenderness over a swollen tube, and possibly by the expulsion of shreds of placental tissue, should be met by prompt surgical measures with the view of anticipating the fatal rupture of the sac, abdominal section and thorough drainage being indicated.

ABSCESS.

Though little success may be expected from agents used to prevent suppuration, nevertheless, when formation of pus threatens, constitutional or internal treatment may be tried to cause diminution or abortion of the suppurative process. Saline purges, large doses of Quinine, 10 minim doses of Tincture of Belladonna, natural Sulphur waters, or $\frac{1}{16}$ gr. of Sulphide of Calcium in pill, may be given every three or four hours. The results are, however, generally disappointing. Locally, the suppurative stage may be cut short by *absolute rest*, the application of alcoholic extract of Belladonna, 1 drachm, and Glycerin, 1 drachm, smeared over the part. Poultices, by dilating the capillaries and small blood-vessels, relieve tension, and may effectually prevent suppuration. Cold applications, by causing a diminution in the size of the small vessels, may check the process by cutting short the increased supply of blood. Elevation of the part sometimes secures the same result. By covering over the surface of a poultice with extract of Belladonna, and keeping the patient in a horizontal position, threaten-

ing mammary abscess may be often prevented. Pain is relieved by these means if suppuration supervenes. Local blood-letting often gives relief, and may check suppuration.

In acute cases, if suppuration has already taken place, there should be no attempt at waiting for the abscess to point. Whilst making its way to the surface, the pus is also spreading in other directions. Delay involves destruction of healthy tissues. The sooner an acute abscess is opened the better. The surrounding skin should be rendered as aseptic as possible, a free incision made into the abscess cavity, and provision made for efficient drainage. By freezing the part with Ether spray or Ethyl Chloride the pain of the incision may be prevented. Injection of a few minims of 3-5 per cent. solution of Eucaine or Cocaine into the substance of the skin, along the line of incision will render the little operation quite painless. The author finds that by smearing the part lightly over with the cork or stopper of the carbolic acid bottle, a sufficient amount of local anesthesia is obtained, and a certain degree of antiseptic effect is, at the same time, produced. The incision should be deep and free, and so made as to cause the least scar and the best drainage. Where a small incision is desirable, the use of the aspirator is to be condemned; in such a case a fine drainage tube, thoroughly disinfected, may be inserted through an incision not much larger than the diameter of the tube. The part may be dressed with simple boiled gauze covered with absorbent wool or wood wool, or any of the specially prepared antiseptic gauzes may be employed, most surgeons now preferring the use of dry dressing. By those who still hold to the old and very convenient plan of moist applications any of the following lotions may be applied upon lint and covered with oiled silk. The quantities will make 40 oz. of lotion:—

Carbolic Acid, 1 oz.; or Methylated Spirit, 10 oz.; or Chloride of Zinc, $\frac{1}{2}$ oz.; or Corrosive Sublimate, 5 grs.; or Permanganate of Potash, 20 grs.; or Boracic Acid, 2 oz.; or Boroglyceride, 3 oz.; or Tincture of Iodine, 6 drs., and distilled water to 40 oz.

If any tetor exists, the cavity of the abscess may be freely washed out with the above solutions, and if unusually extensive, 50 per cent. of water may be added. For small suppurating cysts and abscesses in connection with diseased bone, solutions of double the above strengths may be used, or the cavity may be swabbed with lint soaked in solution of Chloride of Zinc, 1 in 10, Carbolic Acid, or Iodized Phenol (Iodine, 1 oz.; Carbolic Acid, 4 oz.), and afterwards washed out thoroughly with any of the above solutions.

Where there is considerable pain and tension a pad of salicylic, boracic, or iodoform wool, soaked in hot water and covered with oiled silk, may be applied. Abscesses in the neighbourhood of sources of putrefaction, as about the anus, should be opened at some distance from the dangerous region, even though it should not be the most dependent spot. An incision should be made

through the healthy skin a few inches distant, and a canal tunnelled to the sac of the abscess.

In opening deep abscesses, especially in the region of large and important vessels, as in the neck and axilla, Hilton's method should be employed—An incision being made through the skin by a scalpel, the blades of a pair of dressing forceps are inserted deeply and then opened forcibly, so as to tear through the deeper tissues until pus is reached, after which a drainage tube is inserted, and the wound dressed as before described.

For abscesses of ordinary size the writer has found the best routine treatment to be a large pad of well-teased carbolic tow laid over the wound and secured by a slick bandage, and in cases where expense is to be considered, a similar pad of oakum will be found a splendid dressing. One dressing in 24 hours, even in profuse suppuration, will generally be sufficient, as the pad can be made sufficiently large to soak up a large quantity of pus. A few shreds of the tow or oakum may be pushed into the cavity and left projecting from the wound. In this way all the advantages of a drainage tube may be obtained, and the lips of the incision are at the same time prevented from healing, and the sac allowed to granulate from the bottom. Where the abscess continues to discharge the Compound Tincture of Benzoin has been injected by the writer with great success. It often causes rapid healing and is a powerful antiseptic, and produces little irritation or pain.

To treat acute and chronic abscesses by the strictly aseptic plan the skin of the patient, hands of the surgeon, and all instruments and dressing are thoroughly sterilised (See Wounds). After pressing out the contents of the sac its walls may be well scraped with a sharp spoon and a boiled drainage tube inserted; the wound is then squeezed as dry as possible, and covered with several layers of sterilised gauze and absorbent wool, and carefully bandaged. Each change of the dressing should be carried out under strictest antiseptic precautions.

Though in almost every case organisms already exist in the contents of the cavity, nevertheless antiseptic precautions and relief of tension, with the evacuation of the pus, are sufficient to ensure rapid healing, and if free drainage be ensured no putrefaction should ever follow.

Chronic abscess must be regarded as differing very widely from the acute form in its pathology and in the indications for treatment. Here the signs of inflammation are slight or absent, the staphylococci, so characteristic of acute suppuration, are also absent. The chronic abscess is, in the great majority of instances, simply a softening tubercular deposit. Nothing could be more disastrous than the plan, so frequently followed by the general practitioner, of making an incision into such an abscess, and after evacuation of the fluid contents inserting a drainage tube or applying a poultice. The inevitable result of such a line of treatment is to set up an acute suppurative process in the lowly

vitalised tubercular tissue forming the abscess wall, followed, especially if the abscess be a large one, by a low form of septic fever which may persist indefinitely.

From the outset a chronic abscess should be regarded as a serious condition for which thorough and radical treatment is essential. The surgeon's aim should be to remove not only the fluid contents, but also every trace of tubercular tissue. With this object in view, an anæsthetic should if possible be administered, and some of the following methods carried out under strict aseptic precautions:—

(1). Complete excision is the best method where the abscess is small and subcutaneous, the abscess wall and contents being removed like a sebaceous cyst.

(2). Where the abscess is large and a scar is not a matter of importance, *e.g.* on the limbs and trunk, the abscess should be laid freely open from end to end, and every trace of lining membrane scraped or dissected away. The cavity left should be carefully dried, the wound closed without drainage, dressed with sterilised gauze, and firmly bandaged. Generally the dressings do not require removal for a week if the operation has been thoroughly aseptic.

(3). For large deep-seated abscesses, *e.g.*, Psoas, or where the mark is of importance a short incision may be made and the abscess cavity thoroughly scraped out with Barker's flushing curette, then dried with strips of gauze packed in tightly and withdrawn, and finally closed without drainage. Should the abscess reform, it should be again scraped and closed.

Bilroth, Barker, and others, after scraping out the tubercular tissue fill the cavity with Iodoform Emulsion before suturing.

Wile for acute or chronic abscesses, inserts a large-sized aspirator needle into the sac, and to this he attaches a special little pump, and removes all of the contents possible. The sac is then filled quite full (moderately distended) with equal parts of water and a 20 per cent solution of Peroxide of Hydrogen through the needle without removing it. Immediately the cavity becomes distended, and the accumulated gas and solution rush through the needle, carrying much debris with them. The pump is again applied, and everything removable pumped out. More solution is then injected and removed till a perfectly clean cavity is obtained. A solution of Corrosive Sublimat (1 in 2,500) is then injected and withdrawn two or three times till a perfectly aseptic cavity is obtained. The needle is then removed, and over the site of the abscess a large pad of iodoform gauze is fastened by a perchloride of mercury gauze bandage, which is left *in situ* for from four to ten days, after which time he reports that he always finds complete closure of the cavity, perfect adhesion of its walls, and not a trace of the abscess left.

Bruns treats all tuberculous and joint abscesses in a similar manner. He aspirates thoroughly by inserting a needle into the

sac or joint, and injects a sterilised 10 per cent. emulsion of iodoform in glycerin or olive oil. Into large joints he injects 2 to 6 c.c. at one or various points. All cold abscesses, spinal abscesses, and every joint abscess, as well as tubercular empyema, may be treated in this way, and Trendelenberg applies this plan to the treatment of all forms of local tuberculosis of soft parts, as of glands, testes, and lungs. The process requires repetition about every 10 or 14 days.

Verneuil treats all chronic or cold abscesses by aspiration and the injection of antiseptic solutions as just mentioned, his favourite agent being iodoform dissolved in ether.

ACIDITY.

The regurgitation of acid liquid from the stomach in dyspepsia and other gastric affections is but a symptom of these affections, and its treatment should only be discussed as part of their therapeutics. It is, however, briefly referred to here for convenience and facility of reference.

It has been assumed that the very painful acidity coming on after a meal during a period of gastric digestion is caused by an increase in the amount of gastric juice secreted. The burning liquid which sets the teeth on edge and feels like vitriol as it regurgitates into the mouth is a mixture of butyric and lactic acids, often with some acetic. It is the product of decomposition, arising from fermentation in the sugar, starch, or fats swallowed, and, in most instances, it arises from delayed digestion caused by a deficient supply of gastric juice. It is, consequently, intensified by those remedies which diminish the amount of the digestive fluid.

The physician is often called upon, in an acute attack, to relieve the severe pain produced by the irritation of the acid. To give acids under such circumstances is worse than useless. One large dose of an alkali gives immediate relief. The amount should be sufficient to neutralise the large and often enormous quantity of highly irritating acid present. Fermentation is at once arrested—2 drs. or more of Bicarbonate of Soda or Potash may be required and their efficacy will be increased if administered in effervescent potash or soda water. If this should fail to give relief, an emetic must be administered.

Alkalies are not to be *habitually* employed, or serious troubles may result, but when indicated they may be given unsparingly for short periods. Often at the beginning of what would become a painful attack, one large dose of Lactopeptin, 30-45 grs., will dispel all uneasy sensation, and there is no objection to such treatment being frequently employed. Pepsin is more valuable, as it may be given with full doses of alkalies, whilst Pepsin will only digest with acids. In very chronic cases, and especially where the fermentation is dependent upon some organic lesion, such as obstruction at the pylorus, all treatment fails,

because the stomach still retains some ferment when the fresh food is swallowed, and thus the process is kept incessantly going on. In such cases, very satisfactory results may be obtained by washing out the stomach thoroughly with a weak solution of Creosote or Condy's Fluid. The writer has seen pain and acid vomiting disappear, never to return, after having withstood everything prior to this treatment. Having relieved urgent symptoms, remedies may be commenced which retard or prevent fermentation changes, and foremost amongst these is Creosote, in two minim capsules, of which 3 or 4 may be given during the day—i.e., one about an hour after each meal.

Carbolic acid, 1 to 3 minims, may be likewise used. Sulphurous Acid, in doses of 1 dr., freely diluted; Sulphocarbonates of Soda and Potash, Sulphites of the same bases, or Salicylates, in 10 to 20 grain doses, may be given, or Oxide or Nitrate of Silver in doses of $\frac{1}{2}$ grain in pill. Often the writer has obtained benefit from 5 minim doses of Oil of Peppermint, which is a powerful and harmless antiseptic.

Charcoal freshly dried and given in the dry state, wrapped up in water paper, is a powerful absorbent of the gas which accumulates during the acid fermentation, and which adds to the distress of the patient.

Having relieved the more acute stages, the physician should direct attention to the condition of the gastric mucous membrane, which is the source of the trouble. An excellent combination is

R. *Bismuth. Carb.* gr. x.
 Magnes. Carb. Pond. gr. xxx.
 Papain, (Finkler) gr. ii.
 Morph. Hydrochlor. gr. $\frac{1}{12}$ misc.

Fiat pulv. tales xxiv. Sumat unum ter in die post cibos.

These may be given soon after or midway between meals. It is a great mistake in these cases to give opiates in such doses as might affect the cerebrum. $\frac{1}{2}$ gr. Opium will be found a maximum dose for the purpose, i.e., to act as a local sedative. Often $\frac{1}{4}$ gr. will be found sufficient. After a time, Tonic—the vegetable bitters in combination with Mineral Acids—may be judiciously administered.

It is of the utmost importance to regulate the diet, and everything found by the patient to increase the acidity should be carefully avoided. Pastry and fermented liquors are especially hurtful. English beer should be forbidden, though Pilsner and Lager beer may be freely taken. Wines of all kinds should be used with great caution. Starchy and saccharine foods should be given with care, but meat, fish, and poultry may be allowed. Skimmed milk and kah water or lime water may constitute the entire diet until the stomach returns to its normal condition.

Sir W. Roberts maintained that the source of the acid in *acid dyspepsia* is exclusively due to over-secretion and not to fermentation. The writer believes this to be at variance with his experience in all *severe* cases, which he often finds to be caused by the use of *baked* fat meats or twice cooked hashes or stews.

Yeo rightly insists upon the importance of prescribing a diet rich in animal albuminates and poor in starches and fats.

The best diet in hyperchlorhydria or hydrochloric hyperacidity is still to be determined. Hemmeter points out that the disadvantage of proteids (especially meats) lies in the fact that though they neutralise more of the hydrochloric acid, they ultimately increase its secretion. He advises boiled and baked starchy food after the excess of acid has been neutralised by the administration of alkalis. Many recent authorities prohibit meats, and feed upon extra-cooked starches. Lean meat is believed to be injurious. Wirschubski insists, from the results of laboratory experiments, upon the necessity of a diet consisting mainly of fats and carbohydrates. Morgan gives large quantities of sugar. Olivette administers through a soft tube 150 grs. Subnitrate of Bismuth every morning. Hewes states that the first step in the treatment of gastric acidity is to administer substances which combine with or neutralise the acid, and such substances are, firstly, proteid foods which combine with large quantities of acid and, secondly, alkalis which neutralize the acids present. This simple method, he states, works out in a large majority of cases satisfactorily. In obstinate cases, where there is reason to suspect hyperplasia of the tubular structures in the stomach, the method of continuous treatment upon low proteid diet should be tried.

ACNE.

Disorders of digestion, sexual excitement, and menstrual disturbance should be corrected by appropriate remedies. The presence of a large amount of sugar in the diet, and the free use of beer, wines, and all fermented liquors are to be forbidden. In those predisposed to acne absolute cleanliness is essential, frequent washing and scrubbing to remove all secretion, to stimulate the glands and to prevent the entrance of infective organisms.

One large dose of Cod Liver Oil at bed-time to act as a laxative, especially in thin subjects, is of great value. The best results, in robust patients, are obtained by frequent purgation by an active mineral water or saline cathartic.

Sulphur and Arsenic internally—10-20 grs. precipitated sulphur mixed with a teaspoonful of orange marmalade, and the dose administered once or twice daily, produces often good results. 10 gr. Sulphide of Calcium, in a pill, acts in a similar manner.

In very chronic cases Arsenic may be tried, but this remedy must be continued for a considerable period before good results

are obtained. The dose need never exceed 4 minims of Fowler's Solution, and should be given 3 times daily along with meals. It is advisable to give arsenic for 5 or 6 weeks, and then stop and begin the internal use of sulphur for 2 or 3 weeks, and continue thus alternating for several months; or, whilst arsenic is being administered, one nightly large dose of sulphur (1 drachm) may be given. Belladonna, Ergot, Ichthyol, Nitrate and Oxide of Silver, Phosphorus, and many other drugs, are recommended. When internal remedies do good it is only because they have probably relieved the affections which are the cause of the disease: they cannot be said to have a specific effect upon the sebaceous glands.

It is to the *local* treatment that attention must therefore be chiefly directed, and nearly every dermatologist has his own plan, but there is no diseased condition in which greater patience and perseverance is demanded in the carrying out of details.

The best local *preventive* treatment consists in the use of antiseptic lotions to secure complete asepsis of the skin, free stimulation of the sebaceous glands by friction and medicated soaps (Eichhoff's Camphor-Sulphur) and steaming of the affected region. The luxuriant origin of the disease maintained by Unna has led to the extensive use of Sublimate solutions.

In the milder forms of the disease, the inflamed glands, with their obstructed ducts, should be submitted to smart friction with a rough towel after thorough washing with soap and hot water, or steaming of the face over boiling water. Any of the pimples or comedones which show black points or evidences of pustulation should be pressed and their contents squeezed out by firm pressure with the fingers; or, better still, by firmly pressing with a watch-key form of instrument devised for the purpose. Good results may sometimes be obtained by mowing down the summits of the comedones with pumice stone, fine sand, or powdered marble before applying pressure. After this the following lotion should be freely dabbed over the face and allowed to dry.—Precipitated Sulphur, 2 drs.; Prepared Calamine, 40 grs.; Spirit, 1 oz. Rose Water 9 oz. The Sulphur, according to some observers, acts better if combined with an alkali, and the following combination may be regarded as an exceedingly dilute Vienneux's Solution:—

R.	Sulphur. Præcip.	℥ij.
	Calamina Præp.	℥ss.
	Aquæ Rosæ	℥v.
	Eau de Cologne	℥ij.
	Aquæ Calcis ad	℥xii. misc.

Fiat lotio, M. d. u. p. p. a.

This will be found the most satisfactory method of dealing with mild cases of acne of the face, when there is moderate suppuration and little pain and redness. If the acne does not soon yield, a lotion consisting of Corrosive Sublimate, 12 grs.; Spirit, 1 oz.; and Almond Emulsion 8 oz., with Glycerin, 1 oz., may be tried. These lotions should be freely applied at least morning and night, and, when possible, once or twice during the day, and allowed to remain on till next application of the soap and friction.

Care should be taken that the Sulphur and Sublimate lotions be not applied at the same time, as discolouration may result.

Ointments may be used with advantage at night, and Calamine lotions in the day time with advantage.

R. Sulphur. Precip. gr. xxx.
Calamina Precip. gr. xxx.
Lanolin. Purif. ʒi.
Acid. Carbolic m. xv. misc.

Fiat Unguentum.

Some cases in the author's hands have yielded to an ointment of Hypochloride of Sulphur, 1 dr., and Lard, 1 oz.

Shoemaker insists upon the puncturing and evacuation of all pustules by incision with a needle-knife instrument in preference to squeezing, and followed afterwards by soothing ointments of Oleates of Lead and Bismuth, 2 drs. to 1 oz.

It is a good plan to apply a small quantity of pure Carbolic Acid to the interior of the pustule after incision and expression, this can be done by inserting a pointed piece of soft wood dipped in the acid.

Where there is much tenderness and redness, with free pustulation, the friction must be dispensed with, and soap used very sparingly. An over-fatted basis soap may, however, be freely used in all cases of acne, and Eichloff's Sulphur-Camphor Soap is of great use where suppuration has occurred. In those cases where active inflammatory changes are going on, an astringent lotion of strong Solution of Subacetate of Lead 4 drs., Spirit, 1½ oz., and Rose Water, 10 oz., may be freely applied after steaming of the face.

Where there is much induration present, steaming and friction should be followed by mild mercurial ointments such as Diluted Citrine Ointment, or Hebra's Solution of Green or Potash Soap in strong spirit, may be rubbed in (Green Soap, 4 oz.; Rectified Spirit, 2 oz.; Spirit of Lavender, 1 drachm). Or a mixture of 4 drs. of Liquor Potassæ, and ʒj oz. Elder Flower Water, may be applied.

Hertzmann's method of treating indurated or pustular acne is to apply strong Perchloride of Iron Solution to each pustule after

evacuating it; to apply frictions to the face of Carbolic lotion, 3-5 per cent., and afterwards 1 dr. Salicylic Acid in 8 oz. strong Alcohol.

For the seborrhoeic form he advises daily frictions of Fleming's Solution (described in the article on Scabies). For the papular form he recommends friction with a weak Hebra's Soap Solution, and in very bad cases the following:—Naphthol, 2½ drs.; Sulph. Præcip., 1½ oz.; Lanolin, 2 oz.; Sapo Viridis, 2 oz.

Ichthiol and Iodide of Sulphur Ointments have been used in very chronic cases with benefit. The injection of Nitric Acid or Perchlorate of Mercury Solution into the pustules is a plan that few will ever try. It produces pain, often of a very severe kind, and may cause unsightly scars, but good results may be produced by touching the summits of the pimples with pure Carbolic Acid, and covering with a layer of collodion, as practised by Walter Smith, only operating upon a limited number at once; the pustules may thus be caused to wither up and disappear without leaving a scar.

The author has had success, after failure with the above list by using the following valuable formula of Unna:—Benzoated Zinc Ointment, 10 drs.; Rice Starch, 5 drs.; Pure Resorcin, 30 grs.; Corrosive Sublimate, 3 grs. This should be well rubbed in after steaming and washing with an over-fatted basis soap 3 or 4 times a day.

Unna also recommends an ointment consisting of Lanoline, Lard Solution of Chloride of Calcium Oxygen Water, 2½ drachms each and Precipitated Sulphur, 1 drachm.

ACNE ROSACEA

In its early stages is almost always dependent upon an irritable condition of the gastric lining membrane, often associated with distinct evidence of dyspepsia, and the physician should vigorously attack this error. If not corrected the erythematous stage will sooner or later pass into one of persistent dermatitis with pustulation, thickening, and hypertrophy, which can only be relieved by the *knife or cautery*. The treatment should be directed to the cause of the dyspepsia, and if this can be discovered to be depending upon the ingestion of irritating food, alcoholic beverages, or condiments, such should be at once stopped; irregularities in the times of eating should be avoided, and of all remedies *alkalies* are most useful. Bismuth Carb., 10 grs.; Magnesia Carb., 10 grs.; Powdered Opium, ½ gr., three times daily midway between meals. Or, Gregory's Powder, 1 oz.; Powdered Gentian, 1 oz.; and Bicarbonate of Soda, 1 oz., mixed and given in doses of a large tea-spoonful in water after meals.

Saline purges following a pill consisting of Blue Pill, 4 grs.; Eucosmin, 2 grs., every third night, are very useful. Abnormal irritability of the gastric nerve endings, leading to vasomotor disturbances in the circulation of the nose and face, is always

present, and the author finds that the following often gives marked relief: Antipyrine, 100 grs.; Liquid Extract of Coca, 2 oz.; Tincture of Orange 1 oz.; Glycerin 1 oz., in doses of a teaspoonful between meals.

A 2 minum Creosote capsule given before meals often removes the dyspeptic troubles, and diminishes the congestion caused by the reflex inhibition of the vaso-motor nerves. In women, acne rosacea sometimes arises in the disturbance caused by the cessation of the menstrual flow, and here attention should be at once directed to the state of the nervous system, and undue reflex excitability combated with full doses of Bromide of Sodium, with 2 minum doses of Fowler's Solution.

Morris finds Ichthyol the most trustworthy internal remedy, often bringing about a marked improvement in a short time. He claims for it that it regulates the bowels, prevents flatulence, helps the digestion, stops the reflex flushing, and steadies the circulation. He gives 5 grs., gradually increased to 10 grs. in capsules, tablets, or pills late at night and in the morning before breakfast. Munro recommends Suprarenal Extract, two 5 gr. tablets daily, increased to six, and at the same time paints one tablet in 1 dr. water over the affected part.

Local medical treatment is of little value. In the early stages some relief may be obtained by Alkaline lotions. Bicarbonate of Soda, 1 oz., in water 30 oz., freely applied; or an ointment of 4 drs. of strong Solution of Subacetate of Lead to 2 oz. of Lanoline may be applied.

Shoemaker advises an ointment of Oleate of Bismuth to be applied and the greased surface powdered over with a mixture of Oleate of Zinc, Carbonate of Bismuth, and powdered Starch.

Petrin incises any pustules, and paints on the following for three days, and claims a cure in three weeks:—Resorcin, 15 grs., Ichthyol, 30 grs.; Collodion, 1 oz.

Abraham recommends local hypodermic injections of 30 minims of 95 per cent Alcohol two or three times a week, he claims for this treatment that after the swelling, caused by the injections, subsides the dilated vessels are obliterated and the disease disappears. Electrolysis has sometimes been resorted to successfully.

Scarification by a needle-knife instrument, containing many small blades drawn across the affected part to cause obliteration of the hypertrophied vessels, or the use of the instruments devised by Vidal and Unna, has been followed by good results. Electrolysis carried out by thrusting a fine needle, connected with the negative wire from about six Leclanche elements, deep into the tortuous vessels is practised. The continuous or Faradic current may be tried, and if there be much hypertrophy free removal must be carried out by the surgeon either with the knife, Paquelin's, or the galvano-cautery. The most radical and only efficacious treatment in cases of great deformity is that of Ollier,

and known as "decortication of the nose," in which the osteo-cartilaginous skeleton of the nose is dissected throughout its entire extent from the hypertrophy by the knife, and the raw surface dressed with Iodoform and allowed to granulate.

ACROMEGALY.

No treatment is of avail in this rare and interesting deformity. The enormous growth of the hands and face proceeds steadily in the presence of large doses of Iodides and the other drugs hitherto tried in vain. Ruttle has given great relief to several painful symptoms in a case of this affection by using Exalgine, and it is reported that improvement has followed the administration of Antipyrine and Arsenic. Attempts have been made to treat the affection by administering extract obtained from pituitary gland, but the results are unsatisfactory. In some cases the administration of thyroid extract has given considerable relief, but no permanent cure has been reported.

ACTINOMYCOSIS.

In preventive treatment absolute cleanliness is all that is required. As soon as the disease appears in man it should be met by complete removal by surgical methods when these are possible. Wherever the characteristic yellow grains, visible to the naked eye, are found, the abscess cavity containing them should be freely incised, and not a trace of the affected tissue left. It should be scraped with a curette or destroyed with the cauter. When the disease attacks the alveolar process of the jaw, this should be removed by the curette, knife, gouge, or saw. When it has crept into the interior of the hollow bones of the face, these should be opened up by the chisel and gouged out, and after the application of a strong caustic, packed firmly with Iodoform gauze, and permitted to heal up from the bottom.

The entrance of the fungus through decayed teeth should always be looked for in doubtful cases. The sooner its presence is detected the more efficacious is treatment. Actinomycosis of the lung has been treated by cutting down and resecting the lung, but little hope is to be expected from such a serious measure.

It has been proved that in cows the application of a strong tincture of Iodine to the incised tumours, with the internal administration of Iodide of Potassium, is curative. Iodine caustic has a powerful destructive action on the parasite, and several cures are reported. Ferric Sulphate, Sublimite, Phenol, Iodine, and Zinc Chloride have given good results. Ziegler injects Protone. Bilroth cured a case by injecting Tuberculin, and Moorhead injects Teucin.

The list of recoveries following the internal administration of Iodide of Potassium is now a long one, and the drug is by some held to be a specific. This can only be true when the disease is found in the very early stage. The dose should be 15 to 20 grs.

three or four times a day, and surgical procedures always should be undertaken in a few weeks if improvement be not evident. This method is more likely to prove useful when the tongue is affected. Good results have followed injections of the iodide into the nodules, followed by decomposition of the salt with a current of 50 milliamperes by Gaultier's process in regions where excision would cause facial deformity.

ADDISON'S DISEASE.

Anæmia should be combated by Iron and Arsenic. Vomiting should be treated with gastric sedatives like Bismuth, and loss of appetite with Tonics. Fagge suggested Iodine both internally and externally. Purgatives must be avoided.

In hospital or private practice the writer has never seen any benefit from any drug which he has used, and Chloride of Gold, Nitrate and Oxide of Silver, Arsenic, Antipyrine, and many other substances were prescribed without effect.

Assiduous and even forced feeding seems to check the progress of the disease for a time till the stomach gives up. Fatal syncope must be guarded against by keeping the patient in the recumbent position for long periods.

Advance has been apparently made in treating this disease by administering the suprarenal capsule of the sheep or an extract prepared from it. The dose should not exceed about 1 dr. of gland or its equivalent in extract. The results, though hopeful, are not very satisfactory as regards ultimate recovery, but they show that the dangerous fall in blood pressure may be corrected for a time at least by the administration of the gland extract, and pigmentation has been found to decrease. Oliver has noted that when this treatment is interrupted pigmentation begins to increase again. The medulla of the gland is the only active part, the cortex being inert. Thymus gland has been suggested.

ADENOIDS.

Owing to the serious consequences which their obstruction causes to nasal breathing, these growths should always be promptly dealt with before deafness, ear suppuration, and other complications arise. In very mild cases attention to health, change of climate or environment, may possibly at the early stage cause them to disappear, but this must be recognised as an unlikely result, unless in the case of children approaching puberty, when these growths spontaneously atrophy. Surgical treatment is indicated in the great majority of cases, and this may be effected by the finger nail where the growth is easily reached and limited, and as a rule slight chloroform narcosis will be necessary. Several deaths have been recorded from chloroform, and many operators, including Hunkel, refuse to use it. Cocaine may be used locally alone or with Antipyrine. The child's head should project beyond the operating table, where it can be depressed so as to permit

any bleeding to occur into the mouth, and the growths can be removed by the curette passed up behind the velum. Dalby operates in the upright position with the patient leaning forwards, and he uses either Gottstein's instrument is the most convenient, though some operators prefer Lowenberg's forceps. Sometimes the vegetation can be readily removed by a straight curette passed through the anterior nares without chloroform. When the scraping is completed the index finger may be inserted, and any remaining growths detached by the nail. Great gentleness should always be exercised, as many deaths from secondary hæmorrhage have been recorded, and the internal carotid artery has been found torn in more than one fatal case. In using the forceps it is necessary to avoid grasping the septum.

AIR PASSAGES, FOREIGN BODIES IN.

The foreign body should be removed at the earliest possible moment. Thoroughly cocaineise the pharynx and larynx, then pass the index finger into the throat, and if the substance is lodged about the entrance of the larynx it may be removed by forceps or the fingers, inversion of the body and slapping between the shoulders may be tried with some hope of success. Where the foreign body has entered the larynx, in the absence of spasm it may be removed by forceps guided through the aid of the laryngeal mirror. Where these attempts fail, *laryngotomy* must be immediately performed when the symptoms are acute, and this can be readily accomplished with any cutting instrument at hand by making a vertical incision about 1 inch long in the middle line between the sterno-hyoid muscles, and a transverse incision through the crico-thyroid membrane, which can be easily felt through the skin.

Where the foreign body has passed into the trachea or bronchus the first step is to try inversion, but this should never be done unless everything is in readiness for opening the trachea, as there is great danger of the body becoming lodged in the glottis and causing sudden death, and when this fails, as is generally the case, the surgeon should perform *tracheotomy*, making an unusually free incision through the tracheal walls, which should be held widely separate by hooks to facilitate the expulsion of the offending substance. This may be hastened by inverting the body and applying a smart slap with the open hand between the shoulders.

When the foreign substance does not come through the tracheal wound or through the glottis, gentle efforts may be made to remove it by a loop of fine wire passed into the trachea, or by forceps. Should this fail the tracheal wound must be kept open by silk threads passed through its edges and tied round the neck, when the surgeon can afford to wait a few days, since the opening in the trachea removes any immediate danger of suffocation. Afterwards forceps may be used.

Small bodies which could not otherwise be detected have been successfully localised by aid of the X Rays.

Foreign bodies in the gullet are removed by the methods detailed under *Œsophagus*.

ALBUMINURIA.

Since this condition will be found in more than 50 per cent of the cases to be dependent upon Bright's Disease, its treatment will be mentioned under that head. In those cases where albumin appears in the urine, apparently independent of renal disease, it may (speaking generally) be said to be in such small amount as not to call for any special treatment. Where, however, more than a trace is pretty constantly detected, the physician should determine the *cause* and treat it. If, as is common, the albumin appears as the result of defective assimilation of albuminoids, attention should be at once directed to the state of the digestive organs, and especially the liver; and there is no more potent remedy in such cases than a strictly milk diet, with or without Pepsin. Home-made Koumiss, prepared by mixing $\frac{1}{2}$ pint of water, $\frac{1}{2}$ pint of butter-milk and four pints of Fresh Milk, and 1 oz. Loaf Sugar, leaving in a warm place and shaking occasionally for 26 hours, will make a palatable draught, very suitable in many cases. Albuminuria occurring during febrile attacks, zymotic diseases, inflammatory affections, &c., will yield to the remedies suitable for the primary disorder. When depending upon obstruction to the circulation, as in valvular affections or cirrhosis, the albumin will disappear upon the removal of the cause when possible. Cardiac tonics and diuretics, by strengthening the heart muscle and stimulating the renal blood-vessels, may cause its disappearance. The wet pack is very serviceable in such cases.

Arsenic and Iron, separately or combined, are of great value in the treatment of chronic albuminuria, especially when the drain of albumin has produced a marked effect upon the blood. Iron affords the best results in albuminuria depending upon a morbid state of the blood, as in scurvy, pyæmia, and hospital gangrene. The albuminuria of adolescence, or so-called intermittent or functional albuminuria, generally yields readily to rest in bed and a strict milk diet for a few weeks. In those cases where the albumin appears after physical exercise, Yeo lays stress upon the importance of limiting this to several very short walks, and forbids all athletics and animal food. Sexual excesses, smoking, over-feeding, brain-worry, exposure to cold, and other possible causes must be guarded against. It is hardly necessary to remind the student that albuminuria depending upon discharges finding their way into the urine from the urethra, prostate, bladder, or pelvis of the kidney, can only be treated by surgical methods directed to the diseased conditions in these localities. As a rule, the broad statement may be accepted as true that no drug possesses the specific power of markedly causing diminution in the quantity of

albumin, and it is better for the physician to attack the cause than to lose time in administering the usual list of mineral and vegetable astringents. Moreover, some authorities affirm that their use is positively injurious.

Caffeeine, Lime Water, Copaha, Echinin, Gallic and Tannic Acids, Tannalbin, Glonoin, Hydrastis, Acetate of Lead, Ergot, Cantharides, Alum, Chloride of Gold, Chloral, Chloride of Sodium, Turpentine, and a host of other remedies have each, in somebody's experience, been found to markedly diminish the amount of albumin but when tested fairly have been generally found to fail. The hopes entertained of Strontium have not been realised.

The albuminuria of pregnancy when slight or transient, does not call for medication; when persisting and copious, it may be safely dealt with as if occurring in Bright's Disease (which see).

ALCOHOLISM.

The *preventive* treatment of drunkenness is a very wide and serious question; and notwithstanding the heroic attempts of philanthropists and the activity of temperance reformers, the exhaustless literature of the subject, and the introduction of costly and cumbrous State machinery, little or nothing seems to have been accomplished, when one considers the terrible importance of the issue. Though the writer is very conscious that a great problem like this can scarcely be mentioned, much less discussed, in a Handbook of Treatment, nevertheless he cannot refrain from stating his conviction—the result of years of observation upon the action of alcohol—that it is possible for vast and far-reaching results to be obtained by a State regulation of the strength of all distilled alcoholic liquids to be used as beverages.

If whisky, brandy, rum, and gin could only be procurable in alcoholic strength, say of the average strength of claret (10 per cent.), more progress would be made in the amelioration of the evils of the drink curse than in all the temperance legislation of the last century. The benefits would be at once obvious in the great manufacturing centres where alcohol is largely consumed in a concentrated form. The writer is satisfied that the consumption of spirits in a strong or only slightly diluted condition enormously increases the danger of the establishment of the alcohol habit in its worst forms, and enormously increases the injury to the tissues and glands of the body. The difficulty in carrying out such a law would be great at first, and might seriously interfere with Exchange returns, but the gain to the nation would be obvious. The increase in the productive power of labour would be immediate, and the diminution in the expense of the maintenance of the huge army of useless victims of alcoholic excess would in some years be no less certain. It is true that such a measure would not lessen the evils of beer and wine drinking, it is probable that these might show an increase, but

the gain to Ireland, Scotland, and many centres in England would be certainly incalculable.

In the acute stage of drunkenness, falling short of alcoholic poisoning, the physician may be called upon to administer a remedy to counteract rapidly the symptoms of alcohol. The Solution of Acetate of Ammonia, in doses of a wine-glassful every 15 minutes, will often cause the uproarious or maudlin stage of drunkenness to give place to a condition of perfect sobriety in a surprisingly short time. 1 dr. of Carbonate of Ammonia, dissolved in 2 oz. Vinegar, makes an efficient substitute.

The hypodermic injection of $\frac{1}{4}$ gr. Pilocarpine will act with equal rapidity, and it can be administered when the patient refuses, or even when he is unable, to swallow the bulky, unpleasant solution. Cocaine, Kola Nut, Caffeine, and very strong Coffee produce somewhat similar results, but much more slowly and less satisfactorily.

If coma has already occurred, the stomach pump must be used, and Cold Affusion or Galvanism resorted to. (See under Poisoning.)

Acute gastritis following a debauch, and leading to serious vomiting is best met by a large blister over the stomach, and by the administration of small quantities of ice by the mouth, and Morphia hypodermically, or by the following mixture :—

R. *Bismuthi Carb.* $\mathfrak{z}\text{ij}$.
 Acid. Hydrocyan. $\text{Dil. } \mathfrak{z}\text{j}$.
 Mucilag. Recentis $\mathfrak{z}\text{ss}$.
 Liquor. Morphine $\mathfrak{z}\text{ii}$.
 Aque Chloroformi $\text{ad } \mathfrak{z}\text{iv. misc.}$

Fiat mistura. Capiat cochleare min. omni hora, p.p.a

If there be no collapse or severe pain, the stomach should be washed out with 40 oz. water, in which 5-10 minims of Creosote have been dissolved. In the chronic vomiting, Creosote capsules, $\frac{1}{2}$ gr. of Morphia in minute pill, or minim doses of Fowler's Solution, or 10 grs. Bismuth and 5 grs. Heavy Magnesia, may be given. The writer has often seen vomiting stop after 10 to 15 minim doses of Tincture of Capsicum, which had been given to allay the craving. By far the best food at this stage is good buttermilk turned acid, and if very acid it can be freely given with kail water, and this combination may stop vomiting which has resisted all treatment. The fluid known in Ireland as buttermilk differs widely from the vile compound known by the same name in most parts of England, where only the cream and not the entire bulk of the cow's milk is churned.

The chronic dyspepsia of drunkards is a troublesome affection, in which drugs are of little value. The great difficulty experienced

by the physician is to select some form of liquid nourishment which can be taken copiously by the patient at short intervals, which will be easily digested and acceptable to the vitiated palate. There is nothing better than the buttermilk just mentioned, which may be given in unlimited amount. It may be administered every 15 or 30 minutes, either alone or mixed in equal quantity with fresh milk, soda or kali water. The formula mentioned upon page 26 for preparing artificial koumiss will be found a palatable and nutritious liquid. Where buttermilk is not attainable the Koumiss prepared with yeast and cow's milk may be employed. (See Seventh Edition of author's "Materia Medica," pages 555—557.) The writer has been informed by a medical man who had successfully overcome the alcohol habit in his own person, and has had considerable experience in treating others, that he found great assistance from the variety of the "Hop Bitters" which contains no alcohol. Carefully-prepared beef tea and chicken soup either of which can be thickened with barley water, and fortified with Liebig's Extract of Meat, or ordinary clear or thick soup of any kind that the patient may fancy, can be freely given. If there be great weakness or prostration, and the stomach refuses to accept any nourishment, except in very small quantity, Bovril, Valentine's Meat Juice in drachm doses every half hour, or Brand's Beef Jelly, with ice every hour, affords the best chance of tiding over the difficulty. Associated with gastric symptoms is the intense craving for alcohol in some form. This should be stoutly withheld. The physician generally sees the patient after he has been indulging freely for a considerable period, and alarm has been excited by the depression produced by continuous vomiting or by the dread of delirium tremens. The serious difficulty which at once confronts the attendant is the responsibility of cutting off the stimulant. There is a deeply-rooted prejudice against this line of action held both by the unfortunate victim and his friends, and, if such a step be taken, any mishap occurring is sure to be attributed to this point in the treatment.

In the vast majority of cases this is the correct course to pursue. The experience of good surgeons proves how constantly immediate improvement sets in, and how exceedingly rarely does any mischief follow the abrupt withdrawal of stimulants, even in the broken-down patients committed to prison for some act perpetrated during their prolonged debauch.

This prejudice has, to a large extent, arisen from the aversion to alcohol often noticed in patients just before symptoms of delirium tremens set in at the end of a drinking bout. The supervention of the delirium is attributed to the cessation of stimulation, whilst, in reality, it is but a symptom of the disease. The prejudice is also traceable to the memory of the horror and depression caused by the cutting off of the stimulant in former attacks, and the patient is generally loud in his protestations that death will follow the sudden withdrawal of his liquor.

Though the physician should act firmly in insisting upon this complete withdrawal, he will be wise to postpone it for a short time if he has good reason to suspect that symptoms of delirium tremens are about to immediately declare themselves.

Exception should be made in those very much debilitated from disease, especially in those suffering from heart affections, and in the aged. If the pulse should exhibit marked signs of weakness and irregularity, if there has been prolonged insomnia; or if the history of the patient shows clearly that he has for years been taking alcohol in moderate doses daily before his recent excess, then small regulated doses of alcohol should be administered to him at stated intervals, the dose to be proportional to his habits. Generally speaking 12 oz. of whiskey should be rarely permitted during the 24 hours, and 6 oz. for all cases may be said to be a fair allowance during the first few days, though the patient may have been in the habit of taking much larger quantities.

If there is much gastric irritability Champagne may be given, but all other wines should be forbidden. Good whiskey alone being selected as the stimulant, the rule should be laid down that it must be taken by the patient mixed with his soup or milk by a reliable nurse.

In the great majority of instances, however, the physician when called to treat a case of chronic alcoholic poisoning will be safe in fearlessly acting as he would in any other case of poisoning—by immediately preventing the administration of the poison. Much can then be done with the assistance of a firm nurse, who should administer liquid nourishment every 15 or 30 minutes.

The following may be given with benefit to allay the craving for alcohol, and to some extent it takes its place.—

R. *Spt. Ammon. Aromat. ad* ℥iv.
 Tinct. Cinchonæ ℥ij.
 Liquor. Strychninæ Hyd. ℥j.
 Tinct. Capsici ℥j. *misce.*

Fiat mistura. Sig.—"A large tea-spoonful in half a tumblerful of effervescing potash water every hour."

Or the following may be tried.—*Ext. Cocæ Liq.* 2 oz.; *Tinct. Card. Co.* 2 oz.; *Tinct. Cinnamon.*, 1 oz.—one tea-spoonful every hour in water.

Or the following.—*Tinct. Jaborandi*, 5 drs.; *Tinct. Chiratae*, 2 oz.; *Aquæ ad* 20 oz.—one dessert-spoonful every quarter of an hour.

Attention has of late years been directed to the value of Strychnine and Nux Vomica in the treatment of alcoholism and delirium tremens. The author first pointed out in 1882 the striking effects of alcohol in Strychnine poisoning, and published

a case where recovery followed after the failure of the recognised remedies. He is satisfied that in strychnine we have a remedy of great value to act as an antagonist to alcohol, and he finds that it affords the best results of all drug treatments in diminishing the craving for alcohol and preventing the depression following its withdrawal. In all cases it should be pushed, and though relapses occur as a rule, the physician can depend upon it in helping the patient till moral influences have time to operate in his reform. The drug may be given hypodermically ($\frac{1}{2}$ gr.), while smaller doses are administered by the mouth. Many so-called "Alcohol Cures" contain Strychnine, some contain Brucine and Gold Salts, and a few Atropine, but the majority contain large percentages of Alcohol.

Coca leaves and Quassia chips may be chewed during the intervals between food and medicine.

After the relief of the more acute symptoms, tonics, as Quinine with a Mineral Acid and Gentian and Calumba, may be given. If the gastric symptoms continue after the disappearance of the craving, Bismuth or Oxide of Zinc, with a minute dose of Morphine, $\frac{1}{8}$ gr., may be given; or, Pot. Bicarb., 1 oz.; Aquæ Lauracerasi, 6 drs.; Aquæ to 12 oz.—a table-spoonful, with an equal quantity of fresh lemon juice, every 2 hours.

For the persistent loss of appetite and want of energy, associated with restlessness and disturbed sleep, sometimes with traces of hallucinations following long after prolonged alcoholic excess, there is no better remedy than the following:—

R Quinina Sulphatis gr. xxv
Acid. Nitro-Hyd. Dil. ℥vj
Ext. Cinchonæ Liq. ℥ij
Aquæ Destillatæ ad ℥x. misc.

Fiat mistura. Capt. coch mag. ter die ex aqua ante cib

For the insomnia of chronic alcoholism, Opium should be sparingly employed. Bromides may be freely and continuously employed, and 10 to 30 grs. may be given in conjunction with any of the above combinations. It is a good plan to give the Bromide of Potassium in doses, say of 20 grs. every 4 or 6 hours, alternating with the Sal Volatile and Capsicum Mixture. Trional, Sulphonal, Paraldehyde, and Hyoscin are all safe and useful. Chloral should never be trusted, owing to its dangerous depressing action upon the heart. (For the treatment of insomnia in delirium tremens see under Delirium Tremens and Insomnia.) Long after alcoholic excess has terminated in the condition requiring the treatment mentioned in the previous pages, the patient should be seriously cautioned, and, if necessary placed under mild restraint, and if the craving continues, and the will be

unable to resist it, restraint should be insisted upon, and a residence in a good inebriate asylum be strongly advised for as long a period as possible. Hypnotism has been extolled, but the writer has no experience of its use.

Dipsomania must not be confused with ordinary inebriety. The mental or psychic element must be always before the mind of the physician when dealing with this disorder, and its victim must be treated and assisted as if he were the subject of a nervous or degeneration either inherited or acquired. In the hands of Dr. M. Bramwell hypnotic suggestion in these cases has given marked and satisfactory results. In every case total abstinence from all forms of alcoholic beverage must be rigidly insisted upon.

The treatment of the various diseases and conditions following upon chronic alcoholism may be found under Cirrhosis, Delirium Tremens, &c.

ALOPECIA—See Baldness.

AMAUROSIS.

Accepting this term as only including those cases of *total blindness* associated with atrophy of the optic nerve without any evidence of disease or change in the media or coverings of the globe, it will be apparent that but little can be achieved by treatment. A condition depending upon so many widely different causes, all tending to eventuate in a complete white atrophy of the disc, will require very careful discrimination as to the diagnosis of the exact factor at work in each case. If complete white atrophy has not already occurred, sometimes the physician can do a great deal.

In amaurosis following diphtheria and scarlatina, if the case is recent, Strychnine should be freely given, and as a rule its administration by the mouth should not be attempted, but at once the hypodermic injection of $\frac{1}{16}$ to $\frac{1}{4}$ gr. daily should be persevered with for some weeks. There is some hope that this measure may be of use even in traumatic cases, and good results are obtained in amaurosis after lead, tobacco, and alcoholic poisoning, where already the case has passed out of the category of amblyopia. The Strychnine treatment may be supplemented by a cautious use of the constant current, not more than four Leclanche cells being used, and it is a good rule to begin with two, one pole being placed at the occiput and the other over the eyebrows. If there be evidence of syphilis as a cause, rapid mercurialisation or large doses of Iodide of Potassium may be tried, though it is doubtful if ever success has followed such treatment.

In quinine amaurosis depletion has been advised, and Nitrite of Amyl followed by Digitalis and Hydrobromic Acid, has given good results.

In those rare cases where amaurosis has rapidly supervened upon the sudden suppression of some long-standing discharge, as at the climacteric period and after the removal of bleeding tumours, some hope may lie in free purgation, and the introduction of a seton or blister over the brow. The administration of Arsenic (5 minims of Fowler's Solution) may be continued at the same time that the hypodermic injections of Strychnine are being given. Chloride of Gold and Sodium (U.S.P.) in pills containing $\frac{1}{2}$ gr. may be given 4 times a day, and in a few cases good results have been recorded.

Pilocarpine, $\frac{1}{4}$ gr. hypodermically, has, in a few cases, been followed by benefit, and the same may be said of inhalations of Nitrite of Amyl and large doses of Santonin at bed-time.

AMBLYOPIA.

Many cases of dimness of vision or defective sight, without marked visible changes in any part of the eye, have been proved to be caused by tobacco, alcohol, or lead poisoning, and a few have been known to owe their origin to the continued administration of large doses of quinine, filix mas, iodoform, bisulphide of carbon, nitrobenzol, and arsenic; sometimes malarial poison has been the cause.

For tobacco amblyopia, or tobacco amaurosis, as it is more commonly called (though the latter term should be confined to those cases where there is total blindness, which is rare), the first thing to do in the way of treatment is to stop immediately and completely all use of tobacco. In the case of young smokers this will often effect a speedy cure, but in those where the habit has been long established, and especially where there are found some evidences of disc atrophy, the affection may prove very difficult to deal with, and even in spite of treatment may, in rare instances, pass into permanent amaurosis. In addition to abstinence from tobacco and alcohol, everything that improves the general health and tone should be advocated. General tonics, especially Strychnine in mild cases and in severe ones the hypodermic injection of $\frac{1}{4}$ gr. of this drug under the skin in the region of the temple daily. Sulphate of Zinc in 5 gr. doses may be given internally after each meal whilst the Strychnine treatment is being carried out. Tea-spoonful doses of Easton's Syrup may be commenced when the hypodermics are stopped, which should be soon after decided improvement sets in.

A careful administration of the induced current is always advantageous.

Pilocarpine subcutaneously has given good results in many cases. It may be occasionally administered during a course of Strychnine. Nitrites have been recommended, but their effects are too transient to be of permanent value. Nitroglycerin should, however, always be tried.

Amblyopia, caused by chronic alcoholism, will require to be dealt with upon the same lines—the total abstinence from alcohol in every form being rigidly insisted upon. Everything that can improve the general health, as changes of food, air, and scene, sea bathing, and rest to the eyes are to be recommended, and the judicious administration of tonics, chief amongst which is Strychnine, or the employment of hypodermic injections of this drug in severe cases. The writer believes that, where the affection is of long standing, the best treatment is to persist in the internal administration of $\frac{1}{2}$ gr. of the Chloride of Gold and Sodium in pill, after a few weeks' treatment by Strychnine, with occasional hypodermics of $\frac{1}{2}$ gr. Pilocarpine.

Often alcoholic and tobacco habits exist in the same person, and, of course, where amblyopia supervenes, both habits must be stopped entirely. Quinine amblyopia may be treated in a similar way, though the above remedies are seldom required, as the affection of sight rapidly disappears after discontinuing the use of the drug. (See under Amaurosis.)

Amblyopia caused by lead poisoning will require for its treatment similar measures directed to the improvement of the general health. Iodide of Sodium, in full doses largely diluted, affords the best results; it may be advantageously combined with Sulphate of Magnesia. It is a good plan to cause gentle purgation with the Sulphate of Magnesia in lemonade made with Dilute Sulphuric Acid, whilst the Iodide treatment is kept up constantly. Sulphurous baths are also of great use. It is needless to say that every caution must be employed against the further introduction of the poison into the system, by great personal cleanliness, &c. The constant current is often of much benefit. The state of the kidneys will require attention, and, if albuminuria be present, the possibility of uræmia must be remembered, and appropriate treatment at once resorted to, with the view of causing elimination of the urea and other compounds by the skin and bowels. (See under Plumbism.)

Amblyopia coming on during pregnancy must be carefully watched, and if the ordinary treatment by purgation and hot packs does not afford relief, as in the case of acute Bright's Disease, and should the amblyopia be passing into amaurosis, at once premature labour should be induced, and free purgation kept up afterwards till all visual troubles pass off, and the swollen and congested disc assumes its normal appearance. (See under Bright's Disease.)

AMENORRHOEA

Arises from so many different causes that a resumé of its treatment will necessarily embrace an extensive list of drugs of widely differing actions.

Emmenagogues may be regarded as remedies which, either by direct or indirect means, promote the menstrual flow. The flow

may be diminished or absent through purely constitutional conditions, as plethora or anemia, in which cases the treatment will differ widely—the *indirect* emmenagogue action of cathartics being indicated in the case of plethora and the free administration of ferruginous compounds, which act as indirect emmenagogues, in the case of anemia. Whilst, again, the flow may be absent or diminished through purely local causes, when the action of a *direct* emmenagogue like Ergot will be indicated.

In those cases where the menstrual flow has *never* appeared, the cause may be found in some *malformation* or in *absence* of development of the sexual organs. If the latter, the case hardly can be hoped to come into the sphere of treatment whilst, if menstrual discharge has been poured out into the vagina or interior of the uterus and retained because of an imperforate hymen, or atresia, or occlusion of the cervix, os, or vagina, the case falls under the care of the surgeon. In atresia, where owing to absence of a considerable portion of the lower part of the vaginal canal there is no hope of tunnelling out a new passage, it is better to tap the distended *sac per rectum*, and leave a free opening for the accumulated flow and a constant exit for future discharge by the anus.

Where the occlusion is low down and there is but a thin layer of tissue closing the perineum, the treatment will be the same as if an imperforate hymen was the cause of the retention, i.e., a free crucial incision. The tarry fluid should be allowed to flow spontaneously, and no pressure should be employed, but gently syringing with a weak solution of Perchloride of Mercury (1 in 5000) will be advisable. Murrell testifies to the value of a zinc and copper stem pessary in cases where there was retarded uterine development.

If the case be one of merely delayed appearance of the first flow, not depending upon structural peculiarities, the physician should hesitate before yielding to the anxious solicitations of friends to begin active treatment by powerful emmenagogue remedies, always remembering that the menstruation may be delayed long beyond the average age without any harm whatever to the patient, especially in cases of slow physical development, or where the amenorrhoea is depending upon phthisis or Bright's disease.

If the patient appears in every other respect in perfect health, it would be wiser for the physician to refrain from the use of drugs entirely, and recommend change of air and scene and active outdoor exercise. Should, however, anemia or plethora, or any other diseased condition, or any departure from health be noticeable, it should be at once attended to, after which the physician may wait before employing any remedy intended to act as a direct stimulant to the uterus until there is some indication of an attempt upon the part of nature to establish the menstrual flow. This may be recognised by some of the usual symptoms preceding menstruation, such as headache and flushing of the face, with

bleeding from the nose, sense of fulness in the breasts, backache, and general malaise coming on periodically.

The hot turpentine bath (about 103° F.) should be resorted to, the patient put to bed and covered with warm clothing. Often a good hot foot bath of mustard and water along with hot fomentations to the loins answers well, or a large hot linseed meal poultice, with mustard, applied to the lumbar region for a few hours every evening, may establish the flow. It is an excellent plan to give a local hot mustard pack by wringing a small blanket out of hot water and mustard and enveloping in it the lower half of the body and legs, and putting the patient to bed. This treatment may be continued once a day for three or four days at a time, and it will be well to supplement it by giving about 1 oz. of gin or whiskey with a tea-spoonful of Tincture of Saffron, or 10 minims of Oil of Pennyroyal or Peppermint with hot water. Rue and Savin are drugs of great power, and should seldom be given. The Oil of Parsley, in capsules containing 5 minims, is unobjectionable.

Phos. pine given hypodermically in doses of about $\frac{1}{4}$ gr., whilst the patient is in the pack, will be found highly efficacious.

If the molimen is ushered in with hot skin and fever, small doses of Aconite or Cimicifuga given every hour ($\frac{1}{4}$ min. of tincture of aconite or $\frac{1}{2}$ min. of tincture of cimicifuga) will afford relief.

In those cases where the symptoms of menstruation are absent or only vaguely marked—in other words, where there is no indication of a molimen, and menstruation is delayed for a long period after its first appearance is naturally expected, unless the patient is really plethoric, it will be a wise routine practice to saturate the system with iron. The number of preparations at the hands of the physician for this purpose is almost endless, but the best is Bland's Pill, of which 2 or 3 should be given 3 or 4 times a day after meals. Next in value is the preparation known as Dialysed Iron, of which 30 minims may be given 4 times a day. Griffith's Mixture, or a combination of 15 minims of the B.P. Tincture and 2 minims of Fowler's Solution, is often of great value. Notwithstanding the often repeated statements about the superiority of the organic salts of iron in practice the older preparations still hold the field.

If constipation be present, the Decoction of Aloes may be given with an iron preparation, or the Pill of Aloes and Iron or Aloes and Myrrh may be employed, to which Asafetida may be added with advantage. The following is an excellent formula, *i.e.*, Reduced Iron, 2 grs.; Arseniate of Iron, $\frac{1}{4}$ gr.; Aloin, $\frac{1}{4}$ gr.; Extract of Nux Vomica, $\frac{1}{4}$ gr.

Even in the presence of distinct plethora, a mixture containing 3 grs. of Sulphate of Iron and 2 drs. of Sulphate of Magnesia in each dose, given every 4 or 6 hours, often establishes the appearance of the flow, the first discharge appearing after free purgation.

Electricity.—In the class of case just considered, *i.e.*, where

menstruation has never appeared, and where no molimen is evident, and where the patient's health is apparently good, and there is no dwarfing of body or malformation of sexual organs, there is no remedy to be compared with the constant current. Beginning with 10 Leclanche cells with the negative pole on the sacrum, and a large flat positive electrode upon the front of the abdomen, taking in both ovarian regions, the current may be increased to 30 cells ultimately, though 20 will be found enough for ordinary purposes when administered for 15 minutes daily. The portable constant current batteries are a source of disappointment, and the writer advises every physician to have a battery of large Leclanche cells permanently fixed up in his study. Some authorities recommend one electrode (negative) to be placed in the vagina in contact with the os and the other externally over the uterus.

The Faradic current is also valuable, one pole being placed over the sacrum, and the other alternately over each ovarian region. It will seldom be found necessary to introduce a rhizophore up to the fundus, nor will it be found advisable to introduce a galvanic stem intra-uterine pessary.

In amenorrhœa occurring in patients in whom the menstrual flow had been established for a considerable period, it will be the duty of the physician to look into the cause of the suppression, and find out the error in health which is at work in suppressing or diminishing the flow, always remembering the possibility of pregnancy as a cause.

In the majority of cases anæmia or chlorosis is present, and iron will be our sovereign remedy. Its best and most constant effects are seen in those bloodless patients where the flow, though never for long absent, is nevertheless reduced to a mere trace each monthly illness. 6 or 8, or even 12 of Bland's Pills in the 24 hours will often effect a cure both of the anæmia and of the obstinate constipation associated with it. The following is a useful combination —

R *Liquor. Ferri Dulcis.* ℥ii.
 Glycerin. Purif. ℥i.
 Tr. Nucis Vomicae ℥iij.
 Ext. Casearæ Liq. ℥iv. misce

Fait mistura. Sumat ℥j. ter in die ex aqua post cib.

Or 10 grs. of the Ammono-Citrate in 4 drs. of Cinnamon Water. It is always well before beginning a course of iron to order a few morning purges of Rochelle Salt, 6 drs., or Epsom Salt, 3 drs.

The diet should be carefully looked into, and only the plainest food permitted, and, as a rule stimulants prohibited. The clothing should be warm, and woollen stockings with thick-soled boots

should be worn, and active outdoor exercise must be insisted upon.

If in spite of such general treatment the menstrual discharge fails to appear at the proper time, the treatment by hot baths and mustard packs is to be commenced at about the time when the absent or habitually scanty flow is expected, and failing the success of these remedies, the so-called emmenagogue drugs are indicated.

In amenorrhœa with mental depression and from mental shock, there is no treatment from which the re-establishment of menstruation can be predicted. Change, fresh air, exercise, food, and tonics are the great therapeutic agents. Of these, change is the essential.

The following drugs are in repute as emmenagogues in amenorrhœa —

Ergot will be found a most disappointing drug generally, but success sometimes follows after a few weeks' trial of a pill, three times a day, consisting of 1 gr. Ergotin (Bonjean's), 3 gr. Ferrum Redact., 1 gr. Aloes Socot.

Rue and Savin in 3 minim doses of the essential oils, 2 or 3 times a day, about the expected period have been recommended; they sometimes cause great irritation and pelvic disturbances.

Santonin in doses of 5 to 10 grs. given at bed-time for two or three nights has been highly recommended. It often fails, and it should be remembered that it is dangerous, death sometimes following full doses of the drug. It is safer when given along with castor oil.

Quinine in 10-15 gr. doses may be tried; any benefit to be expected from it will probably appear after one or two doses.

Hellebore is not to be recommended save in cases where the flow has been suddenly suppressed; small doses of the Tincture of Green Hellebore, 2 minims every hour, will act sometimes after 6 or 8 doses in strong plethoric subjects. Aconite and Cimicifuga may be used in the same way.

Apioi in capsules, containing 3-5 minims, is often serviceable, and is not likely to do any harm.

Potassium Permanganate is a very uncertain agent. Ringer and Murrell extol it in both anemic and plethoric cases where the flux is delayed or scanty, or suddenly suppressed. 1-2 grs. should be given in a pill three daily till the catamenia appear, when its administration should be discontinued till within 4 days of the next expected period. Peroxide of Manganese or the Lactate may be tried in similar doses.

Cantharides, though a dangerous remedy, is still used occasionally to promote the menstrual flow. The dose should commence with 1 minim of the tincture in well diluted mixture three times a day, and be increased to 8 or 10 minims cautiously. The writer has, however, never used it, and probably never shall use it for this purpose.

Pennyroyal (*Mentha Pulegium*) is a favourite domestic emmenagogue which, in doses of 10-15 minims of the essential oil, often acts as a special stimulant to the uterus and ovaries, and it is safe and may be given in weak hot punch at the time of the expected flow.

Guaiacum is a valuable emmenagogue in young women where the menstrual discharge fails to return after rheumatism or rheumatic fever. 10 grs. may be given in fine powder mixed with marmalade or in sherry. The Ammoniated Tincture may be given with the Tincture of Aloes in 20 minim doses.

Iodide of Potassium in full doses, 10-25 grs., occasionally succeeds in restoring the catamenia when other remedies have been given up.

Jaborandi is a remedy which causes hemorrhage from the uterus when given hypodermically (as $\frac{1}{2}$ gr. Pilocarpine), and good results follow its use in amenorrhœa where the flow stops without apparent cause. The dangerous depression which sometimes follows large doses appears, in the writer's experience, to be reduced to a minimum if given when the patient is in a hot air bath or local mustard pack.

Electricity though somewhat uncertain in its action, is a valuable emmenagogue where the flow has suddenly stopped or failed to appear. It is used in these cases in the same way as in those where menstruation has never been established. The application of the continuous current may be tried alone or in conjunction with any other treatment.

Massage will be found a valuable accessory to the ordinary emmenagogue remedies. The practice of uterine massage, as carried out by some operators, is not to be recommended. This is a very questionable proceeding in most cases, and would seem to be seldom if ever justifiable as a remedy in simple amenorrhœa. Massage of the abdominal walls alone, or in conjunction with electricity or any other treatment, is clearly a legitimate practice. *Passatilla*, *Aletris Farinosa*, *Boghane* (*Menyanthes trifol.*), *Sanguinaria*, *Senecio*, *Hydropiper*, *Cypripedium*, *Caulophyllum*, and a host of American vegetable drugs are loudly praised by those who, having given them in amenorrhœa and observed the flow to return, have been satisfied about their value.

Oxalic Acid, in $\frac{1}{2}$ gr. doses, 3 times a day, has many advocates. It certainly is a powerful uterine stimulant, but not free from danger.

Spas.—The warm saline baths of Ems, Carlsbad, and Kreuznach are very beneficial where there is any evidence of pelvic or uterine congestion, and the sulphur waters of Harrogate, followed by a course of the iron springs, are also valuable. Primont and Schwalbach iron waters are also often prescribed.

AMYLOID DISEASE—See Liver, Diseases of, and Bright's Disease.

ANÆMIA

Is but a symptom of many different diseases, and its treatment will necessarily imply a knowledge of the treatment of various diseases like albuminuria, syphilis, leucorrhœa, plumbism, hæmorrhoids, malaria, epistaxis, phthisis, gastritis, &c.

Great advance has been recently made in the classification of the different forms of anæmia by the brilliant researches of Ehrlich, Lorrain Smith, and many others. Though these have not yet very materially helped the therapist, it seems certain that we are within measurable distance of hoping for new aids to the treatment of such diseases as pernicious anæmia and the various forms of leukiemia.

The first object should be to stop the drain upon the system, whether this drain be blood lost by hæmorrhage of any kind or by excessive discharge of albuminous secretions; afterwards the application of the ordinary laws of health—good, easily assimilated food, open-air exercise, &c.—will be all that is required.

In acute anæmia where the patient is sinking from the loss of large quantities of blood, the operation of Transfusion of healthy human blood or saline solution may be imperative. When possible the human blood should be defibrinated by collecting in a glass vessel as it flows from the basilic vein, and, after whipping with a glass rod till the fibrin has entirely been removed, it may be injected through a warm syringe into either an artery or vein, preferably the basilic vein.

A suitable direct transfusion apparatus can be easily made out of Dieulafoy's aspirator, by having a duplicate of the fittings and rubber tube which is to bear the needle at one end and be attached to the end of the cylinder at the other. So equipped, the aspirator will bear attached to each projection at the end of the cylinder a rubber tube with a suitable mounting at its extremity for the insertion of any of the hollow needles or canulæ.

One needle being inserted into the basilic vein of the patient, the other is inserted into the basilic of the donor. It is certainly desirable that the aspirator and tubes and needles be filled with warm, normal Saline Solution (6 per cent Chloride of Sodium) before the introduction of the needles. This will diminish the risk of coagulation of blood about the joints of the instrument, and it will be injected at the first stroke into the patient's circulation. By keeping the needles or canulæ in situation and manipulating the stop-cocks, the blood flows from the arm of the donor into the aspirator, from which it is gently sent by the piston (on the reversal of the cock) into the veins of the patient. From 5 to 20 oz. may be injected at once.

It may be possible to successfully transfuse blood from one patient to another by simply using a flexible bent tube with suitable ends, through which the blood will be driven by the force of

the donor's heart. The greatest possible care should be taken to prevent the entrance of air during the operation of transfusion.

Of late years the operation of blood transfusion has been almost abandoned since it has been demonstrated that a warm sterilised normal Saline Solution answers the same purpose. A tea spoonful (1 drachm) of pure Chloride of Sodium should be dissolved in 20 oz. of sterilised water. 30 oz. may be injected into the circulation. A glass canula, 3 feet of rubber tubing, and a small funnel are all the instruments required.

Large quantities of the Saline Solution may be injected into the peritoneal cavity in desperate cases of acute anæmia, and the writer has injected 20 oz. into the cellular tissue of each thigh with success by using the ordinary aspirator. As the fluid is injected, gentle massage may be employed to diffuse it over the entire limb. Thus ensures rapid absorption, and with good assistance three or four pints may be as rapidly got into the circulation as by transfusion, with its rather formidable preparations. The ordinary aspirator needle answers well, and the inverted action of Dreulafof's instrument is simple and convenient.

Ziemssen gives defibrinated human blood by hypodermic injection, and rectal administration of defibrinated ox blood has been advocated.

Schafer draws attention to the marked action of Suprarenal Medulla in hæmorrhages where heart failure and shock are marked. The sterilised decoction, 5 grs. to 1 oz., may be injected into a vein or even into the heart itself in desperate cases.

In ordinary cases of chronic anæmia, after attention has been paid to any habitual hæmorrhage or discharge, and where the appetite is fair, the physician should attempt to assist nature in restoring the blood to its normal state by the administration of Iron in some form. After a smart saline purge, treatment may be commenced, but if the tongue be coated and appetite bad it will be necessary to follow the action of the purge with a bitter tonic.

Sometimes it will be found advantageous to combine the Iron with a bitter tonic as in the following:—

R. *Tinct. Ferri Perchlor.* ʒv.
 Quinine Sulph. gr. xl.
 Glycerin. Purif. ʒj.
 Aqua ad ʒiv. *misc.*

Fiat mistura. Capiat ʒi. ex aqua ter in die post cibos.

It is hardly necessary to remind the student that iron preparations should always be given after meals and diluted.

The Citrate of Iron with Quinine may be given in 5 gr. doses, in solution with a little glycerin or syrup and water. The following is a good combination in $\frac{1}{2}$ oz. doses:—*Ferri et*

Quinine Cit., 14 dr. ; Tinct. Nuc. Vom., 2 drs. ; Glycerin, 1 oz. ; Infus. Calumbæ ad 8 oz.

Should the anæmia be associated with neuralgia or nerve troubles, a tea-spoonful of any of the following syrups may be ordered in a wine-glassful of water after meals: Syr. Ferri Phosph. (Easton), Syr. Hypophosph. Co. (Fellows), Syr. Ferri Phosph. B.P. For children there is no preparation equal to tea-spoonful doses of Syr. Ferri Phosph. Co. (Parrish). Where struma is present the Syr. Ferri Iod. is indicated.

Constipation being present, 5 grs. of the Pil. Aloes et Ferri morning and night, may be given.

Should the anæmia be associated with chlorosis or amenorrhœa, any of the formulæ mentioned under Chlorosis or Amenorrhœa may be given.

In simple anæmia, where the physician wishes to order a preparation of iron as a blood restorative without running the risk of upsetting any of the organs or functions of the body, there are not any preparations, as pure chalybeates, superior to the Liquor Ferri Dialysatus, or to Bland's Pills or Bipalatinoids, or to the Ferrum Redactum.

The best results are obtained by giving large doses, and often success follows doses much too large to be assimilated in the body after small doses had been fruitlessly administered for a long time. The theories of the action of iron in anæmia and chlorosis is a most interesting subject, but it can only briefly be here referred to. For a long time it was believed that the iron was not absorbed, but that it, by its presence in the intestine, enabled the organic iron in the food to be absorbed and used up. Stockman has however, demonstrated that small hypodermic doses of the ammonio-citrate speedily cure bad anæmic cases. Other observers have demonstrated that the inorganic iron is absorbed from the intestines of fowls. The least bulky preparation of iron is the Ferrum Redactum, and for children the Saccharated Carbonate is a pleasant remedy. Of the former drug 7 or 8 grs. may be made into a moderately-sized pill.

Much benefit may be obtained by combining Arsenic with Iron in the treatment of anæmia, and this is best done by giving the arseniate in combination with reduced iron in a pill—Reduced iron, 5 grs. ; Arseniate of Iron, 1 gr. M. One pill morning and night. (These may be coated with Keratine.) Or

R. Tinct. Ferri Perchlor. ʒv
Liquor. Fowleri ʒij.
Glycerin. Purif. ʒj.
Aquæ ad ʒiv. misce.

Fiat mistura. Sumat ʒi. ter die ex ʒij. aquæ post cibos.

Recently Cacodylic Acid or its soda salt, Arsocodyle, has been greatly vaunted. (See page 45.)

Where the palate objects to any of the above preparations, a very elegant combination is the Citrate of Iron and Ammonia given in effervescence with Citric Acid.

R *Ferr. et Ammon. Cit. ℥ii.*
 Acid. Citric. ℥iii.
 Aqua ℥viij. misce.

St. coch. mag. c. coch. mag. Mist. Alkalim. ter die post cib.

The Alkaline Mixture contains Pot. Bicarb. ℥vi, Aqua ℥viii.

If headache follows the administration of iron, saline purgatives may enable the physician to continue its use, and he may give 5 grs. of the sulphate with 30 grs. of Sulphate of Magnesia in aerated water with advantage.

The treatment of anæmia should not, however, be confined to the official preparations of iron if these do not prove soon satisfactory. The natural iron waters of Buxton, Kissingen, Altwasser, Harrogate, &c., may be tried with advantage, and various organic salts of iron are believed by many to be more valuable than those in combination with the mineral or vegetable acids. Ferratin is absorbed in large quantities from the intestine, and may be given in $\frac{1}{2}$ oz. doses, but 15 to 30 grs. are sufficient for all purposes.

Ewald believes that iron is made assimilable by mixing a tea-spoonful of the tincture (perchloride) with 5 oz. water, previously blended with 1 oz. white of egg.

Stockman states that inorganic iron is more rapidly effective than organic iron, and the experience of Allbutt and most observers coincides with his. Notwithstanding the perpetual flood of these new organic iron preparations, the old official iron salts still hold their own.

Cod Liver Oil, Lactophosphates, Malt Extract, sea bathing, bracing air, and sometimes a short sea voyage and rest from mental work, often work wonders. Massage is also a powerful remedy in improving nutrition and influencing metabolism, and water charged with oxygen gas has found favour with some practitioners.

ANÆMIA (Pernicious).

Though much light has in recent years been thrown upon the pathology and diagnosis of this formidable affection by the brilliant researches of a host of observers, there is little advance in its treatment. In every case of supposed pernicious anæmia the hope of treatment lies chiefly in the discovery of some cause. Stockman believes that the anæmic state, no matter how pro-

duced, leads to multiple hæmorrhages, which give the disease its pernicious type. Many of the cases should be curable on this hypothesis if ordinary anæmic treatment was resorted to at an early stage. This hope is strengthened by the fact that such marked benefits follow the treatment of profound anæmias caused by duodenal and intestinal parasites, and other cases apparently identical clinically with pernicious anæmia where the condition has followed upon hæmorrhages from piles, gastric ulcers, and other affections.

The view generally held that the disease is a hæmolysis or blood destruction, produced by some toxic agent probably produced in the intestine by microbes, also leads to the hope that intestinal disinfection by improved methods may in the near future give decided results.

In cases where every other anæmic condition can be excluded, and the histological examination of the blood shows the typical characteristics, the prognosis is very bad. A fatal issue is the rule, but even here life may be prolonged, and in a small percentage of cases recovery may be witnessed. All the points mentioned in the previous pages under Anæmia must be attended to, thus change of environment and scene, and if possible, a residence in a bracing pure air, with freedom from worry and excitement, and opportunity for prolonged rest in the open air, are desirable. Farinaceous foods, with fresh vegetables, are to be greatly preferred to an animal diet. Stimulants must be sparingly used, but light red wines are admissible. In advanced cases, raw meat juice enemata and peptonised foods will be indicated. As for drugs, as a rule Iron is of little use, and often does harm, and cannot be tolerated. No agent has given such good results as Arsenic, and this drug must be pushed; it often is taken with difficulty, but the physician must persevere in its use. Many cases are recorded where great benefit has followed its administration, and not a few cases are recorded where permanent recovery has resulted. The Liquor should be given in 5 minim doses, increased to 15 minims, three times a day: and where the stomach is irritable the writer gives $\frac{1}{4}$ gr. Arseniate of Iron in a pill coated with Keratine. In one of the most unpromising cases great improvement followed in the writer's hands under 5 minim doses of Fowler's Solution (without lavender), given largely diluted with water, by the hypodermic method. This case was seen by Lorrain Smith, who found the total quantity of blood by his carbolic oxide method to be nearly doubled, though the number of the corpuscles had fallen greatly. When the patient passed from under observation he was almost convalescent, but he afterwards died.

Fowler's Solution can be given twice a day by the rectum in 5-10 min. doses dissolved in 4 dra. water and a few drops of laudanum.

A new remedy, Arsocodyle, or the Cacodylate of Soda, intro-

duced by Gautier, has created a deep interest. It contains 46·8 per cent. of arsenium—i.e., considerably more than twice the amount in Arseniate of Soda—and being an organic compound, it is claimed for it that it is more readily assimilated and much less irritating. The dose of Arseniate of Soda is $\frac{1}{16}$ gr., but the Cacodylate has been administered in doses of $1\frac{1}{2}$ grs. daily by hypodermic injection. 96 grs. dissolved in $3\frac{1}{2}$ oz. boiling distilled water and $\frac{1}{2}$ minim Carbolic Acid give a solution every 16 mins. of which contain $\frac{1}{2}$ gr. of the salt. This dose may be injected under the skin over the flank and epigastrium, and it is painless. The writer has used this solution, each dose of which can be obtained from the Parisian chemists in a hermetically-sealed glass capsule. It remains to be proven that there is any advantage in using a salt of arsenic which can be administered in forty times the dose of the older preparation. It is obviously necessary to demonstrate that the vast bulk of it does not pass out of the system as it entered. The drug is credited already with marvellous results in anæmia, phthisis, and skin diseases. If it proves only an unobjectionable method of administering arsenic hypodermically, an advance has been made. The above dose should not be exceeded in one day, and the injections should be suspended after eight or ten days for one week, and resumed for eight or ten days more. This dose has been given four or five times a day by the mouth, in solution or pill. It may be given by the rectum. Cacodylate of Iron is said to be more satisfactory still; 1 gr. may be given hypodermically in 30 mins. water daily, or up to 5 grs. daily by the mouth in cinnamon water or in pill.

Red Marrow, recommended by Fraser, has in a few cases given promising results, and is procurable in tabloids and capsules. Barrs administers this in the following way:—3 oz. of fresh bone marrow (as much red as possible) are made into a paste with 1 oz. port wine, 1 oz. glycerin, and 5 drs. gelatin. A little care is required in making the paste to keep the gelatin and the marrow sufficiently fluid for them to be thoroughly mixed. The gelatin should be soaked in enough water to soften it and then should be melted with the glycerin, the mixture being kept in a mortar previously made hot with boiling water, while in another heated mortar the marrow and wine are mixed. Then the contents of the two mortars should be thoroughly incorporated and allowed to set. This quantity may be taken in divided doses daily.

Salol, Beta-Naphthol, Salicylate of Bismuth, and other intestinal disinfectants have been recommended, and a few cases of recovery are recorded from these. They are given with the idea of checking the formation of the ptomaines in the bowel, upon whose presence the disease is supposed to depend. Lavage of the stomach and copious enemata are also recommended. Transfusion of healthy blood and of Saline Solution has been successfully tried, and the hypodermic injection of healthy blood serum appears to the writer to be worth a thorough trial. Massage has

been recommended. In the later stages, after improvement from any of the above, Iron may be given with advantage, though in the early stages it is so generally useless. As the weakness progresses and vomiting becomes marked, absolute rest in bed is essential, and gastric sedatives, with small and frequently-repeated doses of a good sparkling wine, and rectal feeding must be carried out.

ANEURISM.

The treatment of aneurisms depends upon their situation, magnitude, &c. Those outside the reach of the surgeon may be treated medically, and numerous proofs of the complete cure of abdominal and thoracic aneurisms have been recorded. The writer has dissected a thoracic aneurism which underwent complete solidification when under medical treatment some time previously, death having taken place as the result of phthisis after perfect cure of the tumour.

This is the treatment introduced by Valsalva and often associated with the name of Tufnell, the chief element in which is absolute and total rest for a period varying from three to six months. The patient is kept in bed and on no account permitted to sit up even for an instant, though he may be permitted to turn occasionally from side to side with slowness and deliberation, the object being by starvation to so reduce the amount of blood and the cardiac force as to greatly lessen the pressure upon the aneurismal wall, after which, by judicious feeding, the blood is to be slowly enriched with the view of causing the deposit of laminated fibrin in the sac. In plethoric subjects frequent small bleedings are necessary. The diet is to be carefully restricted. The total allowance of solid food is not to exceed 10 oz. daily, which may consist of well-cooked meat or fish and biscuit and liquid nourishment to the amount of 10 oz. of milk is allowed. Bellingham's dietary consists of bread and butter for breakfast, 2 oz., meat and bread for dinner, 2 oz. each; bread for supper, 2 oz.; with 2 oz. milk at each meal. As a rule stimulants are forbidden. The bowels are carefully regulated, occasional salines being given, and complete repose of body and mind as far as possible secured.

There are several drugs which have been believed to be of value in quieting the circulation and promoting coagulation. Chief amongst these is Iodide of Potassium, which must be given in full doses (10 to 30 grs. three times a day) for several weeks. Acetate of Lead has been used, but with apparently less benefit.

Aconite and Veratrum Viride have been employed to quiet the heart's action, but their administration can only be carried out for a short period without doing serious mischief. $\frac{1}{2}$ gr. doses of Chloride of Barium have been strongly recommended.

Iron may be used alternately with the Iodide treatment, as it is

an important matter to have the quality of the blood up to the standard, thereby favouring coagulation.

After a short time the heart's action settles down into complete regularity with a slower and weaker pulse, and, if everything prove favourable, coagulation of the blood in the sac takes place. Mercurial inunctions have proved useful in conjunction with Iodides in syphilitic aneurisms.

Chloride of Calcium has been administered by Professor Wright in doses of 15 to 30 grs. with the view of increasing the coagulability of the blood, so that fibrin may be deposited upon the sac's inner surface in layers which will ultimately seal up the lumen of the aneurism. One case of large abdominal aneurism treated by Dr. Wright and afterwards transferred by him to the care of the writer, was so markedly improved that he was able to leave hospital as practically cured the sac having become almost solid. Rest in the recumbent position is an essential element in the treatment.

Proto-nuclein is credited with a successful result in one case.

Where coagulation does not occur a variety of treatments have been tried and generally with fatal results. In the present state of our knowledge there cannot be said to be any of these lines of treatment specially worthy of recommendation —

1 Hypodermic Injection of Ergotin, with a view to cause contraction of the muscular coat of the aneurism and condensation of the tissues surrounding the sac.

2 The injection of coagulating liquids, chiefly the Perchloride of Iron, is highly dangerous, and has fallen into disuse.

Gelatin, Lancereaux and others recommend the injection of a Gelatin solution into the sac, and some successful cases have been reported.

Garngee advises that fibrin ferment be injected into the sac, and it has been suggested that lecithin should be injected into its outer coats.

3 Acupuncture by fine needles, or the introduction of foreign bodies into the sac to cause coagulation—as Horse Hair, Silver Wire, Watch Springs, Catgut, &c. The results have been most unsatisfactory, and nearly always fatal.

MacEwen introduces fine steel needles into the sac, and moves them about so that the points shall thoroughly scarify the wall of the sac on its inner aspect, thus producing a rough surface on which coagulation is likely to occur. When this has been done very thoroughly the needles are removed.

4 Galvanopuncture. This is carried out in a variety of ways, the best method being the insertion into the sac of two needles insulated with vulcanite except near to their points, the uncoated parts within the sac being so inserted as to be a considerable distance apart; the needles are then connected with the wires of a battery giving a low tension current, and the electric fluid permitted to flow between the needle points till coagulation of

the blood in the sac results, as evidenced by the alteration in the shape and pulsation of the tumour. Sometimes only the needle connected with one pole, either negative or positive, is inserted whilst the opposite pole is applied outside the sac or to the skin in its vicinity.

Some cases of cure have, undoubtedly, followed this method of treating internal aneurisms; but, upon the whole, the results are far from satisfactory, and fatal inflammation, sloughing, and hæmorrhage have followed.

The pain of internal aneurisms may be lessened by narcotics like Opium, Morphia, and Indian Hemp; and large doses of Iodide of Potassium sometimes give relief and render life bearable. 5 grs. of Antipyrine or 3 grs. of Antifebrin often relieve distress in a remarkable way without producing any bad consequences, and their administration may be continued for a long time.

Where the aneurism is upon any of the limbs within easy reach, there is good chance of a cure by some of the following methods — 1. Pressure upon the main trunk—digital or instrumental—or by flexion of the limb. 2. Rapid pressure under anæsthetics. 3. Local pressure upon the sac. 4. Ligature—proximal or distal, or both combined. 5. Extirpation. 6. Manipulation.

Ligature is the most satisfactory of all methods when possible. Aseptic surgery has eliminated the chief risks of the operation.

ANGIOLEUCITIS—See Lymphangitis.

ANGINA PECTORIS.

Treatment should be directed to the relief of attacks and to prevention of them.

During the attack, as soon as warning of its approach is felt, there is no remedy to compare with Nitrite of Amyl for rapidity of action and certainty of effect. The best way to use it is to break one of the silk enveloped fragile glass capsules, made by Martindale, and hold it under the patient's nose so that he may inhale the vapour. Each capsule contains from 2 to 10 minims. Those containing 5 minims will be found the best for all practical purposes. Generally the attack is immediately arrested after the first few deep inspirations. Other Nitrites may be employed, but the delay in their action, though but of a few minutes' duration, is a serious drawback to their use when the patient is struggling under the agony of an attack. Chloroform may be resorted to when Amyl fails or is not available. Where pain is severe and Amyl has not relieved it a hypodermic of Morphia should be given. If it be known that the patient is not the subject of advanced renal affection $\frac{1}{2}$ gr. may be injected, and he may receive 20 minims of Ether along with it. Oxygen inhalation often does much good and cannot do any harm, the gas being allowed to freely mix with the air a few inches from the patient's face. Other measures must not be omitted. All constriction about the chest

and neck must be removed, and the patient supported in the position which affords him the most relief. A rapid diffusible stimulant, like *Sal Volatile*, *Ether*, or *Brandy*, may be given—a large dose of *Spirit of Nitre* is the best—and warmth to the extremities may be tried. If there be a full stomach, or ineffectual attempts to vomit, a rapid emetic (30 grs. *Sulphate of Zinc*) will be useful.

The *Amyl* may be administered by the mouth. The following is a good formula for use in tea-spoonful doses in hot water :—

R. *Amyl Nit.* ℥j.
Spt. Vini Rectif. ℥xij.
Ol. Mentha Pip. Min. xxx.
Glycerin ad ℥iv. misce.

Where there is warning given to the patient a few minutes before the attack, *Nitroglycerin* in solution or tablet may be administered by a method to be mentioned presently.

In the mild attacks of pseudoangina similar treatment, though less energetic, should be resorted to. *Morphia* or *Chloroform* is hardly called for. The same remarks apply to tobacco angina. Often a tea-spoonful of *Sal Volatile*, with an equal dose of strong *Tincture of Ginger*, will be found to give relief when the vasomotor disturbance is brought on by flatulence, and a few drops of *Ol. M. Pip.* may be added.

In the intervals between the attacks, attention should be paid to everything that improves the health, especially to the exclusion of all worry and overpressure, or anxiety, alcohol, tobacco, and over-eating. Constant, mild, open-air exercise on the level is essential, with regular hours for food, rest, and sleep. If the angina is found to depend upon an organic lesion of the heart, suitable treatment should be directed to the affection, and *Digitals* and *Strychnine* are generally indicated, but these should be combined with fair doses of *Nitroglycerin* to correct the influence of the former drug upon the small vessels, and *Iodides*, when they are tolerated, should be administered in large doses at the same time. Full doses, 10-15 grs. *Iodide of Soda*, relieve pain in a marked manner and reduce tension. It is needless to say that the special cardiac lesion associated with the angina should receive its own specific treatment. If there be reason to suspect disease of the coats of the aorta and large vessels, *Iodides* are especially indicated, and may be continued for weeks or months, with short intermissions, in daily doses of 60 grs. In those patients where an attack of indigestion brings on the angina, remedies directed to correct this are clearly indicated, and often marked benefit follows the use of agents and food which relieve or prevent flatulence. Arsenic is often of value in those cases where the attacks are very infrequent and not severe. Full doses

(5 minims) of Fowler's Solution should be given 3 times a day after meals for many weeks or months.

The following is a well-tried formula in the average severe case of angina. —

R. *Sodii Iodidi* *℥iv.*
 Liquoris Fowleri *℥j.*
 Liquoris Trinitrini *Min. xx.*
 Aque Chloroformi ad ℥viii. *misce.*

Fiat mistura. Capiat ℥ss. ter in die post cibos.

Phosphorus has also a good reputation given in doses of $\frac{1}{10}$ – $\frac{1}{5}$ gr. Where the attacks come on often and severe, Nitrites must be resorted to in order to make life bearable, and a knowledge of the pharmacological action of the different members of this class is of the greatest use to the physician in dealing with these cases. Thus the rapidity with which Nitrite of Amyl relieves the spasm, by causing dilatation of the vessels, is the great drawback to its usefulness when we come to deal with the case in a more permanent way, as it is proven that its effects pass off as rapidly as they come on, and after a very few minutes the Amyl leaves no evidence of its action upon the vessels.

Nitroglycerin is much more lasting in its effects, whilst the action of Nitrite of Sodium is still more persistent. Consequently when the physician wishes to keep the abnormal high tension down for any length of time, he will select a substance more persistent in its action than Amyl. The writer has, however, found, by clinical experience, that much better results can be obtained by giving a very small and oft-repeated dose.

Thus the ordinary dose of Nitroglycerin is about $\frac{1}{100}$ – $\frac{1}{50}$ gr. (or 1–2 minims of the 1 per cent. solution) three times a day. Generally marked dilatation of the vessels and flushing of the face follow soon after each dose, but in an hour afterwards nothing remains but some headache, and hours before the next dose is due the tension in the vessels has assumed its usual abnormal height, and the next attack due comes on with certainty and in no way modified by the previous dose. His plan is to divide the daily amount (ordinarily given in 3 or 4 doses) into about 30 small doses, one to be taken every half-hour during the day. This is easily done by dividing the official tablets into fragments, or by getting tablets made containing $\frac{1}{1000}$ gr. each.

The patient does not, as a rule, object to slipping a fragment into his mouth every 15 or 30 minutes, especially as he soon learns that he avoids the severe headache and prevents the attacks taking place, and he soon learns to shorten or lengthen the interval as his experience of the premonitory symptoms enable him to judge of the probability of an attack. It is thus easy to obtain all the

benefits we wish from the drug without producing flushing of the face, or throbbing of the vessels of the neck, or headache.

Nitroglycerin acts as a nitrite, the nascent nitrous acid formed in the blood from its decomposition being more active than the nitrous acid of the nitrates.

Nitrates of Sodium and Potassium may be given in angina, and their dosage and administration can be carried out in the same way as suggested about Nitroglycerin. It is not convenient, however, to administer a dose of liquid medicine every 30 minutes to a patient going about the ordinary duties of life, and, hitherto, these remedies have been only given in solution, in doses varying from 1 to 4 grs. every 4 or 6 hours. A small lozenge, containing $\frac{1}{2}$ gr. of either salt, might be taken every half-hour with advantage.

Erythrol Tetranitrate, though too slow for the relief of the attacks, can be advantageously employed to keep down the pressure, and may be given in $\frac{1}{2}$ gr. tablets every two hours. Its action is much more prolonged than that of the nitrites.

Chloral, Bromides, Belladonna, and Aconite have been recommended to relieve pain and distress in angina, but their use is not to be recommended, especially Chloral from its dangerous depressant action upon the heart. Cocaine has been extolled by several, and Ethyl Bromide, Lobelia, Allyl, Hyosine, Cactus, Pyridin, Methylal, and many other agents have been recommended, but Nitrites or Nitroglycerin will generally meet all indications. Cold Lotions or Ice to the forehead, and Mustard and Turpentine to the chest, may give some relief to the paroxysm in the absence of Amyl.

The application of the continuous current, beginning with 15 and going up to 20 or even 25 Leclanche elements, with the negative pole on the nape of the neck and the positive pole placed over the lower half of the sternum, has been followed with very satisfactory results in some cases, and is always worth careful trial. Some prefer to only galvanize the sympathetic upon the left side.

ANTHRAX—See Malignant Pustulo.

ANKYLOSTOMIASIS.

The first thing is to kill and expel the parasite—*ankylostomum duodenale*. Though nearly all the ordinary anthelmintics have been successfully used, there is nothing so uniformly efficacious as Thymol. This must be given after a night's fasting in the form of a cachet, or capsule, or suspended powder, in doses of 15 to 30 grs., repeated every two hours for three or four times, followed by a brisk purge ten hours after the last dose if purgation has not already occurred.

Care is absolutely necessary that no oil, butter, alcohol or strong alkali be given till after purging, as these substances cause the insoluble Thymol to be absorbed, and death might

result. Eight or ten days after, if ova are found in the feces, the drug should be again administered. Santonin and Calomel are also efficacious. The very formidable anemia must be treated with Iron and Arsenic after the expulsion of the worm, and gastric symptoms and abdominal pain will require stomach sedatives combined with Morphia in small doses. The disease has been proved to be endemic all over the West Indies, British Guiana, South Africa, and many other regions. Ordinary cleanliness is the true prophylactic, since the larvæ are developed in the soil from eggs contained in human feces.

ANOSMIA.

When the loss of smell depends upon local causes, as polypæ, rhinitis, &c., if these receive prompt treatment the condition may disappear. Where the causes are centric the remedies indicated in the primary disease should be resorted to. In neurosthenic cases the induced current is valuable. The commonest cause in the writer's experience is influenza, and hypodermic injections of Strychnine, in conjunction with 2 gr. doses of Antipyrine and a little Arsenic, afford the best results. In all cases the condition of the pharynx should be looked to, Lennox Browne has seen anosmia cured by removing an elongated uvula.

ANUS, Fissure of.

This painful affection, when of long standing, must be dealt with by the knife. An incision may be made by drawing the knife across the middle of the fissure or small ulcer, dividing about a third of the fibres of the external sphincter, the bowels having been previously well opened, and the sphincter thoroughly dilated under an anæsthetic. The after-treatment is carried out upon the same principles as after operation for fistula.

Some surgeons deal with the fissure by forcible dilatation of the sphincter with the thumbs. Ball removes the small sentinel pile which guards the fissure or ulcer, and finds this is always sufficient.

Touching the ulcerated spot with the thermo-cautery, or, better still, with the galvano-cautery is often enough to effect a rapid cure. The motions must be kept soft by a well regulated diet, or by the administration of one large dose of Olive Oil daily, or a tea-spoonful of Sulphur or Castor Oil at bed-time. Dommer speaks highly of the effect of the Galvanic Current. One electrode is inserted above the sphincter, three to four sittings of five minutes each are sufficient to effect a cure in his hands.

If the case be not very chronic, and not much thickening of surrounding tissue has occurred, the application of a strong caustic to the fissure or ulcer may be followed by new action being set up, which may end in healing. Nitrate of Silver is the most painful. Chloride of Zinc (in stick) may be used; it is

difficult to manage. Pure Carbolic or Nitric Acid may be used with advantage for this purpose. Carbolic is less painful than Nitric Acid, and is to be preferred.

Ice should be kept in contact with the anus for some time afterwards and a morphia suppository be inserted, and a four per cent. Cocaine solution should be previously applied for some time to ensure complete anesthesia.

In ordinary cases of anal fissure the chief matter to see to is the agonising pain and pruritus after defecation, and a host of anodynes have been recommended and praised, the vast majority of which are utterly worthless. The following are a few formulæ which may be useful—Extract. Belladonnæ, 1 drachm, Ungt. Simplicis, 1 ounce. Or, Unguentum Galle cum Opio.

Or, Cocain. Hydrochlor., 30 grs.; Aquæ, 1 dr.; Lanolin, 1 oz., misce.

Extract. Krameriæ, 1 dr., Glycerini, 3 drs.; Lanolin, 1 oz., misce.

Bismuthi Carb., 1 dr.; Glycerini q. v. ut fiat pasta.

Glycerin Acid Tan., 2 oz.; Chloroformi, 1 dr., misce.

Iodoform, 1 dr.; Vaseline, 1 oz., misce.

Calomelanos, 1½ drs.; Ungt. Simp., 1 oz., misce.

Berger relieves pain and itching by inserting cotton wool soaked in the Liquor Calcis Chlorinatæ for an inch inside the anus.

This list having often failed with the writer, he was led to try Camum, and after repeated failure with the worthless Extract of the old B.P., he obtained surprising effects with an ointment, which is now the official Unguentum Conii. 10 grs. of the Ferrosulphate of Iron may be added in suitable cases, as recommended by Cripps.

The ointment appears to paralyse the endings of the motor nerves distributed to the fine muscular layer under the surface of the mucous membrane; the reflex twitchings of this layer keep up the perpetual pain and uneasiness in diseases of the rectum and anus associated with abrasions, ulcerations, or fissures. At the same time the sensory terminals are paralysed. After many trials the writer is satisfied that this will be found by far the best remedy for the pain of fissures and ulcerated hemorrhoids, and he has seen anal fissures heal under its use. It should be inserted well up into the bowel.

Recently excellent results have been obtained by Ichthyol, and cure has been reported by inserting it on a brush inside the sphincter. 15 per cent suppositories should give excellent results. The writer prescribes a combination of Ichthyol and Hemlock ointment, 1 to 4, and suppositories made of the same strength.

ANUS, Fistula of.

Though in the vast majority of cases of anal fistula a cure is not to be expected unless with the aid of the knife, nevertheless in recent cases, before resorting to incision, some faint hope of less severe measures being successful may be entertained. If there be

a free opening of the fistulous tract into the bowel at one end and through the skin at the other, it will be found waste of time trying to cause healing of the sinus without a free incision. The surgeon is justified in attempting a cure in *blind external* fistula by exciting new action in the sinus by passing a probe dipped in strong solution of Chloride of Zinc, or in pure Carbolic Acid. Nitrate of Silver causes so much pain and inflammation that it should not be used.

Tincture of Iodine injected by a fine syringe is sometimes followed by closure of the anus, but the writer strongly recommends the injection of the Compound Tincture of Benzoin, as being antiseptic and stimulating and free from danger, and not causing much pain. The galvano-cautery may be rapidly passed through the fistula. Any plan tried by the surgeon to cause healing of the sinus will end in failure if free drainage be not established. Mr. Cripps accomplishes this by inserting a little plug of gutta-percha, shaped by the fingers like a miniature mushroom. The stem is pushed into the fistula, and the flattened head kept in position by a little plaster; this soon widens the orifice, and permits free escape of pus. This line of treatment, though tedious and often very unsatisfactory, should be resorted to in those cases where the fistula is associated with some serious or fatal disease, as phthisis, diabetes, or hepatic cirrhosis.

When these methods fail the surgeon proceeds, after clearing out the bowel, to pass a probe-pointed director from the outer to the inner opening, the point of the director is then hooked down by the finger from within the bowel and made to project through the anus, and with one clean incision all the parts between the groove in the director and the mucous membrane are divided by a curved bistoury. Should there be a cul-de-sac running beneath the mucous membrane above the internal opening it had better be also laid open at the same time. If the internal opening is so far up that the point of the director cannot be brought down through the anus, the tissues may be divided by passing one blade of a fine probe-pointed pair of scissors into the groove on the director, and the other blade into the anus, and cutting the intervening tissues. Some surgeons go further than this and scrape the sinus thoroughly with a Volkmann's spoon, or dissect out the lining membrane of the sinus and any diseased tissue appearing in the wound. The wound heals from the bottom in a short time.

By inserting a flat piece of soft, smooth wood into the rectum, and passing a sharp-pointed bistoury along the groove in the director as it lies in the sinus with its point free in the rectum, the point of the bistoury, guided by the director, may be firmly sunk into the wood, and, both being withdrawn together, the intervening tissues are divided.

Those cases in which no internal opening is found are often sadly bungled in the treatment, the operator making an internal

opening which may be a long way off the tract of the fistula. The best method to pursue in such cases is to introduce the probe as far as it will go through the external opening, and dissect up the fistulous tract bit by bit, and follow out any side tracts in the same way.

Longo insists upon the entire excision of the fistulous structure and the union by first intention of the outer surfaces, unless there be hæmorrhoids, or when the internal opening is very high up.

The operative treatment of fistula in the *early* stages of phthisis is sound treatment, and the tract should be scraped or touched with the cautery.

The wound is packed with gauze or lint soaked in Iodoform Emulsion or smeared with Vaseline, and is allowed to granulate from the bottom. The bowels should not be allowed to act till the fourth or fifth day, and then only by a dose of Castor Oil.

ANUS, Imperforate.

The obliteration of the anal opening may be caused by adhesions of the epithelial layers around the anus, which can be easily remedied by tearing them open upon forcibly separating the nates. If there be no deficiency in the rectum, the bulging of the thin septum closing the anus being apparent, a free crucial incision will permit of the escape of the meconium, and subsequent dilatation with the finger will remedy the matter.

If, however, no bulging be evident, and there are signs that the lower portion of the rectum is absent, a dissection, beginning with an incision in the middle line behind the posterior margin of the anus, must be carried backwards and upwards till some bulging is observed. Sutures should connect the lower part of the newly discovered rectum to the margins of the skin wound on each side, and the bulging part be freely incised. It is of the greatest importance to carry the dissection far enough to permit suturing of the bowel to the skin if possible, thereby preventing cicatricial contraction or stricture, and for this purpose a portion of the cæcæx may be removed. Should the rectum not be reached by dissection from below, there is nothing open to the surgeon but to make an artificial anus, opening the bowel by Amussat's operation in the left loin, or in the left groin by Littré's method.

When the anus is absent and the rectum opens into the bladder, colotomy is the only course to pursue. Where the bowel opens into the urethra success may follow a perineal dissection like that just described. And where the lower end of the gut opens into the vagina the same procedure may be followed; the vaginal opening can be closed later on if still patent.

ANUS, Prolapse of—See Prolapsus Ani et Recti.

ANUS, Pruritus of.

If depending upon any local affection, this must be treated. If thread worms, fissures, ulcer of anus, or hæmorrhoids are

present suitable treatment must be at once undertaken, and, as a rule, the itching will disappear upon the removal of the cause. Many cases of pruritus do not depend upon any such irritation, being but the local expression of a well-marked neurosis, and, in these instances, Arsenic, Quinine, Phosphorus, Tonics, Salicylates, Antipyrine, or Antifebrin should be given. The general health and bowels must be closely looked after, and local treatment directed to allay the extreme irritability of the peripheral nerves. Allingham lays great stress upon the importance of plentiful ablution. He directs the patient to fill a gauze bag with bran, and after putting it into a very hot Sitz bath he should sit upon it with his buttocks widely separated for twenty minutes. The parts, after drying, should be freely dusted over with equal parts of Zinc Oxide, Boric Acid, and Starch, and at night a large pad of cotton wool dusted with the powder should be worn by means of a T bandage.

There is no better remedy than Conium Ointment. This can be made of double the B.P. strength by the author's formula, and he has generally found it to act very rapidly and effectually. It may be combined with Tar, Lead, Camphor, Phenol, or other local astringent.

Cocaine gives short relief, and Morphia suppositories—with or without Belladonna—though they may relieve the itching for a time, often appear to aggravate it.

The method of inserting a small plug of wool saturated with the Liq. Calc. Chlorinata may prove effectual.

An ointment, containing Creosote or Carbolic Acid, 1 drachm, Lard, 2 oz., Camphor, 1 drachm, is a safe and often effectual remedy. The various formulæ mentioned under anal fissure may be also tried. Where ointments do not afford relief, the writer has seen marked benefit from dusting very freely the parts in the neighbourhood of the anus with Carbonate of Bismuth. Lotions are seldom successful. When ointments fail, the following may be tried. —Glycerin, Boracic, 1 oz.; Aquæ Menth. Pip. ad 20 oz., misc. Or Chloral Hydrat., 2 drs.; Aquæ Rosæ, 10 oz., misc. Or free sponging with a warm solution of Borax, or a solution (20 grs. to 1 oz.) of Nitrate of Silver may be painted on.

Friction and scratching should be particularly avoided.

The constant current, 10 Leclanche cells, may give marked relief, and at bed-time a small enema of 3 to 5 oz. cold water often acts like magic.

In women the condition may be an extension of the vulvar affection.

Sir W. Banks has recently drawn attention to the value of the actual cautery in obstinate pruritus of the anus. He uses the large bulbous-headed cautery usually found in Paquehn's case, and frizzles the skin for an inch and a half round the anal orifice, the application being made under chloroform in the lithotomy position. (See also under Pruritus.)

APHASIA.

The treatment of this condition will, for the most part, be included in the treatment of the hemiplegia, with which the defect of speech is usually associated. Absolute rest of body and mind, with very restricted animal diet and mild purgation, associated with treatment directed to the original lesion causing the hemiplegia, will be all that the physician can do. Should all traces of the hemiplegia pass away, and there be evidence that the patient, though aphasic, retains his mental faculties still unimpaired, he may be taught to speak, and instances are recorded where recovery has been in this manner made complete.

APHONIA.

Depends upon causes which prevent the vocal cords meeting, hence its treatment may in one case be the treatment of paralysis of the adductors, or of any organic lesion as tumour, ulceration, ankylosis of cartilages, &c. Generally, however, complete aphonia comes under the eye of the physician as a manifestation of hysteria, and its cure is rapid and satisfactory. A strong induced current is the remedy for this affection. One wire of the battery is attached to a flat electrode, which is made to rest upon the outer surface of the larynx, whilst the other wire is attached to a lingual electrode mounted on a handle, containing a small contact-breaker. This electrode is inserted into the space between the cords, and the current turned on by pressing the button in the handle so as to produce a painful and a severe shock. At the same moment the patient should be commanded to pronounce some word which she frequently accomplishes in a loud cry. Occasionally the application of the shock must be repeated. The continuous current is useless, and so also is a weak induced current. Sometimes the passing of a smart induced or interrupted current across the larynx, by applying a pole to each side of the external surface of the larynx, is enough to restore voice. (See under Hysteria.)

The writer has witnessed the successful treatment of hysterical aphonia by intoxicating doses of Alcohol—a most objectionable and unjustifiable proceeding. Atropine and Belladonna, pushed to the extent of producing their physiological actions, have been employed, but Electricity fulfils every indication. Strong solutions of Nitrate of Silver, 1 dr. to 1 oz., or of Perchloride of Iron, 2 drs. to 1 oz. have been applied with a brush to the larynx with rapid improvement. Hunt recommends the training and systematic exercise of the vocal cords by singing the vowels and numerals.

For the treatment of Hoarseness, see Laryngitis.

APHTHÆ OR APHTHOUS STOMATITIS.

The physician should see to the absolute cleanliness of all bottles or vessels used by hand-fed children. The local application of the tincture of Borax is the best remedy. A little placed on the tongue or brushed upon the lining membrane of the mouth every hour or two is fatal to the life of the *odium albicans*, upon whose

presence the affection depends, and a speedy cure generally results. Borax and Honey may be used, or a small quantity of a powder consisting of Powdered Borax and Sugar may be dusted upon the aphthous ulcers frequently, or Boric Acid or its glycerum may be used instead of borax. A weak solution of Chlorate of Potassium (1 in 50) is also very effectual.

As there is often so much pain present that feeding is very difficult, a spray of Carbolic Acid (1 in 100) may give great relief, or 2 per cent. of the acid may be added to the Glycerin of Borax.

Should the ulcers be deep or show any signs of spreading, as they may do in weak, bottle-fed children, they should be touched with Nitrate of Silver or Nitric Acid, or a strong solution of Sulphate of Copper or Alum. If, notwithstanding this treatment, the aphthæ continue to increase, the food of the infant should be changed or a healthy wet-nurse obtained. An occasional dose of Grey Powder will do good, and if there be much prostration small quantities of Brandy may be given, or Quinine may be indicated with minute doses of Iron should diarrhœa be present. A few grains of Boracic Acid added to each pint of milk is most valuable.

For the treatment of the other different varieties of Stomatitis, see under Stomatitis.

APOPLEXY.

The treatment will depend upon the nature of the lesion causing the seizure, in the absence of information it may be wise to regard every case as caused by cerebral hæmorrhage. Rest and absolute quiet are essential, and it is a serious mistake to carry the unconscious patient up or down stairs, or to any distance. He should be placed in bed in the room in which his attack began, when this is possible. His clothes should be removed with slowness and care, a nurse or assistant taking charge of his head while this is being done. Placed upon his back upon a hard mattress, his head and shoulders should be elevated and all constriction about the neck removed, and his face turned to one side so that the tongue should not fall directly backwards and impede the breathing, and so that fluid secretions may be allowed to flow out of the mouth.

A smart purge should be given, especially if it can be known that constipation is present, and 5 grs. of Calomel and 1 minim of Croton Oil placed upon the tongue will find their way into the stomach. Stimulants always given upon these occasions should be avoided, and no nourishment should be administered till the ability to swallow returns. If the pulse be bounding and the carotids throbbing, and signs of high arterial tension be evident, the physician should not hesitate to bleed at once. By incising the vein in the arm and allowing a full stream to flow from a large opening further cerebral hæmorrhage will be prevented. Leeching or Cupping is worse than useless.

To prevent extension of the hæmorrhage astringents like Ergot, Tannin, Lead, &c. are absolutely useless, but undoubtedly good can be done by the hypodermic injection of Chloride of Calcium, which rapidly raises the coagulability of the blood. 15 grs. may be injected dissolved in water. Such a measure would be injurious if the case was one of thrombosis or embolism, as would also be the following.—Compression or even ligature of the carotid on the side of the lesion. This has been recommended by Horsley and others, and even suggested as a prophylactic in threatening cases. Trephining has been resorted to successfully in a few cases.

If the head is hot, ice should be applied to the forehead, and no harm can be done by Mustard to the back of the neck. Shaking of the patient and attempts to arouse him by shouting or flagellation are unpardonable, and the physician must abstain from further active treatment and await events. The lips may be moistened with a little water or Glycerin of Borax, and if the period of unconsciousness be prolonged, enemata of eggs and milk may be given, or better still, the patient should be fed through the nasal tube. It is wise to abstain from all animal food for a considerable time after swallowing power returns.

Sometimes the physician may chance to see a patient whose premonitory headache and drowsiness may warn him of an approaching attack, especially if an attack of apoplexy or hemiplegia, or previous symptoms of softening had occurred in the same case, by brisk purging or blood-letting, and the treatment just mentioned, the attack may be warded off.

After consciousness returns the most rigid silence and repose must be maintained, and any reaction, as shown by flushing of the face, or headache and feverishness, must be met by ice to the head and a diaphoretic, small doses of Aconite, combined with Bromide of Potassium, being useful. At a later stage the Bromide, combined with Iodide, may facilitate the absorption of extravasated blood and small doses of Arsenic may be given along with these remedies.

If there be evidence of syphilitic disease of the cerebral arteries, Mercurial Ointment should be rubbed in at once and continued till a decided impression is made on the system; afterwards large doses of Iodide of Potassium should be given.

APPENDICITIS—See Perityphlitis.

ARTHRITIS DEFORMANS—See Rheumatic Arthritis.

ASCARIS LUMBRICOIDES.

The remedy for the Round Worm is Santonin. By far the best way is to mix the powder in Castor Oil, and give it in doses of 2 grs. to a child 3 years old and upwards; rarely will adults require more than 5 grs. If purgation does not follow in 6 or 8 hours, a Sine Cathartic or Senna may be given. In the case of children who will not take Castor Oil, Santonin may be mixed with butter

and spread upon a slice of bread, and since it is always best to give a purgative along with it, 2 or 3 grs. of Calomel may be sprinkled upon the butter. The writer has found that Syrup of Senna makes a splendid vehicle, and almost every child will take the mixture. If purging does not follow, more Syrup may be given in 6 or 8 hours. Santonin is also given in a powder, mixed with Scammony or Rhubarb or Jalap—an unnecessary and nauseous combination.

Yellow vision and orange-red discolouration of the urine very often result, but soon pass off. It should be always borne in mind that Santonin in large doses is a dangerous drug, liable to produce cerebral symptoms, and the B.P. Lozenges should not be left in the way of young children. Castor Oil certainly minimises the danger of untoward effects. The writer has never once seen any untoward effects in several thousands of cases in the large practice of a children's hospital, where the drug was always prescribed with Castor Oil.

Sulphur, Spigelia, Turpentine, Male Fern, Kamala, and Kousso, and various Indian vermicides are recommended, but Santonin never fails. It may be given for 2 or 3 days in succession. Manson states that it is a good plan to give $\frac{1}{2}$ -4 grs. (according to age) for three successive nights at bed-time, and on the mornings following the first and third doses to exhibit a dose of Castor Oil. The preventive treatment consists in purification of the water consumed and the cooking of all salads, &c.

ASCARIS MYSTAX,

A smaller round worm, is destroyed as readily as the large round is by Santonin, given in the same manner and dose.

ASCOITES.

The treatment of the different affections which cause ascites will be mentioned under the heading of each. For convenience the following survey is here given:—

1. If the ascites be caused by the presence of malignant or other tumours upon the trunk of the vena porta outside the liver, obstructing the flow of blood through the vein, little can be expected except palliative treatment.

2. If the obstruction be *within* the liver as in cirrhosis (by far the most common cause), abstinence from all stimulants and irregular living, the free use of Saline Cathartics, regularity of diet, with open-air exercise and change of climate or scene, and a course of mineral acids (Nitro-hydrochloric), afterwards followed by Iodides and sea-bathing, may effect removal of the fluid if the cirrhotic change has not proceeded too far. (See Liver Cirrhosis.)

The same lines, in the main, may be pursued where perihepatitis is the cause of the ascites.

Where the ascites results from the pressure of syphilitic gummata

in the liver substance or in the transverse fissure, Mercurial treatment, followed by very large doses of Iodides, is indicated.

Where amyloid disease in a similar way is producing the accumulation, the removal of the cause of the amyloid affection (prolonged suppuration or syphilis) should be attempted. Cancerous masses inside the liver may cause ascites, which can only be reduced by tapping.

3 Obstruction of the vena cava inferior, or of the hepatic vein, is generally outside the range of curative treatment.

4 Ascites may be a part of the general dropsy of Bright's disease, when purgatives, diuretics, and hot-air baths will be indicated. (See Bright's Disease.)

5 Chronic peritonitis, secondary to some primary affection, as rupture of a cyst, ulcers in the bowel or stomach, tubercle or cancer must be treated by attention to the underlying cause, or, failing this, by tapping. In tubercular cases, laparotomy has given surprising results; and recently the withdrawal of some of the fluid and the injection of sterilised air and oxygen has been advocated. Injection of emulsion of Iodoform has been also tried.

6 Diseases of the heart causing serious interference with the circulation in the large veins, leading to ascites, must be combated by remedies which aid compensation and strengthen the muscular power of the ventricles and auricles, as Digitalis, Broom, Strophanthus, &c., assisted by purgatives and diuretics.

7 When changes in the lung lead to embarrassed circulation and ascites, little can be done except in the way of palliation. Accumulation of a large amount of pleural fluid can be easily removed by tapping.

In ascites from any of the above-mentioned causes which fails to disappear after our attempts to strike at the primary affection, we may proceed to treat the ascites itself, regarding it as a local dropsy and endeavour to produce its absorption —

1 By acting upon the local absorbents with rubefacients or counter-irritants, as Iodine or Small Blisters (a most unsatisfactory method), or by rubbing in the Lin. Pot. Iod. cum Sapone.

2 By Purgatives—chiefly Salines, Elaterium, Jalap, or Croton Oil.

3 By Diuretics—like Digitalis, Copaisba, Asparagin, Broom, Gum-Resin, or Calomel.

4 By Diaphoretics—as Hot-air Baths, Acetates, &c.

5 By Absorbents (Antipyrine, Iodide of Potassium, &c.), which stimulate the lymphatics and tend to absorb effused products.

6 By tapping.

This latter method of treating ascites has for its object two very distinct aims :—1. To give relief where the amount of the accumulation is so great as to cause serious discomfort. 2. To cure the ascites where this is not depending upon a fatal cause. Thus life may be prolonged by tapping in ascites caused by cancer, and the

ascites may be cured completely by repeated tapplings in early cirrhosis of the liver, as proved by Roberts and others, and witnessed by the writer upon several occasions.

The operation is a very simple one, and may be performed with an ordinary trochar and canula. After evacuation of the contents of the bladder, a broad binder is passed round the abdomen and the ends grasped by two assistants who keep up pressure by pulling upon the ends of the bandage, as the fluid flows. By making a hole in the bandage opposite the middle line and half way between the umbilicus and pubes, the site of puncture is exposed, and with a good sharp plunge the canula and trochar are driven through the abdominal walls precisely in the middle line and half way between the pubes and umbilicus, the surgeon having satisfied himself previously that absolute dulness was present in this region. Upon the withdrawal of the trochar, fluid will continue to run till the peritoneal cavity is emptied, and the pressure of the bandage will prevent syncope or weakness during the operation and after, as it should be tightly fastened and left on after the canula is withdrawn and the puncture closed with a little plaster or collodion, or covered with lint greased with carbolio oil.

The patient, if weak, may be in bed in the recumbent posture; usually it is more satisfactory to have him seated in an arm-chair with the pail for the reception of the fluid between his knees.

The aspirator may be used, but it is wholly unnecessary. Southey's tube, which is a fine trochar and canula with several feet of rubber tubing attached, is a most desirable instrument for tapping the abdomen. It may be left *in situ* for many hours, and by dropping the free end of the tubing into the pail under the surface of the liquid, the fluid contents of the peritoneal sac can be safely, slowly, and painlessly syphoned away without danger of syncope, hæmorrhage, or peritonitis.

After the removal of the fluid, by the judicious use of iodine with moderate pressure externally, and purgatives and diuretics internally, the reaccumulation of the fluid may, in some instances, be prevented.

Morison recommends an operation whereby permanent cure can be accomplished by suturing the liver and omentum to the abdominal wall, and several successes have been recorded. In one case which died after an operation for the relief of a ventral hernia, resulting from this method of treating cirrhosis, the liver, spleen, intestines and omentum were found attached to the abdominal wall by adhesions, some of which contained vessels as large as the radial artery. The radical operation had been successfully performed two years previously for ascites caused by the cirrhotic liver. Several successes have been recently published by suture of the omentum to the abdominal wall and the operation promises well in the treatment of otherwise hopeless cases.

Wisen suffered from ascites for 10 years, caused by congenital affection and hydatid of the liver, and succeeded in drying up ascites by a diet containing as little fluid as possible. 12 ozs. fluid with his dry diet always dispelled the accumulation, and relieved all the distressing symptoms in a few days. By way of experiment, he brought on his ascites in 10 days, and removed it in 10 days' treatment of dry diet.

APHYXIA.

Under the different affections giving rise to this symptom, the appropriate treatment of each is mentioned as under Drowning, Passages, Foreign bodies in, Laryngitis, Glossitis, Bronchitis, Poisoning by Chloroform, &c., &c.

Asphyxia in new-born infants is best met by the instant removal of mucus from the mouth and throat, the dashing of cold and dry ether alternately upon the face and thorax, the inflation of the lungs with air by bellows, by a large catheter, or by the mouth of a physician, and the establishment of artificial respiration by Foster's method as detailed under Drowning, or a strong induced current may be used. Where the upper air passages are blocked, placing the child on its back on a table, with the head hanging over the edge, and passing a catheter through the glottis till the point is $3\frac{1}{2}$ inches from the teeth, and blowing air through the catheter all the mucus or blood above this point may be forced into the mouth.

Laborde's method consists in seizing the tongue with forceps, and making rhythmic tractions upon it at the rate of 15-20 times minute. It is a most valuable method.

In suicidal hanging it is hardly necessary to state that the neck should be cut down immediately, and after removal of all obstructions from the neck, artificial respiration should be commenced and kept up for a long period, and opening of the jugular vein may be tried. Where these measures fail the trachea should be opened, and the lungs inflated through the opening with air or oxygen.

In asphyxia in heart and lung diseases where death is threatening from engorgement of the right side of the heart, blood-letting should be promptly resorted to, followed up by saline purgatives and the inhalation of oxygen, or the internal administration of drop doses of Richardson's Ozonic Ether in distilled water as recommended by Ransome.

For the local asphyxia of Raynaud's disease strong constant currents, with the positive pole over the lowest cervical vertebra and the negative on the lumbar region or the immersion of the affected limb in a salt foot bath containing one electrode, whilst the other is placed higher up, will give the best means of warding off gangrene.

ASTHENOPIA.

If the weakness of sight depends upon hypermetropia through exhaustion of the over-worked ciliary muscle in attempting to remedy the focus of parallel rays falling behind the retina, absolute rest to the eyes must be insisted upon for a time. Such measures as improve the general health should be prescribed, and the effort at accommodation should be made easy by the use of properly selected convex lenses.

The treatment of asthenopia caused by insufficiency or weakness of the recti will consist in the correction of any errors of refraction which may be present, after which the defective power of the muscles can be overcome by suitable prisms and systematic exercise of the weakened muscles. Pilocarpine or Eserine solutions may be occasionally instilled with the view of stimulating the ciliary muscle.

Where the asthenopia is retinal, or depending upon some exhaustion of the general nervous system, as may be seen after recovery from serious illness or in neurasthenia, the eyes should, as far as possible, be rested from all close work, and, if there be any photophobia, light should be modified by the use of smoked glasses. Every means of restoring the general health should be attended to, and the treatment recommended for amaurosis be used, *i.e.*, hypodermic injection of Strychnine, with Iron and Quinine internally at the same time, or large doses of Easton's Syrup may be prescribed. The spasms of accommodation may be relieved by Cocaine or Atropine occasionally dropped into the eye.

ASTIGMATISM

Can only be remedied by the use of cylindrical lenses which correct the unequal refraction of entering rays in the two chief meridians. There is extreme difficulty in correcting irregular astigmatism. The serious nerve symptoms which follow eye-strain will often demand immediate correction by means of suitable glasses, and many patients obtain immunity from migraine and other forms of severe headache for long periods after being fitted with proper cylinders.

ASTHMA.

Treatment will resolve itself into the management of the case with a view to *prevention* of the attacks, and, secondly, to the exhibition of remedies with a view to affording *relief* in the attack of bronchial spasm. These lines will often necessarily overlap each other, as the remedies which will effectually prevent the actual attacks will sometimes give speedy relief when the paroxysm is already established.

The preventive treatment of asthma will resolve itself into a careful examination of the cause or causes at work in bringing on an attack. The avoidance of such causes sometimes settles easily

the entire problem of treatment, as may be seen in those cases where the attacks are brought on by the inhalation of light dust from feathers, and by breathing air charged with various irritating vapours and emanations.

Atmospheric or climatic cause is very striking in many instances, and it is remarkable how asthmatics can live in perfect freedom in the close air of large cities, whilst a journey into the pure, clear atmosphere of the open country or sea-shore at once brings on a series of severe and distressing attacks, only to be successfully treated by a return to the smoky city air. In comparatively rare cases, however, the converse is true, and the treatment to be immediately adopted is to send the patient back to the region in which he has enjoyed immunity from attack. Where the disease has originated in a damp climate the patient should be sent to a dry one, and if at the sea-shore, an inland spot should be selected in the same empiric way. If asthma be contracted in a low-lying or cold situation, the physician may be led to advise his removal to an elevated or warm atmosphere.

The diet should be most carefully regulated, and excess avoided. Animal food should be sparingly used. Some patients may be cured by a purely vegetarian regimen.

Food should be taken at regular intervals, and the non-constrictor plan of one enormous meal in the evening of the day must be given up. As a rule, liquids should be sparingly used and stimulants restricted, especially malt liquors. Now and then cases may be rarely met with in which excess of starch or vegetables cause aggravation of the symptoms—a free fish diet will then be indicated. The bowels must never be allowed to get constipated.

In hereditary cases prolonged gymnastic exercises, and, as far as possible, everything effecting a change in the patient's environment must be thought of, and excessive coddling must be avoided.

Where the affection is depending upon bronchial inflammation, the judicious treatment of this by expectorant remedies will be the obvious preventive measure. Where Bright's disease, joint troubles of a rheumatic kind, gout and skin diseases, and morbid states of the blood, caused by deficient elimination of excrementitious products by the excretories, are the cause of the attacks, much may be done to prevent their recurrence by attention to these morbid conditions.

In some cases the presence of asthma has been found to depend upon adenoids, nasal polyp, or hypertrophy of the turbinated bones, the paroxysms never returning after the removal of the local trouble.

For the prevention of attacks and as cures for the neurotic condition lying behind the symptoms of the disease, a host of drugs have been vaunted; many of these will be mentioned as useful in the relief of the paroxysm. There are two agents which, however, can be depended upon as a routine treatment of asthma between the attacks, and which if persisted in will be often found

not only to keep the malady in check, but which hold out in a considerable number of cases a fair hope of a lasting benefit. These drugs are Arsenic and Iodide of Potassium or Sodium. They may be combined and taken together for periods of six or eight weeks at a time and then suspended for fourteen days.

The following is a good formula. —

R. *Sodii Iodidi* *℥iij.*
 Liquor. Fowleri *℥iiss.* " "
 Vini Ipecacuanhae *℥vj.*
 Tr. Belladonnae *℥iij.*
 Aqua Chloroformi ad *℥vi.* *misce.*

℞. mist. Cpt. ℥j bis in die p.c. ex aqua.

After a time the Arsenic and Iodides may be given in alternating courses, and Iron or Strychnine may be added, or other drugs indicated by the presence of the various symptoms which may arise, can be added from time to time. A course of natural Arsenical water, as the Mount Doré or Bourboule, may be beneficial.

The remedies used in the treatment of the attacks are legion, and, unfortunately, the physician is driven to try one drug after another; the means which afford speedy relief to one patient may aggravate the paroxysm in the next; nevertheless, there are certain remedies about whose general value there is little room for doubt.

Inhalations.—The urgent distress of the paroxysm calls for a remedy which will be quick in its action, hence those which directly reach the bronchial surface are indicated. The oldest, and perhaps the most prized, of this class of medicines is the Nitre Paper, made by soaking thick blotting paper in a warm solution of 2 oz. of Nitrate of Potash in a tumblerful of water. After drying, this paper should be burned rapidly and in large quantity in the apartment of the patient, and, as the suffocating air of the room, with its nitrous fumes and smoke, becomes unbearable to his attendants, the asthmatic begins to breathe with ease and comfort. It is a common mistake to burn too little of the paper, and to have the solution too dilute. Huggins' Ozone Paper is prepared by adding Iodide of Potassium to the Nitre solution, and Chlorate may be also added as suggested by Thorowgood, to increase the activity of the combustion.

Stramonium, and various drugs of the same class, are burned in a somewhat similar way, this being the basis of most of the patent asthma cures. The formula recommended by Sir J. Sawyer answers well. It is made by mixing together 2 oz. of coarsely powdered Stramonium leaves with 1 oz. of powdered Anise fruit and 1 oz. of powdered Nitrate of Potash. A little of this placed upon a plate and ignited with a match gives off dense fumes, which generally afford prompt relief. *Mullein (Verbascum*

Asthus) is sometimes added, and a minute quantity of Arsenic is a valuable addition; powdered Tea enters into most of the good asthma powders, and Tobacco also is sometimes added. The Brompton Hospital formula is—Anise, 1; Nitre, 1; Stramonium leaves, 2; Tobacco, 5 grs. to the oz.

The inhalation of Pyridin is often of great value; it is one of the products formed during the combustion of the Stramonium powder. A tea-spoonful poured upon a plate soon permeates the air of the apartment with an intensely disagreeable and penetrating odour. It is highly recommended by See, but patients soon turn against its unpleasant and nauseating smell.

Instead of burning Stramonium and inhaling the fumes, it is a common practice to smoke it in a pipe, and there is no doubt that in this way many asthmatics get relief. A little Nitre may be added to the chopped leaves, and Belladonna is sometimes mixed with them.

Datura Tatula, a drug of the same order, is often more satisfactory, and its action is very decided. It is smoked like the Stramonium. Both these drugs can be obtained in the cigarette form, and when Arsenic is added a very valuable remedy is obtained which generally gives more than mere temporary relief. 1 gr. of Arsenite of Potassium is enough for each.

Lobelia is sometimes mixed with the Stramonium before smoking and it is a constituent in many asthma cigarettes.

Though considerable and often instant relief follows the use of these fumigating preparations, there is no doubt that they are generally much abused and much too frequently resorted to.

Morphia.—In very bad attacks, where the patient cannot swallow, and where he can only inhale with great difficulty, the best treatment is to give hypodermically $\frac{1}{4}$ to $\frac{1}{2}$ of a grain of Morphia, with two minims of the B.P. Liquor Atropinae. Yeo states that he knows of no remedy so generally efficacious in cutting short a severe attack of asthma as Morphia administered hypodermically, and Goodhart places it first on the list of palliatives. Uræmia is an absolute barrier to its use.

Disulfof, at the beginning of an attack, paints the nostrils as high up as possible with 5 per cent. Cocaine solution, and sprays this over the mouth, throat, and nose for a few minutes, and if the cræcæ does not speedily yield, he injects the drug hypodermically.

Nitrite of Amyl is sometimes of great value in relieving the spasm, and it may be employed in the form of capsules (5 minims each). The vapour acts often very promptly, but its effect is exceedingly evanescent.

Chloroform vapour is a favourite remedy with some. Its action seldom fails, but it is not a remedy to be often repeated, and may prove fatal where there are cardiac complications. Ether, though safer, is more disagreeable, slower, and less certain.

Iodide of Ethyl is strongly recommended by Thorowgood, who advises the inhalation of the vapour of 10 minims three or

four times a day. It can be had in glass capsules like amyl nitrite, and, in addition to its antispasmodic power, it is a valuable expectorant. Martindale's capsules, each containing 10 minims of Chloroform and 5 of Iodide of Ethyl, are very safe and effective, and are highly recommended by Williams as being capable of safe administration by the patient or by nurses; they relieve the spasm and quiet the cough which accompanies it.

Ipecacuanha wine, in the form of fine spray, is of value in asthma where there is much bronchial inflammation.

Steam inhalation alone, or mixed with Terebene, Menthol, Oil of Eucalyptus, Cajuput, Creosote, or Friar's Balsam, is sometimes very soothing and grateful.

Chloral will cut short the attack if given early, in 30 gr. dose, and Williams strongly recommends it to be taken at bed-time, or even every four hours, for several days if bad spasms are threatening.

Williams' plan is to give Stramonium, Belladonna, or Hyocyamus in the form of succus or tincture, combined with the Iodide of Potassium, to be taken during the day, and to administer a pill of extract of Belladonna or of Stramonium ($\frac{1}{2}$ grain) during the night attacks.

Lobelia by the mouth is much praised in asthma; it is, however, a serious depressant to the heart in large doses. 20 minims doses of the ethereal tincture may be tried every four hours. It will give relief if the physician have courage to push it.

Nitrites of Soda and Potash are serviceable in asthma, and if given in small and often repeated doses will prevent paroxysms in those cases associated with high tension. Their effects are much more lasting than those obtained by amyl or glonoin, and they afford often speedy relief when administered during the paroxysm. Fraser has found that the smoke of nearly all the fumigating powders and papers contains nitrites in notable quantities, and he thus explains their value in relieving the spasm of the bronchial muscle, which is the pathological factor in asthma.

Nitroglycerin will give good results in some cases, and if administered in the minute doses every hour, as described upon page 50, excellent effects will be secured in bad cases.

Apomorphine in doses of $\frac{1}{4}$ gr., where there is much bronchial irritation, may be tried, and $\frac{1}{8}$ gr. hypodermically will sometimes cut short the paroxysm when internal remedies fail.

Antipyrine in full doses, 30 grs., has been given with success at the beginning of an attack, and in small doses, 5 grs., three times daily between the attacks; it prevents their occurrence or lessens their severity.

Caffeine in doses of 3 to 5 grs. has been productive of good in the treatment of asthma. Where there is cardiac failure, it is a very safe and efficacious drug, and much more satisfactory than Digitalis and Sparteine.

Alum sometimes relieves spasm of a severe nature, and it is

recommended to give 10-15 grs. dry by placing it upon the tongue. In full doses it is liable to excite nausea.

Gelsemium, Grindelia, and Euphorbium Pilulifera have been tried and found successful in some cases; the two last may be given every four or six hours in doses of 1 gr. of the pilular extract; 10 minims of the tincture of Gelsemium may be administered four times a day.

Oxygen or Compressed Air, and Rarefied Air, by means of the pneumatic chamber, in inhalation, have their advocates.

Hyoscine, hypodermically, in doses of $\frac{1}{100}$ — $\frac{1}{50}$ gr., will cut short the paroxysms, and

Cannabis Indica, by the mouth, acts in the same way; and Pilocarpine, subcutaneously, has its advocates; but this latter drug acts best where there is no secretion, whilst Hyoscine and Belladonna or Atropine are indicated when there is much secretion.

Strychnine has proved useful where there is exhaustion of the respiratory centre. Its use is, however, seldom indicated, and it may increase the distress. It has been recommended by Mays, who gives it hypodermically with Atropine. Quinine is open to the same objection.

Bromide of Potassium may do some good by relieving spasm, but its action is too slow to be of much value.

Paraldehyde has recently been praised as a good respiratory sedative, it is absolutely safe.

Tobacco will give marked relief (acting like Stramonium when smoked), but only to those who are strangers to its use.

Suprarenal Capsule.—Recently Solis-Cohen has published glowing reports upon the success of this powerful agent. By the mouth, 5 grs. of the gland substance may be given every two or three hours.

Blistering over the pneumo-gastrics with cantharides or strong iodine liniment may be tried in conjunction with any of the above treatments, and Galvanism (continuous or induced current) applied cautiously to the same region has been advocated. Yeo recommends a strong induced electric current applied to the throat in the situation of the great nerve trunks, the poles being placed below the angles of the jaw in front of the sterno-mastoid. Compression of the pneumo-gastric nerve, by the finger, has given good results.

Ice applied to the same region has proved successful in the hands of Sangre; it can be readily applied by enveloping pieces of ice in a handkerchief and keeping them in contact with the skin over the pneumo-gastrics.

Antispasmodics, like Asafoetida or Ammoniacum, and the entire range of expectorants from Antimony to Sulphur, have been tried with very varying success.

Cardiac and renal asthmas will be relieved by the use of the drugs mentioned under *Heart and Bright's Diseases*.

ATAXIA—See Locomotor Ataxia.

ATHETOSIS.

The slow, irregular, deliberate movements generally seen in the arm or leg, and constituting the diseased condition known as athetosis, is not beyond the reach of treatment. Gowers has had marked success by the use of the continuous current, by placing the positive pole upon the spine or brachial plexus, and the negative pole upon the affected muscles, and persistingly persevering for months. At the same time Arsenic in moderate doses is given by the mouth, and sedatives like Conium or Morphia or Indian Hemp may be given as indicated. Bromide of Sodium, in daily doses of not less than 90 or 100 grs., should have a fair trial. It is needless to say that the lesion of which the athetosis is a sequel will require attention.

BALANITIS.

Where this condition comes on in young subjects with long prepuce, as the result of retained secretion, drawing back of the foreskin and thorough cleansing of all discharge several times daily, dusting the part with a powder consisting of equal parts Lapis Calaminaris, Boracic Acid, and Powdered Starch, soon effect a cure. When the disease is very chronic or apt to return, circumcision should be performed, especially if phimosis be present.

Should the inflammation have lasted long enough to produce excoriations of the membrane lining the prepuce or of the surface of the glans, they should be touched lightly with Nitrate of Silver, Nitric Acid, Carbolic Acid, or Liquor Hyd. Pernit., and covered with a piece of dry lint inserted between the glans and foreskin. Where the prepuce cannot be drawn backwards, a fine syringe should be used frequently to inject a stream of tepid water, coloured with Condy's Fluid, between the opposed mucous surfaces. Afterwards a weak Corrosive Sublimate Solution (1 in 1,000), or Nitrate of Silver (1 in 100), or Yellow Wash may be injected. If the foreskin can be drawn back, any of these applications may be inserted upon lint and left *in situ*.

Where the balanitis is part of a gonorrhoea, rarely will it be necessary to do anything but inject Potassium Permanganate (1 gr. to 2 oz.) round the glans and also down the urethra, curing both complaints at the same time. If there be much pain and redness, a Lead and Opium lotion applied outside on lint gives relief. Acupuncture is generally bad practice. Should there be a chancre or sore or ulcer causing hæmorrhage, one free cut, slitting up the prepuce on its dorsal aspect, should be made, and

Lime Water, Sulphate of Zinc (1 in 100), Boracic Acid (1 in 50), or Carbolic Oil (1 in 15), may be used as a dressing; or Oleate of Zinc or Boracic Ointment may be applied.

The writer has permanently cured many cases by periodically dilating the prepuce with phimosis forceps or dressing forceps

after the irritation subsided, even where the orifice hardly admitted a thick probe, and this, too, in adults. When the stretching is done with patience and care, no pain results and no inflammation follows.

BALDNESS.

For the thinning of the hair, beginning at the vertex and gradually progressing towards the forehead, or beginning in the frontal region and extending backwards, much difficulty will be found in checking its progress. Very often the cause of the condition is seborrhœa sicca (dandruff), and if the case be got early the baldness can be arrested or cured by the liberal use of animal fats with antiseptics. If the baldness be due to senile change, treatment is useless. In ordinary cases where the health is good and where there is nothing to give a clue to the cause of the baldness, the treatment will consist of local stimulation to the atrophied hair bulbs.

The best remedy is Galvanism. A slow continuous current passed through the scalp by brush electrodes has a powerful influence over the nutrition of the hair bulbs in their early stage of atrophy. Cutaneous massage, shaving, shampooing, or blistering the scalp may be tried, but the most convenient and effectual plan is by the application of irritants or stimulants in such proportion that actual vesication is avoided, and a chronic congestion or erythema is habitually kept up.

Foremost amongst remedies of this class comes Cantharides, which may be combined with other local stimulants. The writer has found the following the best combination —

R. *Olei Rosmarini* ℥iv.
 Liquor. Epispastici ℥ij.
 Olei Amygdal. Dulc. ℥ii.
 Spt. Camphoræ ℥in.
 Glycerin. Boracis ℥j
 Olio de Rosa gtt. viii.
 Tinct. Jaborandi ℥j. *mixc.*

Fiat Linimentum. Sig.—"To be well rubbed into the roots of the hair morning and night"

Gull's Linimentum Myristicæ (1 part of expressed Oil of Nutmeg in 3 of Olive Oil) is a safe and mild stimulant.

Innumerable drugs have from time to time been praised as specifics—Paraffin Oil is perhaps one of the best. The writer has seen the following pomade produce good effects, he has devised

this formula after many trials. It may be tried where lobons cannot be used.

R. *Pilocarpinæ Hydrochlor.* gr. xx.
Aquæ Destillatæ ℥ij. *misce.*

Fiat solutio et adde

Lanolin Puriss. ℥x.
Olei Petrolei ("Snowflake") ℥vi.
Olei Bergamot. ℥ss.
Olei Verbena ℥ss.

Fiat Unguentum.

Pilocarpine appears to possess some influence over the nutrition of the hair, and it has been administered hypodermically and by the mouth in various forms of alopecia, and even in universal baldness. Arsenic certainly has some effect upon the hair when administered internally. Restoration of hair having been observed after the use of Thyroid Extract, M. Moins suggests its administration in baldness.

Ammonia is a good stimulant, and may be applied with Cantharides. Erasmus Wilson recommended the following to be rubbed in once or twice a day:—*Liq. Ammon. Fort.*, *Chloroformi*, *Ol. Sesami*, and *Ol. Limonis*, of each $\frac{1}{2}$ oz., and *Spirit. Rosmarini* to 4 oz.

Capicum, Mustard, Euphorbium, and strong Acids have been used, but their application is not to be advised. The Volatile Oil of Mustard, if well diluted, is of some value—*Olei Sinapis*, 2 drs.; *Olei Petrolei*, 1 oz.; *Olei Olivæ*, 9 oz.; *misce.*

For syphilitic baldness, in addition to the usual constitutional treatment, a pomade made by adding 2 drs. of White Precipitate to 4 oz. ordinary Marrow Oil is of value.

Upon the supposed parasitic nature of common baldness all sorts of germicides have been used. They can only be of use when applied in such strengths as to cause irritation. The best is the White Precipitate pomade, and next comes solutions of Perchloride of Mercury. The treatment of ordinary seborrhæic baldness, if the researches of Sabouraud on its constantly-present bacillus be accepted, will in the future consist chiefly of antiseptics.

The growth of hair, as pointed out by Crocker, is always largely dependent on the general vigour, and no matter what local agents are employed, the general health must be closely looked after.

ALOPECIA AREATA.

Two theories regarding its pathology dominate all plans of suggested treatments.

One set of authorities, considering the disease to be a neurosis, recommend remedies for improving the general health, and tone of the nervous system in particular, as Iron Strychnine, Arsenic, Phosphorus, Sulphur, Massage, &c., with generous diet of fats, phosphates, crushed wheat and fish, and the local application of the Faradic, or Continuous Current, Hypodermics of Pilocarpine, and the host of rubefacients from Oil of Mustard, Cantharides, and Cotton Oil to Iodine. Every remedy useful in ordinary baldness has its advocates, but the majority of observers agree that Vaccination affords the best results and it does not seem to matter now how the blistering is effected. Cutaneous massage of the scalp has its strong advocates; it must be done many times a day and most thoroughly.

Another set of dermatologists believe that the disease is parasitic, and they recommend that remedies to be effective must be germicidal, consequently nearly every agent valuable in ringworm has its advocates, and the literature of the subject has become more extensive than the disease appears to justify.

Finsen's Phototherapy has given marked results (see under Lupus), and several cases have been rapidly cured by exposure to the chemic rays.

O-Dumesnil applies a 3 per cent Solution of Creolin to the entire scalp, and to the patches rubs in a 1 gr. per oz. Sublimat Ointment. Leistikow applies a 25 per cent. Chrysarobin Stick. Many authorities apply strong Carbolic Acid to the patch, and some speak strongly of the value of Iodized Collodion, Oils of Eade Wintergreen, and Cinnamon, and 1 per cent Ointment of Bismuthide of Mercury, and Trichresol. Crocker succeeds best with 1 to 5 grs. Sublimat, 1 dr. Spirit, and 7 drs. Turpentine or Ol. Pini Sylvestris.

A study of the numerous reports of these various anti-parasitic remedies shows that the best results are constantly obtained by those agents which cause the most irritation.

The strong solution of the Pernitrate of Mercury, lightly brushed over the spot, often succeeds, and the writer has seen better results from painting over the patches with strong Sulphurous Acid than from any other treatment, save constant blistering with Liquor Epispasticus. After a time if there be no signs of the growth of hair upon the bare patch the blistering should be stopped, and the milder stimulating compounds previously mentioned may be applied.

BED SORES.

Where they may be expected, as in tedious fevers, paralysis, and bladder cases, all pressure must be avoided over the prominences of the sacrum and trochanters by frequent altering of the position of the patient and by the use of water beds or air cushions, avoiding feather beds and under blankets and mackin-

be a tendency to dryness of the skin and should be rubbed in instead of the powder. If redness permanently established, painting over with Collodion may ward off the threatening ulcer, however, already occurred, a piece of lint warmed should be placed over the spot, applications stopped. An ointment composed of powdered Camphor and 1 oz. Zinc Ointment may be used at this stage, and may prevent the abrasion being made.

The treatment of this affection should be continued by proper cleanliness and skilful nursing in all cases bed sores should never be seen.

If sloughing has already taken place the applications should be continued only till the slough separates, and mistake to apply these poultices when too late, and the vitality of the surrounding skin, and best of each the sore should be syringed or doused with Alum (1 in 100), Chlorate of Potash (1 in 100), or 40). Should there be much fetor, Solution of Potash (1 in 400) may be used, or the slough may be removed with powdered Boracic Acid.

After the separation of the dead matter, the wound made clean and sweet, it is to be treated with applications of any of the previously mentioned upon lint, covered over with oiled silk held in place by soap plaster. The best lotion in the majority of cases is Lotion (1 to 2).

The continual moisture of the lotion, in some cases cause some irritation of the healthy skin and in these cases an ointment is better. The following may be made by mixing 2 oz. Basilicon Ointment with 1

zinc, which is separated from the skin over which it lies by a piece of wash-leather soaked in vinegar. Healing is very rapid under the galvanic action thus set up.

Under the heading of Ulcer will be found a list of the various applications which may be used for the healing of the sore if the above fail. Whilst the healing process is going on it will be advisable, and in some cases absolutely necessary, to remove all pressure from the sore; the various air and water cushions will generally prove useless. The best plan will be for the physician to direct the nurse to make a small cushion out of soft old linen or calico, and stuff it with sheep's wool carefully teased out. This appliance can be shaped to the irregularities of the part, with a circular opening in the centre opposite to the bed sore.

BERI-BERI.

The evidence is accumulating that this strange affection is caused by a microbe whose poison produces peripheral neuritis. Those who regard it as a "Place" disease attach the first importance to removal to a higher, drier, and better ventilated region, with absolute cleanliness and improved environment, and absence of all crowding. Those who look upon it as a "Food" disease regard dietary as of primary importance, and urge the necessity of a varied and generous regimen of beans, barley, and wheat, instead of the rice so often blamed in many epidemics. It is certain that a removal from the region in which the disease has appeared and a change of diet is of more importance than a drug treatment. Symptoms must however be met by appropriate remedies as they appear. Diuretics and Purgatives are indicated, and Salicylates with Quinine may be freely given, and at a later stage Iron, Strychnine, and Electricity when the pain and hyperæsthesia have passed away.

Nitrate of Silver is of undoubted value alone, or combined with Belladonna in the dry form of the disease and where serious signs of heart failure appear from over distension of the right ventricle Manson does not hesitate after the failure of Amyl and Glonoin and drastic purgatives, to bleed from the arm. Digitalis may from the first be combined with diuretics like Acetate of Potash and Jumper.

BILHARZIA HÆMATOBIA.

This hæmatozoon which inhabits the veins, chiefly the smaller branches of the portal vein, promises to afford considerable interest to British practitioners since it is so very prevalent in the Transvaal, and so liable to infect the members of the large army stationed there. It is conjectured that the parasite gains admission to the body during the act of bathing. Hence the preventive measures must be such as will avoid the necessity of fresh water bathing, and which will secure the sterilization of all drinking water. There is no remedy which will destroy the parasite once it has

gained admission, though in Cairo where the disease is also common it is treated by full doses of Male Fern. The physician has to content himself with treating the symptoms as they arise. The chief of these is the hæmaturia and bladder irritation which often eventuates in the formation of a calculus round some blood clot or cluster of ova.

Large draughts of barley water acidulated with lemon juice to which moderate doses of Boric Acid may be added, cannot fail to give relief, and a saturation of the blood of the patient with Creosote might in the long run prevent the development of the parasite. The writer would suggest that in a severe case the patient should be kept under Chloroform or Ether for as long a period as possible, compatible with safety, in order to ensure thorough saturation of the blood with the Chloroform vapour.

BLACK WATER FEVER.—See Hæmaturia (Malarial).

BLADDER, Atony or Atrophy of.

The treatment of this affection in its early stages will generally mean the removal of the obstruction to the flow which has caused the distension and wasting of the muscular coats. In the later stages the treatment will be that indicated for chronic cystitis. The habit of retaining the urine for too long a period must be abolished, stricture of the urethra must be dilated, and accumulations of faeces in the rectum should be cleared out. Tumours, calculi, or enlarged prostate will require attention, and those spinal lesions (sometimes caused by injury) or cerebral affections which lead to retentions will require appropriate treatment.

Drugs are of little value in improving the tone of the bladder muscle but some improvement may be obtained by general hygienic measures and full doses of Strychnine and Iron, or Easton's Syrup, Ergot, or minute doses of Cantharides. The Constant Current is of undoubted value; but judicious Catheterisation, with clean rubber instruments and the administration of remedies to keep the urine normal, as enumerated under the treatment of Chronic Cystitis, will make catheter life tolerably comfortable.

Dr. Wales had obtained excellent results from 2 oz. doses of a 1 in 20 infusion of Golden Rod (*Solidago Virgaurea*) every four hours.

Perhaps one of the best combinations is the following:—Ergotin, 1 gr.; Extract of Nux Vomica, $\frac{1}{2}$ gr.; Reduced Iron, 2 grs., three times a day.

BLADDER, Acute Inflammation of.

The treatment of this affection will depend upon the cause. Thus if the cystitis be the result of an extension backwards of a gonorrhœa—a common cause—absolute rest in bed and warmth, hot baths or hot hip baths (t. 105°, frequently repeated, and a

suppository of $\frac{1}{2}$ gr. Morphia or $\frac{1}{2}$ gr. Green Extract of Belladonna should be given to allay pain and spasm. In a few cases the pains will be agonising, and will not yield to Opium in safe doses. 10-20 minims of a 4 per cent solution of Eucaine injected into the bladder will then be found of the greatest service, and will give prompt relief, lasting for some hours.

Hangs speaks highly of the effect of 10 drops of 5 per cent. solution of Nitrate of Silver instilled into the bladder for the relief of severe pain in acute cystitis.

Stimulants and solid food must be stopped, and coffee and tea forbidden. The diet, whilst the acute stage lasts, should be entirely milk, or milk diluted with barley water, and kali water, acid, if the patient can take it. A large Linseed poultice covering the lower part of the abdomen gives relief.

Hyoscyamus, in doses of 20 to 40 minims of the tincture, should be given every 4 or 6 hours, according to urgency.

Opium may be combined with it in doses of 15 minims of the tincture. This may be given in Infusion of Linseed, freshly prepared, to each small cup of which 20 to 30 minims of Liquor Potassæ are added. There need generally be no fear of increasing the pain by taking moderate amount of diluent drinks. Injections for the gonorrhœa should be stopped, and not resumed till urgent symptoms subside, then weak, warm injections of water, coloured with Condy's Fluid, may be commenced, gradually and cautiously increasing the strength till 1 gr. Permanganate to each oz. can be painlessly used.

Where the acute cystitis is the result of an attack of gout, smart Saline Purges, followed by Colchicum and large doses of Bicarbonate of Potash, are indicated.

The attack sometimes follows the application of a blister to some part of the body, and, when the first signs of cystitis supervene, the blister should be instantly removed and a large warm poultice applied over its site, 40 minims of Laudanum per rectum given, Hyoscyamus internally, and hot hip baths and diluent drinks soon relieve all trouble in a few hours. (See under Strangury.)

When the attack follows irritation from injury or stone, the removal of the exciting cause, after relieving pain by the above treatment, should be attempted. (See Stone in the Bladder.)

Where the urine shows signs of decomposition it is most undesirable in the acute affection to pass instruments and wash out. 15 grs Boracic Acid dissolved in some diluent, like barley water, or 5 grs. of Salol three times daily, will meet the requirements of the case. If washing out should become imperative only one or two ounces of the solution should be injected.

BLADDER, Chronic Inflammation of.

The cause, if possible, should be determined and treated. The causes are—(1) Atony of the bladder, (2) Calculus, (3) Tumor, (4)

Stricture, (5) Enlarged Prostate, (6) Paralysis affecting the spinal centre, (7) Uterine affections, (8) Gout, &c.

In those cases where the immediate removal of the cause is not possible, the first indication is the systematic use of the catheter. This is imperative, as pain and frequency of micturition will not disappear until the complete evacuation of the contents of the bladder. The intervals between the use of the catheter are to be gradually lengthened, until morning and evening catheterisation be sufficient. As a rule, very considerable relief will attend the removal of all the urine contained in the bladder, and the catheter need not be again used till *slight* symptoms of distress are felt. On the first passing of a catheter in the cystitis caused by residual urine it is wise not to draw off all the residual urine, or, if necessary for diagnostic purposes, a few ounces of Boracic solution may be injected before withdrawing the catheter. After the attack of cystitis seems to be passing off, as the urine gets clear the catheterisation may be suspended. If enlargement of the prostate or central nerve lesion be the cause, the habitual use of the catheter will probably last during the patient's lifetime. Soft India-rubber instruments should be used, and, as a rule, oil should not be employed for their constant lubrication, as its action upon the rubber is such as to make the instrument brittle and liable to break off in the bladder or passage. There is nothing so good as a lubricant as the Glycerin. Boracis B.P.; it is a good antiseptic, and sterilises the instrument each time—a matter of vital importance.

Occasionally, but not often, it may be necessary to tie in a catheter, and then only a rubber one should be used.

Injectons into the bladder after washing out the organ are in favour with most surgeons, and many substances are used for this purpose, and several instruments are recommended. The best, and one that answers every requirement, is a couple of feet of India-rubber tubing, such as is used for children's feeding bottles, attached at one end to a small glass funnel, at the other by means of a bit of fine glass tubing it is connected with a large-sized rubber catheter. Upon the patient lying down and inserting the catheter into the bladder he draws off the urine, and by elevating the funnel and pouring in a few ounces of tepid water it finds its way into the bladder, after which depression of the funnel permits it to flow out again, and thus every particle of mucus can be washed off the coats of the viscus, or the bladder may be irrigated without the introduction of a catheter, the funnel being raised 6-10 feet above the bladder, when the pressure will overcome the resistance of the urethral muscles, and the fluid will trickle into the viscus. Any of the following solutions can then be poured in, and the bladder thoroughly washed out with them, only permitting 4 to 6 oz. to remain in at once. They should not be used if there be much pain or tenderness:—

Nitric Acid, as much as will make water pleasantly acidulous to

the mouth ; Boric Acid, 1 to 2 drs. to water 10 oz. It may be used in saturated solution. The following quantities of the various drugs will make with 10 oz. of warm water a solution for injecting—Carbolic Acid, 1 dr. ; Quinine, 15 grs. ; Nitrate of Silver, 3 grs. ; Sulphate of Copper, 5 grs. ; Sulphate of Zinc, 5 grs. ; Permanganate of Potassium, 3 grs. ; Resorcin, 1 dr. ; Chloral Hydrate, 10 grs. ; Corrosive Sublimate, 1 gr. ; and Creolin, 1 dr. ; pure, fresh, healthy Urine ; pure Castor Oil gently warmed.

Of these Boracic Acid is unquestionably the least irritating, and though its internal administration renders washing out of the bladder seldom necessary, still it may be occasionally used with freedom, and a quart of the solution may be used at one sitting in small quantities at a time.

Recently injections of Antipyrine have been extolled for the relief of pain in cystitis and for their antiseptic effect. Vigneron injects 4 ozs. of a 1 per cent solution after washing out, and allows it to remain. He injects before washing out about $\frac{1}{2}$ oz. of a 4 per cent solution, which is to be retained for 10 minutes.

Graham speaks very highly of the value of Pyoktanin. 3j of a saturated solution are injected, after the bladder has been thoroughly washed out, and allowed to remain for a minute or two, the organ is then again washed out with boiled water till the water returns free of any blue colour. The treatment is repeated every 10 days.

Nitrate of Silver, 1 gr. to 10 grs. to the ounce, may be used in the same way.

A large number of drugs possess considerable power over the bladder and urinary secretion as they pass out after being administered by the mouth, and much benefit may be obtained by their administration in chronic cystitis.

By far the most valuable of these is Boracic Acid, and there are few more surprising results in therapeutics than is to be seen after a few doses of this drug. Urine, which is passed ammoniacal and so highly offensive as to pollute the air of the sick-room, may, in 48 hours or less, be voided clear and free from every trace of smell after 15 grs. of the acid 3 or 4 times a day in a glass of water or milk.

The administration of this drug will, in most instances, enable the surgeon to dispense with washing out and injecting solutions into the bladder. After some days the dose may be diminished to 5 grs. thrice daily. The only objection to its administration rests in its liability to irritate the stomach and destroy the appetite. This is less likely to occur if it be largely diluted, and the writer dilutes 10 grs. with half a pint of kali water or with one pint of milk, under these precautions it may be taken for many weeks without inconvenience.

Newman has observed that where there is disease of the kidney the internal use of the acid generally disagrees, and the writer had repeatedly satisfied himself of this.

Creosote is a drug of undoubted value, and the writer has kept the urine sweet for weeks by administering four 2-minim capsules in the day. Salol is also efficacious, but not so safe when the kidneys are diseased.

Urotropin, in doses of 3 to 10 grs. three times daily, especially valuable in severe ammoniacal cystitis and long-standing pyuria.

Buchu, in doses of a large wine-glassful (3 to 5 oz.) of the infusion three or four times a day, is indicated in recent or acute cases; if improvement does not soon follow, its use may be suspended, and

Triticum Repens, made into a decoction by boiling 4 oz. of the fresh rhizome in one quart of water and taking the entire quantity during the 24 hours, may be followed by marked improvement.

Sir H. Thompson advises, in chronic cases with much mucous and alkaline urine, either the infusion of

Alchemilla Arvensis, 2 drs. in 5 oz. water, 3 times a day; or

Uva Ursi, in doses of a wine-glassful of the infusion; or

Pareira Brava, in doses of a wine-glassful of the decoction 3 or 4 times a day.

Any of these vegetable remedies can be most effectually combined with 5 gr. doses of Boracic Acid.

Zea Mays (drachm doses of the liquid extract) is a drug of much value.

Alkalies, as Bicarbonate of Potash or the *Liquor Potassæ*, are of great value in cystitis, and may be given in combination with any of the above, or with *Hyoscyamus*.

Benzoic Acid, in doses of 10 to 20 grs., in passing out as Hippuric Acid, acts as an antiseptic, and also diminishes the alkalinity of the urine. Its various salts may be administered in the same way.

Mineral Acids have scarcely any appreciable power in diminishing the alkalinity of the urine in cystitis, and their administration with this intention ends in disappointment.

Hyoscyamus is a remedy of great value for the relief of pain in cystitis. Corrie strongly praises Chloride of Ammonium in various forms of cystitis. He gives a capsule 3 or 4 times a day, fasting, to be followed by a tumblerful of cold water. The urine clears up rapidly and discomfort soon subsides. 10 to 15 grs. may be conveniently given in solution or wafer paper.

Freudentberg has published reports of some 56 cases of cystitis treated by small doses of Cantharidin. 32 of them were rapidly and completely cured, and the others relieved. He states that the remedy is only approached by Sandal Wood Oil, and in none of his cases were any unpleasant symptoms noticed.

Belladonna, chiefly in the form of a suppository, has been before referred to, as has also been Morphia. Belladonna, in small doses by the mouth, is often successful in mild cystitis in children.

The writer finds a combination of Oil of Sandal and liquid extract

of Saw Palmetto is one of the most valuable of all vesical sedatives. This is stated to be the composition of Sanmetto, which is so valuable in prostatic cases. Phenacetin and Antipyrine in 10 gr. doses sometimes act satisfactorily.

The diet and general care of the patient should be upon the same lines as indicated for acute cystitis:—Change to a warmer and drier climate, with the use of natural alkaline water like Vichy or Vals, or the sulphur waters of Bonnes or Harrogate, may do much to restore the patient. Avoidance of stimulants, exposure to cold and wet, and fatigue of body, especially long carriage or omnibus drives must be carefully guarded against. The sterilised catheter is to be used to ensure complete evacuation.

Turpentine, Eucalyptus, Copaiba, and Cubebs are often administered, but their effects are uncertain and so often followed by renal irritation that they should be administered with great caution.

Finally, intractable cases should be carefully examined by the cystoscope, when the cause will frequently be discovered. When all else fails the bladder must be drained either by (1) a Catheter tied in, (2) Perineal Cystotomy; (3) Supra-pubic Cystotomy.

BLADDER, Irritability of.

The treatment will entirely depend upon the cause, which must first be removed, after which the symptom will speedily subside—thus phimosis, stone, stricture, sexual excess, prostatic troubles, gout, rectal fissures, hemorrhoids, irritating conditions of the urine, &c. Where, after sounding, and the use of the cystoscope, &c., no cause is found, the bladder sedatives mentioned on the previous pages are to be tried. If the condition becomes formidable and distressing, a small incision may be made as in Allarton's median lithotomy operation, and temporary drainage of the bladder secured, which generally gives immediate relief and sometimes effects a permanent cure.

BLEPHARITIS OR TINEA TARSI.

The first object is to remove the minute scabs or crusts before applying any remedy. This can only be done by carefully bathing the eyelids with a warm alkaline lotion (2 drs. of Bicarbonate of Soda or Borax to 1 pint water) for half an hour till the crusts come easily away, after which the margin of the lid is carefully dried, and an ointment of the Yellow Oxide of Mercury (8 grs. to 1 oz. Vaseline) freely smeared over it. This treatment must be carried out twice a day at least, and must be persevered with for weeks till every trace of the disease disappears. Should it fail, which is seldom, unless through carelessness, the edge of the lid should be painted with strong solution of Nitrate of Silver (1 drachm to 1 oz.), and the ointment continued. Should there be much inflammatory symptoms, Epilation is of great value, and recent cases may be speedily cured by removing the hairs and applying the above mercurial or the Diluted Citrine Ointment. The disease.

often occurs in the anæmic and strumous, and sometimes local remedies are of no avail, unless after a prolonged course of Iron, combined with Cod Liver Oil, extra feeding, pure air, and a change to the sea-side.

BOILS.

The patient should have careful attention to general health—a generous, plain, unstimulating diet, without alcohol or wine in the early stages. There is nothing influences the growth of boils in the writer's opinion, like a diet into which onions largely enter. The Spanish onion boiled till tender in an open vessel may be eaten *ad lib.* at supper or breakfast, or at both times. The gentle purgation following is also an advantage. Some benefit has been reported to follow doses of $\frac{1}{4}$ gr. Sulphide of Calcium as a prophylactic in the early stages, or to assist maturation at a later period. There is, however, little evidence to show that it behaves in this paradoxical way. Sulphur Waters (Bonnes, Harrogate, &c.) may be given with benefit. Fresh Beer Yeast in doses of a tea-spoonful of the fluid form, three or four times a day before meals, is most effectual in preventing boils when threatening, and flour (wheaten) in table-spoonful doses, mixed up in cold water, is stated to act similarly.

Quinine, in doses falling short of cinchonism, is also used, and Iron, to the point of saturation of the system, has its advocates. Sir J. Paget recommends Liquor Potassæ internally in gony cases.

Upon first appearance of a boil, it is worth while to scrape the skin over it with a sharp scalpel till a drop of blood appears, or pluck out the hair growing in the inflamed follicle, as it is said these means may often prevent suppuration. The spot should then be brushed over with (1) the strong Solution of the Acid Nitrate of Mercury, or (2) Collodion, or (3) strong Solution of Nitrate of Silver (1 dr to 1 oz.), or (4) Ichthyol Varnish (Ichthyol 1, water 3)—Wurz strongly recommends Thiol, as free from smell and more efficient than Ichthyol—or (5) a compress soaked in a solution of Chloral (25 per cent.) in glycerin and water, may be laid upon it. Salzwedel's alcoholic dressings consist of pads of lint or wool, soaked in alcohol and covered with oiled silk perforated with small holes. Sometimes one or other of these remedies causes abortion of the boil, but their effects are very uncertain. It is better to either cover the boil at this stage with a little Extract of Belladonna rubbed down with glycerin, or to apply a small piece of Belladonna and Opium plaster, in the centre of which a hole may be cut when the boil points. 50 per cent. Salicylic Acid Plaster has been highly recommended. Should there be much pain or throbbing, a good Linseed poultice, smeared over with Boracic Acid Ointment should be applied, or a sponge squeezed out of very warm water may be frequently used. Wet applications covered with oiled silk should be avoided owing

to the danger of crops of small boils appearing where the silk is in contact with the healthy skin.

Sometimes strapping the boil with strips of plaster affords relief, at other times it occasions great pain. An incision should be made if the tension cause constitutional disturbance; one moderately free wound will do good; the crucial incision is needless. Pain may be somewhat relieved by the application of Cocaine, and the pain of the incision may hardly be felt if strong Carbohic Acid be previously painted over the boil.

The application of a poultice to clean the sore at this stage assists matters and the boil may now be dressed with any antiseptic ointment or lotion, the former being preferable.

The early incision and the sparing use of poultices have an influence in preventing successive crops appearing.

The injection of Carbohic Acid into boils in their early stage is painful and not free from danger. A 5 or 3 per cent. solution injected into the centre of the boil can do little harm and may stop the suppuration. A few minims of Tincture of Iodine may be also tried in the same manner.

During the suppurative stage, if many boils be present, the diet may be enriched, stimulants and strong soups may be given, and change of air may be advisable.

Iron and Arsenic now are useful, or Iron and Chlorate of Potash may be freely administered. Sulphites and Phosphate of Soda have their advocates. Saline Purgatives and Sulphur Waters may be given at a later stage.

Grosch has found that a Solution of Acetate of Alumina (1 in 4 of water) causes the speedy abortion of furuncles in the external auditory canal. The writer uses the B.P. Solution of Corrosive sublimate dropped into the ear twice a day; after its instillation cotton wool soaked in it should be left in the canal. This treatment will effectually prevent the return of the affection. Boracic acid may be insufflated, or a strong Alcoholic Solution instilled.

BONE, Diseases of—See Caries, Periostitis, &c.

BREAST, Abscess of, and Inflammation of—See Mammary Gland.

BREAST, Cancer of—See Cancer.

BRIGHT'S DISEASE, Acute.

The patient should be at once placed in bed between blankets, and enveloped in a sleeping suit of light flannel. The diet should consist entirely of milk in small quantities frequently administered, malt-milk, or milk and barley water, or milk and kaff water, and diluent drinks as potus imperialis. Stimulants in every form, animal food and eggs must be at first rigidly prohibited. After the acute symptoms pass off, any farinaceous food may be allowed. The chief indications for treatment are to act upon the skin,

bowels, and kidneys, so as to cause elimination of products hurtful to the economy. Sometimes the indications may be limited to the removal of these products by the skin and bowels alone if the kidneys be in a condition in which their functions are for the time in suspension.

DIAPHORETICS.—Drachm doses of the Liq. Ammon. Acetatis, with 20 minims of Spt. Æther. Nit., afford a harmless and often efficient method in which to start the action of the skin in mild cases. Should there be feverishness present, 2 minims of the Tr. Aconiti may be added, and the dose administered every 2 or 3 hours.

R. *Tinct. Aconiti* min. xxxij.
 Polassa Citratis ℥iv.
 Liquoris Ammon. Acet. ℥ij.
 Aqua Camphoræ ad ℥viij. misce.

Fiat mistura cujus capiat cochleare magnum omni hora.

Generally it will be safe to assist such a diaphoretic by copious draughts of warm whey.

In severe cases diaphoretic drugs are not to be depended upon.

Baths are much more certain in their action. The ordinary hot bath (104°) may be used, but is objectionable owing to the exposure entailed and the difficulties in getting the patient into and out of the bath, which very often cannot be brought into the sick-room. Liebermeister places the patient in a hot bath at a temperature of 100°, and adds hotter water till the temperature reaches 106°, in which he keeps the patient from 20 to 60 minutes, after which he is taken out, rubbed down, and packed in sheets or blankets for 2 or 3 hours till a profuse perspiration takes place.

The writer, always in severe cases where there is any threatening of uræmia, has a large vessel brought into the sick-room into which water, almost boiling, is poured till it is half filled (into this a few ounces of Mustard may be stirred), a large, thick, double blanket is thrown in, and in a few minutes wrung out by the attendants, so that the superfluous moisture is got rid of. In this the patient is carefully enveloped—all the body being included save the head and face. There is no danger of scalding owing to the rapid reduction of heat caused by the evaporation from the large surface of the flannel and indeed there is generally some difficulty in having the blanket warm enough. It should be as hot as the hands of the attendants can bear when wringing it out.

After envelopment, the patient should be placed upon a mattress or pailasse of straw and covered with sheets and blankets for a couple of hours till a profuse perspiration occur. He is then

rubbed dry and placed between warm blankets. When in this pack he may drink freely of any warm diluent like barley water or whey.

The hot air bath is more convenient, though not so certain; it is generally all that is necessary in mild cases. Of it there are two forms—one consisting of a large copper spirit lamp enclosed in gauze, like a Davy lamp, and surrounded by a cradle of sticks to keep off the bedclothes. It is lighted and placed between the patient's knees, and the bedclothes tucked in lightly all round him the head and face only being left free. Half an hour generally produces a very free perspiration. The writer has seen the death caused by burns through the negligence of a nurse, but with ordinary care an accident is hardly possible with a quiet, conscious patient. A second form of bath can be obtained from most surgical instrument makers, in which the spirit lamp is placed on the floor of the room, and the heated air caused by the combustion is conveyed under the bedclothes by a wide tin telescope tube. Perfect safety is thus obtained if the nurse does not upset the lamp and spill the ignited spirit over carpets and bed hangings.

Sir J. Simpson's poor man's bath is made by filling a number of soda water bottles with very hot water, and drawing over each a woolen stocking squeezed out of hot water, and placing them alongside the patient under the bedclothes.

In ordinary cases the Turkish bath is not available, but it may be used in chronic Bright's disease with advantage.

The hot pack or hot air may be given daily or even oftener where uræmia is threatening, or where anasarca is very extensive. They must, however, be used with some discretion, especially if there are marked signs of cardiac failure or great dyspnoea.

Should all these methods fail in inducing free and abundant perspiration, the physician has still a most powerful diaphoretic in Pilocarpine, and the writer finds that if administered *whilst the patient is in the pack*, it acts more rapidly and safely. From $\frac{1}{2}$ to $\frac{1}{4}$ gr. (generally $\frac{1}{2}$ gr. will be sufficient), when injected subcutaneously in a few minutes produces copious sweating and a very great discharge of saliva. It may be given by the mouth just before the patient is placed in the pack, and a dose of Sal Volatile, or a hypodermic of Strychnine, will overcome any depressing effect upon the heart.

DIURETICS.—It is advisable to administer mild diuretics so as to wash out the kidney tubes and flush away casts and epithelial debris. The best remedy is water in copious draughts, or any diluent drink like whey, barley water, or linseed tea, hot or cold, as the patient wishes.

Spt. Ether, Nitrosi and the Citrate and Acetate of Potash are harmless diuretics, whilst Squill, Broom Gin, Juniper, and others possessing a stimulating power are not safe.

Digitals is the safest and best diuretic, in the absence of high tension, and is generally admissible, and so is Caffeine after the subsidence of the very acute stage. Where the tension is high, and urinary secretion scanty these drugs must not be employed, the best remedy will be found in Nitroglycerin in doses of $\frac{1}{4}$ minim of a 1 per cent. solution every hour. It often materially increases the secretion of urine with promptness. Methyl-Blue in capsules ($\frac{1}{4}$ gr.) has been tried. It must be remembered that the action of diuretics in Bright's disease is most uncertain and unreliable, and the physician must trust to the skin and bowels for the elimination of products whose presence in the blood may lead to a fatal issue.

PURGATIVES. Only those are indicated which cause copious watery motions. Elaterin and Elaterium are generally given in desperate cases, and it is in such cases that absorption from the stomach may be in such a condition as to render their action void. They are, therefore, not to be relied upon. A dose may have no effect, which in health would cause serious purging, and if a second dose be administered, dangerous prostration might supervene should the absorption of both doses take place eventually.

Pulv. Jalapæ Co. in drachm doses is the favourite remedy, but the best results will be always obtained from Sulphate of Magnesia.

R. Mag. Sulphatis *ʒii.*
 Mag. Carb. Pond. *ʒii.*
 Aque M. Pip. *ʒxii. misce.*

Fiat mistura. Signa.—"A wine-glassful every 2 or 3 hours till purging supervene, then half a wine-glassful every 4 hours to keep up the discharge of watery motions"

Another method of giving this drug in cases of great anasarca will be presently mentioned.

Calomel must not be administered owing to its dangerous depressant action in kidney diseases notwithstanding its recommendation by high authorities, and the young practitioner will act wisely in also avoiding Opium and Cantharides.

Other symptoms must be met by appropriate treatment. Thus pain in the renal region requires the application of hot poultices, and if the inflammatory action runs high, local blood-letting by leeches or wet cupping over the loins must be resorted to; and should there be fever with a full bounding pulse, suppression of urine, and signs of approaching coma or convulsions a vein in the arm should be opened and 10 or more ounces of blood allowed to flow freely from a large orifice. Bozzolo, after bleeding, dilutes the remaining blood by the subcutaneous injections of sterilised saline solution or serum.

After the acute symptoms have subsided, counter-irritation over the loins may be called for. Mustard answers every purpose, but blisters should never be employed, and for the same reasons which make Cantharides a dangerous drug when given in renal affections. Cupping is unobjectionable. Should anasarca remain, the action of *Digitalis* may be kept up.

The following is a splendid combination at this stage —

R. *Tinct. Ferri Perchlor.* ℥vi.
Aquæ Ammon. Acl. ℥iii.
Aquæ Chlorof. ℥vi. *misce.*

Fiat mistura. Capiat coch. mag. ex aquæ ℥ii quartis horis.

Potassium Salts increase the danger of uræmia, and milk owes its value in Bright's disease to its poverty in Potassium Salts.

Oxygen may be given freely in threatened uræmia.

Sulphates and Nitroglycerin may be resorted to in the later stages should arterial tension increase, and Iodides are useful also.

The treatment of various complications will be mentioned under Chronic Bright's disease.

BRIGHT'S DISEASE, Chronic.

The general treatment of the chronic affection arising out of the acute disease, or of the affection which has apparently begun in the chronic form, will differ but slightly in degree from the treatment mentioned under acute Bright's disease. The diet should be chiefly milk; eggs and strong animal foods, or concentrated soups, or stimulants, must be allowed only in very small quantities. Fats and carbohydrates are admissible in full quantities, hence the milk should not be skimmed. A dry diet is a mistake, fluids should be freely given to ensure flushing of the tubules even in the face of considerable anasarca.

The patient's body, when not in bed, must be enveloped entirely in flannels, and damp, cold, and rain avoided. A dry, equable, warm climate, in which an outdoor life may be safely pursued, is a great desideratum.

The artificial Koumiss, mentioned upon page 26, is a valuable adjunct to the diet in all stages of the disease.

The same indications are to be met in the chronic form of the disease as were discussed under the acute affection. Diaphoretics, Diuretics, and Purgatives are to be judiciously administered.

The physician will find at the bedside that he is very often called upon to treat sub-acute or acute attacks occurring upon the top of a well-marked chronic affection, and the indications are precisely alike and must be dealt with as promptly as if the attack were one of acute Bright's disease happening to a healthy individual.

If the patient be well enough to go about, the action of diaphoretics must, to a great extent, be suspended, and the

physician must be content to keep the skin in a healthy state of activity by very warm clothing, and a hot bath or hot pack at night. Diuretics are of more value and more to be relied upon than in the acute form. Digitalis is always safe, and may be given in full doses; the Tincture is the best preparation.

Notwithstanding the incompatibility between Digitalis and Iron, the combination of their tinctures makes a valuable though inorganic mixture especially indicated in the treatment of this disease. The addition of a little Phosphoric Acid keeps the mixture clear.

Diuretin sometimes gives good results when there is much dropsy.

Caffeine is a good diuretic in these cases, and some authorities believe that it diminishes the albumin and increases the elimination of solids. The writer, in a series of carefully conducted experiments, failed to find that it had any influence in increasing the amount of urea daily excreted in chronic Bright's disease. It may be combined with Digitalis or Sparteine.

Cannabis Indica has been found of service, especially as opium is contra-indicated. Sometimes it exerts decided diuretic action, and leads to rapid improvement where there is much blood in the urine, though the rationale of its action is obscure.

Copaiba, Turpentine, and Cantharides are powerful diuretics, but should be seldom employed, even in the most chronic cases, as irritation of a serious nature may follow their administration. It is fashionable to order them in infinitesimal doses which can do no harm.

Jaborandi and Juniper are valuable remedies; the former is indicated where there is much blood in the urine, and the latter where blood is absent and the total amount excreted is small. Molliere extols the application of an ointment of Pilocarpine (1 in 1,000 or 2,000 of White Vaseline); about 3 oz. of this (i.e., about 1 gr. Nitrate of Pilocarpine) is rubbed into the trunk surface and covered with cotton wool and waxed linen, and the whole maintained by bandage. Thus carapace is kept on for some hours or till the next daily injection. In acute cases rapid cure follows, and in chronic cases he maintains, it produces greater alleviation of symptoms and prolongation of life than any other remedy.

Nitroglycerin will sometimes start the kidneys to act after all other remedies fail. Half a minim of the one per cent solution may be given every hour for six or eight doses, then every second or third hour. It is indicated where the vascular tension is high.

Benzoate of Soda has been found serviceable (15 grs. 4 times daily) in threatening uræmia.

The best purgatives are Salines, and Mag Sulph., as mentioned under the acute affection, is also the most reliable cathartic in the chronic disease. Cream of Tartar is both diuretic and purgative. Purgation can be safely kept up by small doses frequently repeated over long periods. Massage is of the greatest use in chronic dropsy, as pointed out by Stewart.

With a view of diminishing the amount of the albumin, a host of specifics are vaunted, their action is uncertain, and at the best very slight. Lead Acetate in small doses, Lime Water, Belladonna, Fuchsin (1 gr. pills for children), Gallic and Tannic Acids, Astringent Iron preparations, Oxygen inhalations, Common Salt in 20 gr. doses, Chloral Benzoin of Soda, Ergot, Arsenic in small doses of liquor over long periods, Hydrastis, and Chamaejasme are but a few of the innumerable remedies supposed to diminish the amount of albumin in chronic Bright's disease. When such a result follows, as it doubtless often does, it is possibly owing to the general tonic action of the drug in improving the languid circulation through the renal capillaries. Iron, combined with Digitalis and Nux Vomica, upon the whole will give the best results. Iodides are also valuable in many chronic cases. Lactate of Strontium has disappointed most who have tried it. Mitchell Bruce insists upon the inability of drugs to check the albuminuria, and he points out that the loss of albumin is of far less importance than is generally imagined.

An absolute milk diet Yeo affirms to be the best agent in reducing the amount of albumin. He very wisely places more reliance in general hygienic measures than in drugs, and he recommends a humid, warm, equable temperature like Madeira, Cayenne, the Azores, or West Indies.

Where the anasarca continues to increase, and threaten life, notwithstanding the free use of diuretics, hot air baths, and purgatives, relief may be obtained by acupuncture of the most dependent parts. The skin should be smeared over with Lanoline or Eucletic Ointment, and a number of smart punctures made with a sharp glover's needle, whose point may be freely moved about before withdrawal. Over the malleoli, dorsum of foot, and calf are the best situations, and the limb should be enveloped in warm, moist flannel cloths, and any tendency to an erythematous condition of the skin met by appropriate remedies. Strict antiseptic precautions are essential. A Southey's minute canula may be left *in situ*. Should the dropsy continue to increase, the physician has still another remedy to try. Hay recommends that 3i Mag. Sulph., dissolved in 2 oz. water, be given when the alimentary canal is empty, after fasting and total abstinence from fluids for 12 or 18 hours. Sometimes enormous quantities of fluid are excreted from the bowels by this method, and the writer has seen a water-logged patient rescued upon more than one occasion by this means. It, however, unfortunately fails in many cases, owing apparently to the condition of the alimentary canal. Ewart advises that the dropsy should be coaxed into the lower extremities by slanting the bed, and then puncture should be made, as in this way the deadlock in the lymphatic circulation is removed, most physicians will, however, continue to regard puncture as a *desperate resort*.

Calomel is recommended for the dropsy and uræmia, but it is a

dangerous remedy, whose action is exceedingly difficult to control. Small doses have proved fatal, and as a rule Guy's Pill is to be avoided.

Where uræmic convulsions come on notwithstanding the above treatment large doses of Bromide of Sodium and 30 gr. doses of Chloral may be given by the bowels, a hypodermic dose of $\frac{1}{2}$ gr. Pilocarpine whilst in the hot pack, and the inhalation of Chloroform or Ether, afford the best results. Venesection may be tried with advantage.

These various measures, combined with the prompt emptying of the uterus, give the best hope of life in convulsions coming on at the puerperal period; in such cases blood-letting and chloroform are valuable remedies.

The various symptoms and complications occurring during the disease will be combated upon general principles. Thus ascites, hydrothorax, and hydropericardium should be treated as part of the general dropsy, and if serious embarrassments result from them the fluid must be drawn off with the trochar and canula, or by aspiration.

Œdema of the lungs must be treated by the methods employed for the general anasarca, and by sinapisms to the chest, and by the concentrated solution of Epsom Salt. On no account should Pilocarpine be administered in the face of this serious condition, as further œdema and death will probably result.

Vomiting, which is often very troublesome, may be treated by Bismuth and Iced Champagne, but the writer has seen magical results from the administration of sour Buttermilk in small quantities. (See page 28.) He was led to use it after observing its value in a case where a patient was sinking from intractable vomiting. A constant craving for this acid beverage induced a kind-hearted nurse to give it contrary to orders, and the vomiting immediately stopped. It appeared to act by neutralising the free ammonia which seemed to be eliminated by the gastric membrane.

Diarrhœa is best let alone unless very exhausting. It may be overcome by small doses of Codeine and the judicious use of vegetable astringents and mineral acids.

Anæmia, so constantly present, is best met by Iron.

Hæmorrhage from the kidneys and other regions will require astringents and the internal use of Chloride of Calcium. The effects of Jaborandi and Indian Hemp when given by the mouth have been already referred to.

Uræmic dyspnoea is best relieved by drachm doses of Sulphuric Ether, or by Nitrite of Amyl or Nitroglycerin and brisk purgation.

Sleeplessness is best relieved by Sulphonal in 20 to 30 grain doses. Opium and Morphia sometimes induce serious cerebral disturbance, and Chloral is not to be employed as a routine drug in an affection often associated with cardiac disease and degeneration. Paraldehyde acts safely and effectually, and Trional, Indian Hemp, or Hyoscine may be used.

Headache is relieved by Caffeine, Antipyrine, and Antifebrin.

Hitherto the treatment of the chronic form of Bright's disease, associated with the *large white* kidney, has been discussed. The variety of the affection characterised by the presence of the *fatty* kidney will be treated best upon exactly the same lines, the various symptoms of the diseases in which it is met (chiefly phthisis) being dealt with according to requirements.

The treatment of the *amyloid* or *waxy* form of the disease will resolve itself into the treatment of the *cause* of the affection, and in the early stages of the disease the removal of this may be followed by complete restoration. Thus the source of the prolonged suppuration must, if possible, be removed, and diseased bone extracted. Chronic abscesses may be surgically dealt with, and pulmonary or pleural suppuration, when not depending upon tubercle may be remedied by appropriate medicines, incisions, and drainage, with a change to a warmer climate. Syphilis in its protein tertiary phases may be combated, and the patient placed in a fair way towards recovery if the disease has not lasted too long. Large doses of Iodide of Potassium and small doses of Phosphorus ($\frac{1}{4}$ gr.) may be followed with benefit, and Iron is always indicated.

As the disease is not generally associated with marked diminution in the total quantity of urea daily excreted, uræmic symptoms will seldom be met with, and the treatment by diaphoretics, Clutches, and purgatives will seldom be required. Dropsy will seldom require much attention, anemia being the most prominent symptom needing treatment, and the various complications of the original affection upon which the kidney disease depends.

The *circulate* form of Bright's disease will be treated upon much the same lines as the other varieties, but as anasarca and loss of albumin play so small a part in the progress of the disease, treatment in this direction is seldom required. Uræmic symptoms afford the main indication, and in the later stages of the disease the treatment resolves itself into that of uræmia, and though the progress of the affection is always towards a fatal issue when once thoroughly established, nevertheless there are few affections in which the physician can so confidently feel that he can prolong life by the judicious use of remedies to lower arterial tension and relieve the system from the dangerous accumulation of effete products by acting upon the skin and bowels. Von Noorden lays stress upon the danger of an exclusive milk diet, and recommends a fair amount of animal food and some restriction in the amount of fluids, which should not exceed about 50 oz. daily. The hypodermic injection of Saline Solution and defibrinated Blood has little to recommend itself.

Iodide of Potassium, in 10-15 gr. doses, is held to possess some specific power over the arterial sclerosis. It may be combined with Arsenic. The results of all drug treatment are, however, very unsatisfactory, and if there be any drug whose administration

will be followed by some constant action upon the pathological process or upon the increased growth of the fibrous stroma, it will be found in the Chloride of Gold in doses of $\frac{1}{2}$ gr. three times a day in pill.

Arterial tension may be lowered by small and oft-repeated doses of Nitroglycerin, but it is manifest that this treatment cannot be kept up for an indefinite time in the course of a disease of many years' duration, nor is it advisable to lower it too much. Constant purgation with Salines every morning especially with the Sulphate of Magnesia, Friedrichshall, or Hunyadi Water, may be kept up with much benefit for very long periods. In the intervals during which purgatives may be suspended and the bowels allowed to rest Nitroglycerin or Nitrites may be given, and Hot Air Baths or Hot Packs at night.

It is needless to say that the causes of the disease should be removed, and, at the earliest possible moment, chronic alcoholism, lead poisoning, and gout be actively dealt with.

Upon the first appearance of dangerous uræmic symptoms, the physician should purge rapidly, employ the Hot Wet Pack, and give Pilocarpine by subcutaneous injection, and try the Nitrite of Amyl or blood-letting.

BROMIDROSIS.

The treatment of fetid perspiration, chiefly of the feet or armpits, but especially of the former, is a matter of importance, as the victims are almost outcasts owing to the extremely unpleasant odour arising from them. The most scrupulous cleanliness must be rigidly enforced, and the general health carefully attended to. Internal remedies are of little use, though Belladonna or Atropine internally has some influence upon the secretion of the sweat, and may be combined with Ergot; or 20 grs. of Boracic Acid three times a day, along with 20 grs. of Precipitated Sulphur morning and night, may be tried.

The best local treatment by far is powdered Boracic Acid rubbed into the skin and dusted freely between the toes, and generously strewn over the inside of the stockings and boots and repeated twice a day or oftener with change of stockings. Cork inside soles should be worn and changed from time to time, or dipped into saturated Boracic Acid Solution and allowed to dry. Stockings may be treated in the same way with advantage. Shoes or boots with cloth tops, are to be worn, and the feet should be kept as cool as possible.

This treatment carefully carried out will, in the great majority of cases, effect a cure if persisted in. Strong Boracic Ointment may be used instead by those who have long walks to accomplish.

Bardet uses the following powder, sprinkled inside the stocking soles, after washing the feet and rubbing with Alcohol:—

Pulv. Talers, ʒss. Bismuthi Subnit., ʒss.; Potassii Permang. ʒij; Sodii Salicyl., ʒss.; misce.

Pringle recommends:—Sodii Salicyl., 15 grs.; Bismuth. Subnit., 30 grs.; Pot. Perman., 80 grs.; with Creta Prep., 6 drs.

Sponging the feet over with the Tincture or Liniment of Belladonna is useful, and Hebra used the Diachylon Ointment (melted diachylon plaster, mixed with an equal weight of linseed oil), spread upon strips of linen and applied morning and night. In a few days the thick cuticle exfoliates, leaving a healthy skin below. After this has come away, astringent dusting powders effect a cure in a few weeks.

A strong spirituous solution of Quinine and a 6 per cent. aqueous solution of Zinc Chloride have given good results.

Weak Corrosive Sublimate Solution has been tried, and solution of Salicylate of Soda, Oxalic Acid, Naphthol, and Boroglyceride have given good results. Unna uses an ointment consisting of equal parts of Zinc Ointment, Turpentine, and Ichthyol and dusts in a powder during the day composed of 15 grs. powdered Mustard and 1 oz. Talc. Kaposi applies a solution of 24 grs. Naphthol, 48 m. Glycerin, and 1 oz. Alcohol, twice a day, and afterwards dusts on 16 grs. Naphthol, mixed with 3 oz. Starch Powder. Formalin painted over the sole of the foot is recommended by Gerdeck.

Where the excessive and unpleasant sweating of the feet is associated with the formation of ulcers and abrasions, the dry Boracic Acid will often effect a cure, but the use of a 5 to 10 per cent. Solution of Chromic Acid as a preventive before ulcers break out was adopted in the German Army for tender feet. The writer has seen trouble follow the use of this solution in cases where blisters or ulcers had already formed, and several cases of serious poisoning from the absorption of the acid are reported. A 2 per cent. Ointment of Salicylic Acid is now used in the German Army, and Tannoform is likely to take its place.

Neebe's method is reported to give most satisfactory and lasting results. He places the soles of the feet and heels in crude Hydrochloric Acid for ten minutes, taking care not to let the acid come in contact with the dorsum of the foot. As soon as pain is excited the immersion is stopped. The skin, especially between the toes is then carefully washed in soap and warm water. Applications are repeated twice weekly for five to eight weeks. He holds, after fifteen years' experience, that the most obstinate case of sweating feet can be cured with a quart of crude Hydrochloric Acid, and he has found that chronic catarrhs even of the stomach disappear as soon as the feet are cured. Where the patient refuses to use the strong acid, he employs daily a 10 per cent. Argent. Nit. solution, and he is satisfied that any drug which will produce complete exfoliation will give satisfactory results.

BRONCHIECTASIS

Will be best treated by attention to the general health and the judicious use of remedies indicated in wasting diseases, as Cod

Liver Oil, Malt Extract, or Hypophosphites, change of climate, sea voyage, and the use of remedies applicable to chronic bronchitis, especially the Iodide of Potassium.

Creosote holds the first rank as an internal remedy, and is indicated in both forms of the disease, whether the enlargement or dilatation of the bronchi be general or only confined to one or more saccular or cavernous dilatations. It is in the latter variety that the greatest difficulties in treatment present themselves. The pus or muco-purulent discharge lying in these cavities becomes very fetid, and can only be reached in many instances by remedies eliminated by the bronchial mucous membrane. Two or three minims of Creosote, 3 or 4 times a day in mixture or capsule, sometimes give excellent results, especially when the cavity is basilar. Oil of Sandal Wood, Oil of Eucalyptus, Eucalyptol, Guaiacol, Thymol, Tar, or Terebene, can be given upon the same principle. Myrtol, in capsules containing 2 minims, four times daily has also been given.

All these volatile antiseptics are, however, inferior to Garlic as recommended by Poore. The drug must be given in large doses along with or after food in cachets containing half a tea-spoonful of chopped Garlic, so that the odour of the drug in the breath is always evident. Allyl Sulphide—the essential oil—is still more efficacious, but even in 1 minim capsules it is too irritating to be borne.

Inhalations are indicated, and Creosote stands first upon the list. Chlorine, Iodine, Menthol, Eucalyptus, Carbolic Acid, Terebene, Thymol, or Oil of Peppermint may be given as an inhalation with hot water, or placed in any of the respirators made for the purpose. It is a good plan to saturate the air of the patient's room with the vapour of Turpentine or of the Oleum Pin Pumilio or Oleum Krumholz. Any of the above-named antiseptics may be administered in the form of spray with advantage.

Chaplin has drawn attention to the great value of the vapour of Coal Tar Creosote in fetid expectoration. He employs the commercial article obtained by distillation from coal tar. When heated to near boiling point it gives off dense pungent vapour which excites coughing. The residual fetid secretion is entirely removed by exposure in a small chamber to this vapour for $\frac{1}{2}$ to 1 or 2 hours. The eyes must be protected and the various details necessary in carrying out the treatment, which has given results obtainable by no other method, will be found in his excellent paper in the "British Medical Journal," June 22nd, 1895. Ewart testifies to the great success of this treatment and emphasises the value of the coughing which goes on in the chamber, as by this means all the fetid discharge is squeezed out of the cavities. In four to six weeks often the expectoration entirely ceases and many permanent cures result.

Chloride of Ammonium in the nascent state, formed by

sprinkling salt upon strong vitriol, placed in vessels alongside those containing strong ammonia, is a valuable method of treatment, and the patient can be kept living in a room impregnated with the nascent fumes for long periods.

Where there is one large cavity, especially if near the middle or base of the lung, which cannot be reached by inhalations and which the patient cannot empty by severe coughing, the propriety of making a free opening from the outside, and establishing thorough drainage, especially if the physical signs show that it is near the surface of the lung, is established, though on the whole surgery has failed in this disease.

Encouraging results have followed the injection into the trachea of 5 grs. Menthol and 2 of Guaiacol, dissolved in a teaspoonful of olive oil, twice a day, care being taken to secure the flow of the oil in the direction of the cavity by arranging the patient's posture. This method is now practically rendered unnecessary by Chaplin's treatment, and the same may be said of the dangerous plan of injecting disinfectants through the chest walls.

The writer has found in several cases that the patient may be made to empty the cavity by lying in bed, and almost inverting his body by bringing his head near to the floor, supporting the weight of his trunk upon his hands, which rest upon the floor. The pus sometimes flows out in a stream from the mouth on assuming this position. Some patients in stooping to tie their boot-laces discover this plan for themselves. It is a good plan to have a flannel binder, moistened with Oil of Eucalyptus, placed round the chest and abdomen; the odour of the oil is given off slowly all day, and is inhaled by the patient constantly.

BRONCHITIS, Acute.

The mild cases of acute catarrh, involving only the larger divisions of the bronchial tree, require little treatment. Where the patient persists in going about and attending to his ordinary duties, the physician should be careful not to prescribe the remedies indicated where the affection is more severe and where the patient is confined to his room. Thus diaphoretic remedies, sprays, and inhalations render the patient more susceptible for the time, and should he expose himself immediately afterwards, a mild attack of bronchial catarrh may be converted into one of capillary bronchitis. A hot bath at bed-time, followed by a large Mustard poultice and one dose of Morphine, $\frac{1}{2}$ gr., upon lying down, will give relief during the night and sometimes will shorten the attack. For administration during the day, 5 minims of Liquor Morphine and 10 of Vin Ipecac. may be given every few hours. Attempts to abort the attack upon the first appearance of nasal symptoms by large doses of Quinine, Morphine, Carbolic Acid, &c., or by snuffs and sprays are generally useless.

Where the attack, though limited to the larger bronchi, is much more severe and is ushered in by some feverishness and dry, harassing cough, with sense of constriction and rawness in the chest, or where the affection is bronchitis of the middle-sized tubes from the first, the patient must be confined to his bed or to his room, which should be kept at an even temperature a little over 60° F.

The air should be rendered moist by the vapour of hot water. For this purpose the ordinary bronchitis kettle placed upon the fire is best, or a few feet of tin tubing attached to the spout of any kettle will do. The numerous petroleum and spirit lamp contrivances so much used should be strongly condemned. The unwholesome products of combustion escaping into the confined air of the room aggravate the cough, and add to the bronchial irritation. It is not an unusual event to find the cough cease when they are discontinued. Plenty of warm drinks should be administered, and there is nothing more grateful than home-made lemonade mixed (just before being swallowed) with kali water, the resulting Citrate of Potash formed by the combination being one of the most valuable of diaphoretics and expectorants, or the following mixture may be prescribed :—

R. *Pol. Bicarb.* *ʒj.*
 Tr. Aconit. *min xxx.*
 Aqua *ʒxii. misc.*

*Caput cochlearia duo magna cum cochleare uno magno
 suet limonis quarta quaque hora.*

At this stage the chief indication is to combat the dry, swollen, and congested condition of the bronchial tubes, or, as Sir Andrew Clarke put it, "to cause the tubes to sweat," and there is no remedy equal to small and repeated doses of Tartar Emetic. These may be administered after the first 24 hours, and are combined with Morphia to great advantage thus —

R. *Antim. Tart.* *gr. i.*
 Liquor. Morph. Tart. *ʒii.*
 Vin Ipecac. *ʒii.*
 Aqua Camph. *ad ʒvj. misc*

Fiat mistura. Sumat cochleare mag. tertia quaque hora.

A large poultice of Linseed and Mustard should be applied to the front of the chest to cause thorough redness of the skin, and when it becomes so irritating that it can no longer be borne with comfort, it should be replaced by a layer of warm cotton wool, and another poultice of the same kind applied to the back of the chest.

Where there is much dyspnoea, the poulticing may be continued throughout by applying plain Linseed poultices every 2 or 3 hours after the Linseed and Mustard have caused redness.

In the case of children the same treatment may be carried out, only Morphia or Opium should not be given. The little patient will, however, bear almost as large a dose of Antimony and Ipecac. as an adult. For a child two years old the following may be given in tea-spoonful doses every 2 hours :—

R *Vini Antim.* ʒj
 Vini Ipecac. ʒij.
 Aqua Ammon. Accl. ʒiv.
 Syr. Tolu. ʒiv.
 Aqua ad ʒii. *misce.*

The action of the expectorant is assisted by a hot bath beforehand. A smart purge is of use, and in gouty subjects affords marked relief. A tea-spoonful of Rochelle Salt for children, preceded by 1 or 2 grs. of Grey Powder, and in adults a 5 gr. Blue Pill, followed by a couple of wine-glassfuls of Friedrichshall Water, may be given.

Under this treatment the harassing dry cough gives place to a moist, easy, and loose expectoration, after which the Antimony may be discontinued, and the following administered in tea-spoonful doses after meals :—*Pot. Iodidi*, 1 dr. ; *Vini Ipecac.*, ʒ drs. ; *Spt. Chlorof.*, ʒ drs. ; *Inf. Senegae ad* 4 oz. ; *misce.* Or, *Ammon. Carb.*, 1 dr. ; *Spt. Ammon. Arom.*, ʒ drs. ; *Aquæ Chlorof.* ad 6 oz. ; *misce.* A table-spoonful, with water, every four hours.

Ammonia may also be given in the first stage of the affection with advantage, if there be any indication for a stimulant. Should the cough appear to be out of proportion to the amount of expectoration present, it can be allayed with anodynes, but no greater mistake can be made by the physician than simply to order Morphia or Chloral to quiet cough when the tubes are filled with secretion. In young and also in aged patients this practice will be followed by fatal results. It checks the expectoration, and renders it more tenacious ; at the same time sensibility being diminished, the cough does not occur, and the secretion gathers in the tubes.

Murrell gives 5 gr. doses of Terpene Hydrate in combination with Tar Syrup and flavouring ingredients, and Ringer advocates Tincture of Belladonna in 10 min. doses.

CAPILLARY BRONCHITIS.

Where the inflammation of the bronchial tubes has extended as far as their finest divisions, the physician will find himself face to face with a very grave malady. Here, in addition to warmth in bed and steam inhalations and poultices, Morphia must be most

cautiously exhibited, if given at all, and in the old or very young it must be withheld altogether.

As in the milder form Antimony should be given at once and in larger doses, and it should be combined from the beginning with Ammonia, and given every two hours till the dry and swollen condition of the tubes is remedied.

R. *Vin. Antim.* ℥iv.
 Spt. Ammon. Aromat. ℥i.
 Spt. Chlorof. ℥iv.
 Aqua Ammon. Acet. ℥ii.
 Aqua ad ℥viii. *misce.*

Fiat mistura. Capiat cochleare i. mag. secunda quaque hora.

Tinctures of Belladonna and Benzoin Co. in equal quantities (1 dr. to 2 drs.) may be inhaled every few hours with the vapour of boiling water. Succus Conii may be similarly employed. Should there be much pulmonary engorgement, blood-letting may be called for, though this will be seldom, but in suffocative cases the physician should not hesitate to open a vein in the arm. Leeching is useless, but relief will be obtained by dry cupping over the front and back of the chest, and sometimes a Cantharides blister will be called for. Ewart advocates mechanical aiding of the expiratory act by the pressure of the attendant's hands placed over the axillary bases of the lungs at the end of the expiratory act. Alcohol with Ammonia and Digitalis must be given where symptoms of cardiac failure are showing, and a hypodermic injection of 5 mins. of Liquor Strychnine may be given 2 or 3 times in 24 hours.

Much benefit may be obtained sometimes by the judicious use of sprays.

Apomorphia is a drug of great power, and, pushed to the verge of vomiting, it speedily causes abundant secretion of thin expectoration. By the mouth it can often be taken in doses up to $\frac{1}{4}$ or 1 gr. without causing vomiting as pointed out by Murrell. Should relief to the breathing and cough not be obtained by these measures, vomiting should be established by the use of a nauseating expectorant. Two drachm doses of *Vin. Ipecac.*, $\frac{1}{4}$ gr. Apomorphine, or 1 gr. Tartarised Antimony should be given, followed by copious warm drinks till vomiting supervene. $\frac{1}{16}$ gr. Apomorphine will be certain to cause profuse vomiting in strong adults, if given hypodermically, in 5 to 10 minutes or less. Half this dose is sometimes sufficient.

The treatment by emetics, seldom required in adults, must be a part of the management in every case of severe capillary bronchitis in children, and the physician should see that vomiting occurs

twice a day or oftener, Vin. Ipecac. being the best remedy. The act of vomiting in young children is not followed by the depression observed in adults, but it should never be allowed to cause serious prostration. Young children should be awakened up occasionally, and caused to cough or vomit to prevent accumulation of mucus in the tubes and collapse of the lung.

Alcohol or Wine Whey should be administered in proportion to the debility present, and alcohol given in warm drinks is a valuable expectorant at this stage, and is absolutely necessary in acute bronchitis in the aged and in very young and delicate children.

Inhalation of Oxygen is of the greatest value in all cases, and numerous reports in late years prove that life may often be saved by it, especially in the very old and the young, but in severe cases at all ages it may be safely employed, a small amount of the gas being allowed to mix with the air near to the patient's mouth for half an hour at a time. (The writer, in 1874, treated a patient by inhalations of Ozone.) Oertel recommends the inhalation of Cold Air.

In acute bronchitis in patients suffering from valvular lesions, Digitalis in full doses, combined with Ammonia or Ether, is indicated from the start.

R. *Tinct. Digitalis* ℥ii.
 Spt. Ammon. Aromat. ℥j.
 Spt. Ethers ℥iv.
 Spt. Chlorof. ℥ii. *musce.*

Enl. mistura. *Signs.*—"A tea-spoonful in a small wine-glassful of water every three hours."

"Tincture of Lobelia—a dangerous remedy in the weak, or in those suffering from heart troubles—may be given in 15 minim doses if there is much bronchial spasm. Many authorities recommend Belladonna, though the writer has seen little benefit from it; it is liable to dry up the tubes, but it is safe if emetics are freely administered at the same time.

Turpentine, in 30 minim doses, is a powerful expectorant and stimulant in cases where the depression caused by Antimony and Ipecac. is an element of danger.

Pilocarpine often increases the expectoration rapidly, but it must be given with caution, as it may cause pulmonary edema.

Bryonia, *Actea Racemosa*, *Kermes Mineral*, *Cocillana*, *Sanguinaria*, *Muscarn*, and many other drugs are recommended as expectorants in the early stages of acute bronchitis. It is wiser for the young physician to select the older remedies—Tartar emetic, Ammonia, Ipecac., &c., whose values are established by long experience. By closely watching the effects of these agents,

he will soon find that by varying the dosage and intervals between the doses, he can accomplish almost anything with any one of them.

After a few days the expectoration will become "loose" and more abundant. It will now be wise to stop the Tarlar Emetic, and give a little Ipecac. and Squill with Ammonia.

Spt. Ammon. Aromat. ℥vj.

Syr. Tolu. ad ℥iii. *misc.*

Fiat mistura. Capiat ℥i. *quater in die ex aqua.*

Apomorphia in small doses, \mathcal{A} gr., may be continued all through the attack with advantage.

Iodide of Potassium, at a later stage, is the best drug we possess, and Chloride of Ammonium may be combined with it in Senega Infusion.

The diet should be of the most sustaining kind—Milk and Whiskey, with strong Soups, Beef Tea, Beef Juices, and Essences given in small doses at very short intervals, oysters, fish, and farinaceous foods. Everything that interferes with the free play of the diaphragm must be watched, and flatulence and constipation corrected. Sleep may be urgently needed, but Opium and Morphia should not be given. Chloral, in small doses, often soothes cough and promotes sleep, but its effects upon the heart must be watched. Paraldehyde (1 drachm) or Sulphonal (30 grains) will be valuable, but the patient should not be allowed to sleep long at once.

In children, collapse of the lung, as evidenced by signs and symptoms, must be met by vigorous treatment till the shallow breathing, lividity, and drowsiness pass off. The patient should be plunged into a bath of hot water to which mustard has been added, and afterwards treated by a dash of cold water till free and deep respiratory movements take place.

Artificial respiration may be kept up, and a weak, interrupted current, if at hand, will do good. Afterwards free stimulation with Ammonia, and small doses of Brandy, with smart snapisms to the chest wall, and a limited allowance of sleep at one time, will be the best means to meet the collapse.

Quinine, so much recommended in acute bronchitis, and even in the serious complication just mentioned, is, according to the experience of the writer, a mistake. He has frequently seen marked embarrassment caused by the action of one large dose in drying up the expectoration and rendering it adhesive and

difficult to be expelled. Musk may be given with advantage in such cases.

Sir William Gardner has philosophically worked out the complex problem of the action of expectorant remedies, and has arrived at the conclusion that expectoration is far more dependent upon the expulsive mechanism of the muscular fibres than upon alterations in the amount or consistency of the secretion. To these muscles he gives the name of "scavenger muscles" of the respiratory tract, as they perform for the lungs and bronchi the same service as the intestinal peristalsis in the case of the digestive tract. He, therefore, urges that in the treatment of bronchitis, the so-called expectorants should be prescribed as excitors of the bronchial peristalsis, in the same sense as cathartics are excitors of the intestinal peristalsis, or as ergot is an excitor of the uterine action. This action is, in his opinion, to a great extent independent of vomiting, and also even independent of change in the density and adhesiveness of the expectoration. See Rossbach's views in the author's "Materia Medica," 7th Edition, page 330.

BRONCHITIS, Chronic.

Treat the cause, if possible. Thus, if dependent upon the inhalation of foreign particles, the patient must change his environment and any occupations necessitating the breathing of a dusty atmosphere. If the patient's means permit, removal to a warmer and drier climate is necessary. If gout be the cause (this is frequently so in dry catarrhs), this malady will require careful attention. Should the chronic catarrh be caused by long-standing congestion of the bronchial mucous membrane, the result of valvular lesion or cardiac failure, much can be done by strengthening the heart and improving the circulation. In those cases where faulty elimination of effete matters by the kidney appears to aggravate bronchial trouble, the treatment for chronic uræmia will give relief. The presence of emphysema will be an indication for tonics and measures directed to the maintenance of the general health. The physician endeavours, when the case is not of very long standing, to act upon the bronchial mucous membrane, so as to modify or alter the diseased action.

Iodide of Potassium, Arsenic, and Iron, alone or combined, are very useful for this purpose, and there is the further advantage in employing Iodide of Potassium that it is one of the best expectorants, rendering the sputum more liquid and remedying its tenacious or adhesive quality, and it is the very best drug for bronchitis associated with difficulty of breathing or asthma.

Various methods of employing inhalations of compressed air have been employed, but on the whole this method of treatment has not gained ground of late years.

Should the cough be dry and the efforts at expectoration difficult the physician will have to satisfy himself, by close

examination of the symptoms, whether the patient is not coughing much more than is really necessary to get up the expectoration. This is a point of vital importance in the treatment of chronic bronchitis. Upon the decision arrived at will depend the administration or prohibition of sedative remedies. By checking the cough much good will be done, if this cough can be seen to be useless, but if, by checking cough, expectoration accumulates in the tubes, much harm may result. Morphia or Opiates should therefore, in the chronic as in the acute disease, be administered with great caution, and if the physician is in doubt he should order only small doses, to be suspended if lividity or drowsiness appear, and by prescribing a stimulating expectorant along with the sedative the minimum of risk is encountered.

Given, then, a case of dry catarrh, with much difficulty and little expectoration of a thick adhesive kind, the best treatment will be a mixture like the following —

R Potassii Iod. ʒj.
Pot. Bicarb. ʒiv.
Ammon. Chloridi ʒii.
Liquor. Morphia ʒi.
Aq. Chlorof. ad ʒviij. misc.

Fiat mistura. Signa—"A table-spoonful 3 or 4 times a day."

Or, Apomorph. Hydrochlor., 2 gr.; Codeine, 3 gr.; Vini ʒss 6 drs; Glycerin et Aquæ ad 3 oz. Misc. One tea-spoonful every three hours.

Heroin, the new substitute for Morphine is much praised as anodyne where the patient is coughing much more than necessary. The dose is about $\frac{1}{16}$ grain.

Alkaline Salts have the power of diminishing the viscosity of expectoration and hence the value of various mineral waters. Where from any cause there is fever present, as in bronchitis attacks in phthisical patients, there is no combination given relief as a solution of Bicarbonate of Potash in effervescence of Lemon Juice, the Citrate of Potash being a valuable expectorant. Five drops of Morphia solution may be added to each dose. (formula upon page 96.)

In cases of chronic bronchitis, associated with profuse purulent or muco-purulent expectoration, morphia or other sedatives are to be administered, for, as pointed out by Burney Yeo, remedies are indicated which have a specific action upon the inflamed membrane, and to this important class belong all the vegetable expectorants and those containing some active ingredient extracted by the bronchial surface — Ammonia, Ammoniacum, Asafoetida, Balsams of Peru and Tolu, Copaiba, Creosote, Guaiacol, Petroleum, Cubebs, Eucalyptus, Sulphur, Garlic, Tar, Terebene, Turpentine.

Myrtol Camphor, Terpene Hydrate, Terpinol, Oil of Sandal Wood, and many others.

It is impossible to enumerate the special indications for each particular expectorant; unfortunately, we do not know the class of case in which some will fail and others will succeed until we try and occasionally the physician will find himself combining several in one prescription.

Tar is about the best member of the group. It may be given in capsules, pills or mixture, emulsified with suitable excipient, but Tar Water (1 to 10) taken in a wine-glassful to half-pint doses, is the least elegant, but most efficacious, preparation. Ringer and Murrel found 2 gr. pills every three or four hours most efficacious in winter cough and bronchitis with profuse expectoration. Yeo advises inhalations of Tar by forming a spray of the water by means of a Siegle's spray producer, and he adds 10 per cent. of Carbonate of Soda to good ship's Tar, to neutralize the irritating pyroligneous acid and boils the mixture on a plate over a spirit lamp in the patient's room for fifteen minutes once or twice a day.

Creosote may be given in capsules, and the internal administration supplemented by inhalations, fumigations, or sprays. It is the best remedy where there is any trace of fetor in the expectoration. There are few routine remedies which give better results than a course of Sulphur when taken alternating with Cod Liver Oil.

For the chronic bronchitis of the aged, Ammoniacum is a most valuable expectorant. It relieves wheezing and promotes expectoration and the writer obtained splendid results in a large infirmary of aged invalids with the following inelegant stock mixture:—

R Ammon. Chloridi ℥i.
 Lin. Camphoræ Ammon. ℥j.
 Mist. Ammoniaci ad ℥xxx. misce.

Fiat mist. Capiat ℥ss. quarter in die ex aqua, p.p a

The ingredients in the camphor liniment are very valuable in this formula.

Terebene, in doses of 10-15 minims in capsule or upon sugar is a good remedy in winter cough and in bronchitis with emphysema. It may be used as an inhalation.

Oxillana, Squill, Senega, Ipecacuanha, Actæa, Lobelia, Serpentaria, Cheek, Grindelia, Hydrastis, Physostigma, Sangunaria, Stramonium, Hyoscyamus, and Belladonna have been all tried with success from time to time in the treatment of chronic bronchitis. Most of them have already been referred to under acute bronchitis. The favourite remedy in the chronic and relapsing attacks of bronchitis in childhood, and the most convenient and safest, is a mixture of equal parts of Wine of Ipecac and Syrup of Squill for a child 1-2 years old, 10-15 drops every 3 hours, and as an emetic 1 tea-spoonful. There is

perhaps no combination or mixture so universally used as the following in chronic bronchitis with emphysema. Patients stick to it for years after discarding all others. Perhaps it owes its virtue chiefly to the Ammonia contained in it.

R. *Ammon. Carb.* gr. lxxx.
 Tinct. Camph. Co. ℥vi.
 Tinct. Senega ℥iv.
 Infus. Senega ad ℥viii, *misce.*

Fiat mistura. Capiat cochleare magnum quater in die ex paululo aque.

Strychnine, by stimulating the respiratory centre, becomes a valuable expectorant. It may act also, according to Gardner's theory, by stimulating the "scavenger" muscles and increasing the activity of the expulsive mechanism in the bronchi. It may be combined with Belladonna with great advantage where there is much secretion and *weakened expulsive powers*.

Though the list of expectorants contains more than 100 remedies of undoubted value, the physician will find that most of the cases of chronic bronchial trouble can be well combated by one or more of the following list, beyond which the writer seldom finds it necessary to travel.—Apomorphia, Alkalies, Ammonia, Tur, Ipecac., Creosote, Pot. Iod., and Senega.

Cocillana has recently been used as a substitute for Ipecacuanha, in doses of 5-8 minims of the fluid extract. Ichthyol in 10 gr. doses three or four times a day, in gluten capsules, is strongly recommended by Le Tanneur.

For chronic bronchitis with *exceedingly* profuse discharge, i.e., cases of bronchorrhœa, an occasional emetic and full doses of a mixture of Ammoniacum, Ammonia, and Senega afford the best treatment. Copiaba is a valuable drug in some cases; it may be given in capsules or in a mixture with Liquor Potassæ, or in the form of the paste mentioned under Gonorrhœa. Opium or sedatives are fatal if given in even fair doses.

Reference has already been made to the use of sprays and inhalations in chronic bronchitis. As a rule, it may be said that too much reliance should not be placed upon their use, and many maintain that they are useless. Ringer and Murrell have obtained excellent results from a spray of Vin. Ipecac. in winter cough. This spray is used by atomising the ordinary Ipecac Wine with a Richardson's apparatus or with a steam atomiser; generally the wine does best diluted with an equal bulk or more of water. About two drachms of the wine are sufficient for each sitting, and after a few trials the patient succeeds in taking it in deeply.

Lobelia, Terebene, Pinol Antimonial Wine, and Iodide of Potassium, 2 per cent. solution, have all given excellent results in chronic winter cough.

Fluoride of Ammonium Inhaler is of undoubted value, in cases of chronic catarrh of the trachea, larynx, and bronchi. It is, however, far inferior to the method of a sick room with the fumes of the nascent salt as upon page 94.

Thus, Carbolic Acid, Creosote, and most of the volatile oils and antiseptics, are of value when administered as such, especially where there is marked fetor or decomposition of the bronchial secretion.

The volatile drugs can be used as an inhalation, by simply adding them to boiling water and then inhaling their vapour in connection with the steam given off by the water. Compound of Benzoin is the most frequently employed.

Water has had great satisfaction with Turpentine. By saturating the air of the room with it, much good can be done in chronic bronchitis, and if hæmorrhage be present there is no equal to it. It can be poured upon the surface of hot large open vessels, placed about the patient's bed.

Antiseptic volatile expectorants may be placed in a respirator for hours during the day. The following is a good one:—Thymol, half a part; Carbolic Acid and Creosote, of each one part; Spirit of Chloroform, four parts.

Sum Pini Pumilio is an agreeable and efficient alterative and expectorant when inhaled.

Friction is of value in chronic bronchitis, and it may be assisted by Iodine, Acetic Acid, Croton Oil, Capsicum, Mustard, Tartar Emetic Ointment, or the actual cautery is practised in France, or any other irritant, but as a general expectorant, which are also revulsives, are very inferior. Thus the Lin. Tereb., or Lin. Tereb. Acet., or any other application, of which the following is a modified one may be employed:—

Spl. Tereb. ℥iii.

Acid. Acetici ℥xii.

Om. Vitellum i.

Ol. Limonis ℥j.

Aque Rose ad ℥vj. *mixe.*

Unimentum.

Use of Eucalyptus or Pinus Pumilio with Camphor may be

one of these applications lies (1) in their revulsive action; friction assists the expulsive efforts, and dislodges the mucus; (2) the vapour clings to the skin and clothes, and is gradually inhaled; and (3) a minute trace

also is absorbed through the unbroken skin, and re-pulmonary tract through the blood.

Massage, or manual compression of the chest and abdomen, is useful where, owing to bronchial dilatation, or weakness in the expiratory apparatus or muscular accumulations of secretion are liable to occur.

Where the patient's means afford it, there will crop question of a suitable winter residence, and a sojourn at a Continental Spas, where the free use of alkaline water is tried, as at Braun, Soden, Ems, Mount Doré, &c., or any home where natural sulphur water may be had, as Harrogate (the summer). Abroad, Camberley, Lichon, and Aix-les-Bains are highly recommended. If the patient finds that a warm climate suits his breathing, he may go to Mentone or San Remo. If a still drier atmosphere is desired, Egypt or the Nile. A Tangiers will be best. Should, however, a soft or sedate climate be desired, Madeira, Pau, Torquay, Penzance, Bournemouth, or Wight may be recommended. Your remarks that "the best for the majority of patients is Madeira, and it is accessible by the fast Cape steamers in three days and a few hours."

Bronchial irritation in young subjects, where the super-tubercular phthisis is feared, will be well treated by a residence at the pine forests of Arcachon, or nearer Bournemouth.

BRONCHOCELE—See Goutte.

BRUISES,

If seen early before discolouration has already occurred, best treated by the application of cold. Ice or evaporated Lotion is the most effectual. A cold saturated, recently prepared solution of Chloride of Ammonium is a good application to contusions where a "black eye" is dreaded. The juice of the root of *Convallaria* (Solomon's Seal) is reputed to be of good use for the same purpose. *Arnica*, so much recommended for this purpose, should be used with extreme caution. It is of little value, and often produces dangerous erythematous rash may spread from the site of application over the entire body.

Should extravasation of blood or ecchymosis already have taken place, warm Spirit Lotion, covered with oiled silk, and covered over with thick layers of cotton wool, and bandaged tightly, will do more than anything else to cause absorption of blood. The surgeon should be very slow to incise the skin, even extensive extravasations of blood have occurred; if left in rule, if let alone, will become absorbed in a short time, admission of air is fraught with great danger. The ointment may, however, be safely used where the removal is necessary. Careful Massage, Capsicum, Camphor,

pressure, and mild counter-irritants may be afterwards used to hasten the process. Pain is best relieved by Opium, Aconite, Belladonna, or Acetate of Lead.

The application of Leeches occasionally prevents discolouration, if used very early, but they are upon the whole of doubtful value.

ECCHO.

Confining the term to an indurated and often suppurative condition of the glands in the groin, secondary to a venereal sore on the penis, the first treatment should be directed to the sore itself and all irritation or inflammation in it should be at once attended to. If the bubo is only in the early stage, it may be prevented from suppurating by freely painting the skin over it with very strong solution of Nitrate of Silver, or by moistening the skin and rubbing with the solid Nitrate. Absolute rest to the part is essential.

Saturated solution of Iodine, in spirit, may be applied. Berkley Hd. sometimes caused the abortion of buboes by the pressure of a pad of wool and an elastic bandage. The writer has obtained excellent results by painting the skin over the enlarged gland with Iodized Phenol (Iodine, 1 oz.; Carbolic Acid, 4 oz. or using ice and evaporating lotions; Leeches are of doubtful value as their bites may become the source of new inoculation by the pus afterwards finding its way into them.

The heroic method of injecting Carbolic Acid or of applying Blisters, followed by Iodine, is not to be advocated. Wielander injects 15 minims of a 1 per cent. Solution of Benzoate of Mercury into the bubo, and follows this by compression. He claims 90 per cent. of successes from this abortive treatment. The state of the patient's general health should be narrowly examined, and emetics, aperients, and liberal diet, with a change to the sea air, if possible, in bad cases, may be necessary. If matter has already formed in the gland, temporising can only do harm. Arrangements should at once be made (a) to completely excise the gland and any others that may be enlarged. Or, (b) make a small incision into the gland and thoroughly scrape away its contents by a flushing curette and inject Iodoform Emulsion. (c) If the patient will not submit to an anæsthetic, as is generally the case, a free incision should be made, and the opening in the gland thoroughly dilated with forceps, and efficient drainage established. This operation can be painlessly carried out under Cocaine anæsthesia. It is a great mistake to wait till the skin becomes involved, as the resulting undermining of the edges of the sore is difficult to treat, except by excision with scissors. Otis treats suppurating buboes by disinfecting the skin, incising with a narrow bistoury, squeezing out the contents, washing with Sublimate Solution (1 in 1,000), and filling the cavity by injecting warm Iodoform Ointment 10 per cent.

The sore resulting from ulceration or incision may be swabbed out with Corrosive Sublimate Solution (1 in 500) or Iodized Phenol,

and dressed with Spirit, Lead, Carbolic or Chlorate Lotion, or dusted over with Iodoform.

Should healing be very slow or indolent, a light brush over with Nitric Acid or Acid Nitrate of Mercury, and after-dressings of Solution of Chloral (1 in 30) or Peroxide of Hydrogen will hasten recovery. In very chronic cases the agents detailed under "Ulcer" may be used after failure of the above, but in most chronic cases there is no drug so uniformly successful as Iodoform. It may be dusted over the sore or used as an ointment (1 drachm to 1 oz.).

BUBONIC PLAGUE—See Plague.

BUNION.

The only treatment in the early stages followed by lasting benefit is to remove the cause, by insisting upon a wide-soled boot, with square, roomy toes and low, broad heels. The deformed large toe is to be drawn inwards into line with the inner border of the foot, and maintained in this position with strapping. "Digitated Socks," containing a separate compartment for the great toe, aided by a "Toe Post" in the boot, are very efficient in slight cases.

Instrument makers supply a bunion spring, but it is not comfortable. The writer has had good results with a simple piece of leather moulded when wet to the great toe, as it is held in position in line with the inner border of the foot. This is fastened on in the evening and worn till next morning.

Liment of Iodine applied daily reduces induration and relieves pain. Should inflammation have supervened, rest must be enforced and the swollen joint treated with evaporating lotion (Lead and Opium or Spirit), and if suppuration occurs, a free incision. Relief in slight cases may be obtained by wearing a neatly fitting felt plaster with a hole cut in its centre.

Another method of treating bunions has been recommended. The foot is well washed and dried, after which the healthy skin surrounding the bunion is then coated over with a layer of flexible Collodion, for protection. Carbolic Acid, in the crystalline form, is then thickly laid on over the bunion, and the superfluous acid removed by blotting paper. The applications are made every three or four days. This can only be of use in very mild cases.

When ordinary measures fail, and the deformity causes both pain and inconvenience, various surgical procedures may be tried. A simple and effective method is as follows:—A slightly curved incision is made over the bursa, and the latter completely excised. The projecting inner aspect of the head of the metatarsal bone is removed by chisel or saw, and the edges carefully rounded off, the internal lateral ligament being of course sacrificed, and the joint opened; the external lateral ligament, and if necessary the extensor tendon, may require division in order to bring the toe into position. The wound is then closed, and the toe kept in a slightly over-corrected position till union has occurred. This method has given excellent results with no noticeable deformity.

Anderson and others recommend excision of the head of the metatarsal bone. This, however, is a severe method, as it involves the removal of a very important support to the weight of the body.

Barker has successfully performed antiseptic osteotomy of the metatarsal bone through its neck; he removes a small wedge-shaped portion, fractures the remainder, and brings the toe into good position. The after-treatment is conducted upon general surgical principles, care being taken to provide efficient drainage, and after the healing process is completed, a partitioned shoe and glove-stocking afford great comfort.

BURNS AND SCALDS.

When the skin has been for a short time submitted to even an intense heat, if a saturated Solution of Bicarbonate of Soda be instantly applied, no vesication or destruction of cuticle occurs, and pain is almost instantly relieved. In this simple way, what would otherwise have been a troublesome and painful burn will be effectually prevented. But the application must be made without delay, and before the cuticle is raised, and the quickest way is to apply the dry salt made into a paste with a little water, and gently rubbed over the smarting spot for a few minutes, adding a few drops of water from time to time.

The first treatment required in the case of severe and extensive burns is to relieve the shock and collapse, and bring about reaction, by enveloping the patient in flannel or wadding and administering liberal doses of hot stimulants, whiskey punch, or wine whey—relieving pain by full doses of Opium, preferably in the form of Dover's Powder, and whilst this is being done only very limited attention can be bestowed upon the burn itself. The clothing should be carefully cut off, piecemeal, and only a limited portion of the surface of the body should be exposed at one time.

Corrosive liquids, if they have been the cause of the burn or scald, should be washed off with an appropriate solvent. Thus, scalds by boiling acids should be lightly washed with warm water or weak alkaline solutions, and boiling tar scalds may be gently cleaned with any warm bland oil or lard.

Immersion of the body in cold water after extensive burns is a very questionable proceeding, and many deaths have been caused in this way; but a burn of the first degree, affecting a limited area of the body—say one limb—may be well treated by immediately enveloping the limb in cold water dressings. Where a very large surface of the body is superficially burned and the patient is suffering great pain, relief may be obtained by immersing the patient in a bath at about 98° F.

In dealing with a burn of the first, second, or third degree, whether large or small, the first indication is to exclude the air as soon as possible; if blebs have formed they should be punctured at their most dependent parts through a small aperture—thus saving as much as possible of the cuticle as a covering to the

injured skin. One method is to dust over the entire part with a thick coating of Wheaten Flour, upon the top of which is placed a soft uniform layer of cotton wool, covered by bandages.

Should this plan be adopted the writer would suggest that the flour be mixed with some finely-powdered Boracic Acid, say 1 to 4. The practice of Ostermayer is an improvement. He uses a powder of Potassium Sozoiodol mixed with starch or talc-powder in 10 per cent. strength. It has the advantages over most other applications in being without odour and non-poisonous, and it prevents suppuration.

Powdered Iodoform is used in the same way, but it lacks these properties; it is, however, a local sedative. But it must not be forgotten that poisoning by absorption is likely to ensue if the burned surface is extensive and the antiseptic possess toxic properties.

Salol, Thiol, Bismuth, and other powders have been used alone, or with Talc or Oxide of Zinc.

Whatever will enable the first dressing to remain on for the longest possible period with safety is an advantage, and these bland antiseptics will delay putrefaction.

The list of dressings and applications for burns is practically endless. Nearly every surgeon has his own favourite. Lint or gauze soaked in a saturated watery solution of *Picric Acid* makes an excellent aseptic dressing which may be left in position for 2 or 3 days if there be no rise of temperature. It acts as a sedative and causes rapid coagulation of the albuminous fluid which oozes from the sore.

Modern surgeons object to the use of the old-fashioned Carrot Oil, on the ground that it cannot be rendered aseptic, and Cheyne speaks of it as "a filthy application." Nevertheless, as it can be prepared anywhere, on a moment's notice, it is likely that it will remain popular with the general practitioner for some time to come.

Upon each change of dressing, if suppuration has occurred the surface should be syringed with a weak antiseptic (Boroglycende, 2 oz. water, 20 oz.).

Burns of the third degree are treated by Hebra by keeping the patient in a warm bath for weeks.

The pain is somewhat relieved by Carbolic Acid, Iodoform, or Salol added to the above dressings, but when it is intense there is no remedy equal to Cocaine, and it may be applied in solution from 2 per cent., where a very large surface of the body is involved, to 5 per cent. or more in less extensive burns. It is of little use unless when the cuticle has been removed.

The free use of strong antiseptic applications may retard the separation of the sloughs, and it is especially desirable that this should not be, hence hot applications are indicated. These may be applied whilst the dressings are being changed, which must be often, by immersing the limb in a hot antiseptic lotion, Carbolic (1

in 30, Boroglyceride (1 in 20), Corrosive Sublimate (1 in 5,000), for periods varying from 10 minutes to 2 hours. Erichsen recommends that the pain caused by the daily dressing may be more relieved by immersing the patient in a bath as hot as he can comfortably bear for half an hour before removing the dressings; the bath should contain 10 drachms of Boracic Acid to each gallon of hot water.

After separation of dead tissues the granulating wound may be treated upon general surgical principles.

Much care and attention must be given to the position of deep burns, so as to counteract the tendency to future deformity after contraction.

The resulting scars are specially liable to be the seat of keloid, and this has been attributed by many writers to the prolonged use of strong antiseptics.

Where healing is slow or large granulating surfaces are left, no treatment is to be compared to skin grafting by Thiersch's method; but to be successful it requires great skill in the cutting and handling of the grafts, and the most rigid asepsis. In this way weeks or months of suffering may be saved, a firm and painless scar obtained, and subsequent deformity greatly diminished. When a limb is extensively charred amputation may be necessary.

The following are a few of the many other methods by which burns may be successfully treated —

By enveloping the part in successive layers of gauze prepared by previously soaking muslin, freed from fatty matters in an ethereal solution of Iodoform, and allowing the ether to evaporate. This appears to be a most excellent plan, and has given very satisfactory results in the hands of Moseley, who has never seen any bad symptoms follow. The free dusting with powdered Iodoform of large tracts of the surface of the body involved in burns or scalds is dangerous.

Oxide of Zinc or powdered Starch may be dusted over burns instead of flour and any harmless antiseptic may be combined with them.

Of greasy applications there is no end — Chalk or Whiting made into a paste with boiled Linseed Oil, Calamine and Zinc Ointments made thin by adding Olive Oil, Boracic Ointment, White Lead Paint, Iodoform Ointment (1 to 30 Vaseline), Carbolic Oil (1 to 20), Carbonate of Zinc Ointment (1 to 10 Spermaceti Ointment), Resin Ointment, Chalk Olive Oil and Vinegar in equal parts Cod Liver Oil, Kentsh Ointment (Lin. Tereb. U.S.P., Resin Ointment, and Turpentine). It is a good way to treat small superficial burns by applying Turpentine as soon as possible upon Lint, though the pain is at first increased it soon subsides. Pure Glycerin is an excellent first dressing, and is not painful. It is claimed for it that it prevents vesication if applied early. Salicylic Oil (1 part Acid to 50 Olive Oil), Olive Oil and Egg Yolk, equal parts;

Elemi Ointment, Olive Oil and Thymol (1 in 100). Grose extol Ungt. Gallæ and firm bandaging for severe burns.

Of liquid applications for burns any antiseptic lotion may be used such as might be applied to ordinary wounds (see under Abscess). Solution of Pot. Permang. (1 in 500) is a good remedy in the early stage, and Solution of Cocaine (1 in 50) may be painted on to relieve acute pain.

Of pastes the best are Carbonate of Bismuth and Glycerin, Oxide of Zinc and Glycerin; or Powdered Gum Arabic, 3 parts; Tragacanth, 1 part; Treacle, 2 parts; Carboic Acid Lotion, q.s.

BURSITIS.

In acute affections following injuries and wounds, absolute rest of the limb on a padded splint, and the application of cold lotions or ice, generally suffice to bring about resolution. If much pain be present, poultices smeared with Extract of Belladonna or heat fomentations may be applied, and if suppuration occur, a free incision and subsequent syringing with very weak Sublimatè Solution (1 in 5,000) will be necessary.

For the chronic affection most common in the bursa over the patella (Housemaid's Knee) the majority of cases yield to the daily application of strong Iodine liniment, applied freely (as each layer is allowed to dry it may be followed by a fresh one), so that blistering occurs.

Should this fail, the fluid may be aspirated, and if it soon collects again, a splint and tight bandage may be applied after a second aspiration. Should the fluid again collect, a few drops of strong Carboic Acid may be injected, or the fluid once more removed, and a small syringe of Tincture of Iodine and water (1 in 1) may be injected and allowed to remain in for a few minutes.

Melon-seed bodies should be removed by free incision, or, better, by excision of the entire bursa, as they are probably tubercular in origin.

Chronic enlargement of the bursa, with fibroid thickening of its walls, can only be successfully treated by excision of the entire

CANCER.

The treatment of the various forms of malignant disease by internal medication must be confined to the relief of pain, or to the amelioration of symptoms caused by the disease interfering with the functions of the organs affected.

Chian Turpentine has not been followed by any success warranting further trial and the same may be said of Chelidonium, of Thuja, and of Cinnamon, and in our present uncertainty about

the etiology of the malady there is no internal remedy which can be said to have any effect upon the progress of the disease.

Surprising results have been published by Coley, of New York, by the injection of Toxins into malignant growths beyond the reach of operation, and, therefore, absolutely hopeless. The following are his conclusions:—

1. The mixed Toxins of Erysipelas and Bacillus Prodigiosus have an inhibitory action on the growth of malignant tumours.
2. This action is more powerful on sarcoma than carcinoma.
3. A considerable number of sarcomas have disappeared under this treatment, and several of these have shown no sign of recurrence three years later.
4. The treatment involves but slight risk. Coley gives two hundred cases, with only two deaths.
5. The toxins to be of value must come from very virulent cultures, and must be freshly prepared.

Herbert Snow has recently suggested the administration of Extract of Lymph Glands.

Richei and Henicourt have reported two striking successes with the serum treatment, they used the serum from an ass and two dogs, into which they had injected the juice of an osteo-sarcoma. One case was an instance of stomach cancer with a malignant tumour as big as an orange. It disappeared in 14 days.

Berrata has reported 73 cases in which he has used the serum. The benefit appears to have been limited to slight relief of pain and slight softening of the tumour. In some instances the rapidity of the growth appeared to be delayed, but this effect was only very temporary.

Recently remarkable successes have been reported from the use of the X Rays and Finsen's phototherapy.

All that we can say at present is that early removal of the growth and surrounding tissues and lymphatics affords the only hope of cure, and though there are many who believe that operative interference or extirpation will after all but postpone the fatal issue, still there is abundant evidence that early and complete eradication of malignant growths has been sometimes followed by immunity from any return of the disease, and when the disease has returned, it is generally after such an interval as shows that its progress has been at least retarded. Every year increases the evidence of the curability of cancer, and there are few more remarkable results in operative surgery than the steady increase in the number of successes which are occurring since surgeons have realised that success depends upon early operation and complete eradication of the entire disease by cutting wide of all possible extensions in lymphatics, skin, and muscles. (See under Cancer of Breast.) Eliam goes so far as to state that "in all cases when an operation should be undertaken, the patient may almost be promised a certain recovery from it; advances in surgery have done this much."

Extirpation by the knife, though it affords the best hopes, should not be solely relied upon for one reason. There cannot be a doubt that the earlier the removal the better the prospects, and patients too often cannot be induced to submit to a cutting operation, even by the most urgent and earnest entreaties. In these cases radical application of Arsenic, Vienna Paste, Chloride of Zinc, Caustic Potash, pure Bromine, Papain, Acid Nitrate of Mercury, or the thermo- or electro-cautery may give better results at a *very early* stage than can be obtained by the knife at a later period. The writer has seen this proved upon several occasions, where patients, refusing firmly to submit to a cutting operation, have submitted to cauterisation by Arsenic at the hands of quacks with enviable results.

Trueneck and Czerny have recently revived the arsenic method of destroying malignant growths. They affirm that the cancerous cells have a specific affinity for arsenic which destroys them without injury to the healthy tissues when skilfully used. They begin by applying a mixture of Arsenious Acid 1 part in 75 parts absolute Alcohol, and 75 parts water. This mixture is increased to nearly double strength as the necrosed mass becomes thicker. Early cancers of the skin, lips, and mouth are successfully treated in this way, and in cases of sarcoma the growth dies *en masse*. A line of demarcation soon forms, and the tumour can be removed by snipping through any remaining adhesions. Griswold's method appears the best for the application of Caustic. He heats Sulphate of Zinc to dryness, pulverises it finely and makes it into a paste with pure Sulphuric Acid. In ten minutes this destroys the tissues to the depth of one-eighth of an inch, after which the necrosed tissues are scraped away and the paste again applied. The process is repeated four or five times till the disease is destroyed. It is only slightly painful, and Cocaine may be used. The injection of Acetic Acid, Nitrate of Silver Solution, Carbohc Acid, and Solution of Papain or Pepsin into malignant tumours has led to no practical benefit.

Bernhardt claims results approaching to cure in inoperable uterine cancer by injecting a 6 per cent. Salicylic Acid solution in strong alcohol, and many other reports prove the great value of this method in inoperable cancers in various other regions, pain, sloughing, fetor, and hæmorrhage often rapidly disappearing. 20 to 60 minims are injected deeply every four or five days.

CANCER OF THE BLADDER.—Removal of malignant tumours of the bladder has been repeatedly accomplished with success by Fenwick, but in the majority of cases such cannot be attempted. Relief of pain by Morphia, by the mouth, anus subcutaneously, or by injection into the bladder, should be tried, and Cocaine suppositories sometimes afford great relief, and injections of Conium, Chloral, and other sedatives occasionally give some ease. Failing this, however, a free perineal opening into the bladder, establishing thorough drainage, may give highly-valued freedom from

the agonising attempts to micturate, and may enable the patient to pass the remainder of his short life in comparative peace.

Complete resection of the bladder in the male has been uniformly fatal. At least two successful cases have been reported in women by Clado and Pawlik. The first step consists in implanting the ureters into the vagina, then the bladder is removed; finally, the vagina is closed, so as to constitute the new bladder. After several operations, Pawlik's case had an artificial bladder which could retain twelve ounces.

When the base of the bladder is much infiltrated, supra-public drainage may be carried out, and many surgeons prefer it in all cases.

CANCER OF THE BREAST.—The earliest possible removal of the whole gland, with exploration of the axilla and extirpation of every lymphatic gland to be seen or felt, is the only line of practice followed by satisfactory results.

Heidenhain has made some remarkable observations, which emphasise the great importance of removing every vestige of the disease. He investigated histologically 18 cases of primary cancer of the mammary gland. In all the cases in which there had been a recurrence, he was able to make out by microscopic examination that fragments of cancer had remained in the wound after the operation. The extension of the disease from the tumour to the surrounding tissues is invisible to the naked eye, and where he found no epithelial rays extending from the tumour to the margins of the tissues removed along with it, no return of the disease occurred. He often found that these extensions invaded the muscular aponeurosis of the pectoralis. Hence he insists upon the necessity of taking away the aponeurosis and cutting into the healthy muscle in every case where the tumour is adherent.

Gross also puts this forcibly when, after speaking of the old operation as an opprobrium to surgery, he says: "All tissues—viz., the skin, paramammary fat, the entire gland, pectoral fascia, and axillary contents—must be freely extirpated."

Halsted, Watson, Cheyne, and others now make a rule of removing the pectoral muscle in all but the very earliest cases, and it is surprising what a useful arm is left after so radical an operation.

If the case be not one in which operation can be recommended when first coming under the attendant's notice, or if the patient refuses to submit to an operation, great care must be exercised in the use of local remedies for the relief of pain. Friction or irritants of any kind must be strongly condemned, and nothing that will hasten the breaking of the skin is to be permitted. If ulceration of the skin has already occurred, the application of any weak antiseptic lotion should be recommended. The application of caustics, like Arsenic and others already mentioned, is to be avoided.

Where the local disease does not admit of complete removal

Beatson, of Glasgow, has recommended removal of the ovaries with a view to causing atrophy of the tumour. Some remarkable results have undoubtedly been obtained by this operation and it may still be worthy of trial in desperate cases. Mr Stanley Bovey has carefully analysed 54 cases in which the operation has been performed; only 19 derived any benefit, and in all of these the growth again became active in 6-12 months.

Many substances may be now used with the view of lessening pain —

Belladonna Extract, rubbed up with Glycerin; Hydrate of Chloral (5-20 grs. to 1 oz.); Carbolic Acid Lotion (1 in 30) — Conium Ointment, Cocaine Solution (1 to 5 per cent) — it may be used in the form of ointment; Galium Aparine, Hyoscyamus, Belladonna, and Stramonium leaves, made into infusion or decoction. Antipyrine (1 in 100) is recommended, but it often increases pain considerably. Fuchsin in Alcohol (1 in 300) is recommended by Dyer.

Morphine-Vaseline, recommended by B. W. Richardson, may be applied on lint wherever continuous pain accompanies the presence of a cancerous tumour with an ulcerative breach of surface. The following is the formula, the Chloroform dissolves the alkaloid — is sedative and antiseptic:—

R. *Vaselin. Purif.* ʒj.
 Chloroformi ʒii.
 Morphinae gr. iv. *misce.*

Fiat Unguentum.

With the supervention of fetor, strong antiseptics are called for — Iodoform is the best, if its odour can be tolerated. It may be freely dusted over the sloughing or ulcerated mass, or pads of Iodoform gauze may be folded over the tumour.

Perechloride of Mercury (1 in 500 to 1 in 5,000), Powdered Borax, Boracic Acid or Boroglyceride, Salicylic Acid in powder or the Soda Salt in strong solution, Creosote, Carbolic Acid, Thymol, Oleum M. Pip., Turpentine, Terebene, Aseptol, Naphthol, Pinus Pumilio, Permanganate of Potash (1 gr. to 1 oz.), Zinc Chlor. (10 grs. to 1 oz.) and a host of other antiseptics, have been found useful. The best remedy, if the ulcerating mass be very extensive, is liberal and frequently changed pads of Carbolic tow, or, should expense be a serious object, large pads of well-teased-out oakum, laid upon the surface of the tumour, and secured with a light bandage, afford the cheapest and most efficient dressing, without any lotions or other applications.

Hæmorrhage has to be sometimes treated, and, as the bleeding point is not easily seized in the midst of a fungating tumour, local hæmostatic remedies must be applied. Should the hæmorrhage be the result of general oozing, the application of some of the

foregoing antiseptics, in concentrated form, will soon cause it to cease. Thus Creosote, Turpentine or Carbolic Acid, smeared over the tumour, will relieve pain, check hæmorrhage, and destroy fetor. Powdered Alum will do likewise.

If the bleeding should be from a vessel of any considerable size—cut across by the ulcerative process—there is no hæmorrhagic to be compared with the Puff-ball *Lycoperdon Giganteum*. A small pad of the dried fungus placed over the bleeding surface, or thrust into any of the small ravines in the tumour from which blood is spouting or streaming, will almost instantly cause it to stop. (Pharmacy, Materia Medica, and Therapeutics, 7th Edition, page 50.)

CANCER, EPITHELIAL.—See Rodent Ulcer.

CANCER OF THE TONGUE.—Palliative measures are only justifiable when operative interference is out of the question. Cocaine dissolved in Glycerin of Borax, frequent applications of Carbolic lotion (1 in 100), insufflations of Boracic Acid, or the application of powdered Iodoform and Bismuth (1 in 10) to any deep ulcers, and the use of deodorising solutions may be tried.

Extraction of teeth which press upon the enlarged organ, and, in some cases, the section of the gustatory nerve will be required. Ligature of the lingual artery has been done to diminish the rate of growth.

When possible, complete removal of the organ should be attempted, unless when the disease is in a very early stage and confined to the anterior part of the organ, when the tumour may be removed by the knife, scissors, or ectaseur. Butlin lays great stress upon the vital importance of preventing septic pneumonia by keeping the mouth aseptic after the operation.

For a brief description of the operations for removal of the entire organ, see under Tongue, Diseases of.)

CANCER OF THE GULLET.—Where ulceration has not already occurred, some surgeons believe that considerable relief may be obtained by the careful and gentle passing of a tapering or oliveary bougie. The writer will be slow to do this, even for diagnostic purposes, as the slightest pressure may rupture the tube above the obstructing mass; only the most cautious and tender handling of the dilating instrument is admissible. The writer a few years ago had a patient in his wards suffering from malignant stricture of the gullet, through which he intended to pass a tube; for some reason the operation was postponed, and the following day, whilst appearing as well as usual, a large volume of blood poured from his mouth and nose, and he expired—the cancer had eaten its way into the aorta. Good results have followed this palliative treatment when the bougie has been left *in situ* for hours, and if the instrument be allowed, it may be retained in the stricture whilst food is passed through it into the stomach. The writer used bougies made of laminaria in the treatment of non-malignant stricture of the gullet as early as 1875 with success.

patient who had not swallowed anything for insertion of this appliance he was immediately half pint of milk with great relish.

When the passage of food through the narrow stricture becomes impossible, rectal feeding should. Enemata of raw eggs, peptonised food or milk creamised may be given every few hours, and the rectum blunted by the addition of a small quantity to each.

In a limited number of cases the operation of *gastrostomy* may be called for.

Kocher's method is as follows :—A vertical incision, long, commencing 1 inch below the cartilages of the larynx, and extending over the left rectus, and the fibres of the muscle are divided by a blunt director. A long conical diverticulum of the stomach is drawn out into the wound and its base sutured to the peritoneum : a second incision about 1 inch long, made at a short distance above the costal margin, the skin between the two incisions is separated from the underlying tissue by a blunt director, the pouch of stomach is then drawn under the skin, and its apex sutured to the edges of the upper wound, the lower wound is completely closed. When the pouch is formed, a small incision is made into the projected pouch, the stomach, and through this food is introduced by a catheter. The method secures a modified sphincter, and the patient is able to prevent, by use of a suitable appliance, the escape of stomach contents.

CANCER OF STOMACH.—The treatment of this disease will chiefly involve itself into the treatment of the

aceous foods, and milk must form the chief basis of the dietary. In advanced cases, rectal alimentation should be resorted to. The secret of success in this class of case is to feed continually, but in very small quantity. It is not a very unusual experience to come across cases of cancer or ulcer of the stomach, where incessant, painful vomiting has brought the patient to a miserable state of collapse, through the ingestion of even moderate quantities of solid or liquid food. If the physician orders a diet of soup and milk or peptonised milk, to be given in such a case in unlimited quantity, making it a stipulation that only one large spoonful be given at one time, the liquid may pass directly through the stomach into the intestines, and all vomiting and much suffering will stop.

These directions must be literally carried out. It will not do for the patient to take in his hand a vessel of liquid food out of which he is to drink what he considers will about amount to a table-spoonful. The food must be measured in a spoon as if it were medicine.

Stimulants in liberal quantity need not be withheld, as they help the patient materially and owing to the comparatively short duration and invariably fatal termination of the affection, the alcohol habit need not be dreaded.

The best stimulant is good whiskey or brandy mixed with the milk 1 to 10. Wines, as a rule, intensify the acidity often present, though good champagne is of great use in the vomiting of the later stages of the disease.

In some cases where the pyloric symptoms and signs are well marked, careful washing out of the stomach by the funnel and India-rubber tube is often followed by great relief. For the treatment of pain and vomiting see under Gastric Ulcer, where the various agents used for this purpose are detailed, but the chief remedy is to be placed in Bismuth, combined with Morphia and Hydrocyanic Acid, Ice, and counter-irritation.

Digestives, like Pepsin and Papain are indicated where there is no reason to believe that an ulcerating surface exists in the mucous membrane. Where there is marked deficiency of free Hydrochloric Acid in the stomach, this drug can be supplied with the Pepsin.

Brissaud, of Paris, believes that he has cured gastric cancer by large doses of 2 to 4 drs. Chlorate of Soda, and he seriously reports that melæna, hæmatemesis, tumour, and cachexia all disappeared in five cases.

The vomiting of acid and yeasty matters is best met by Creosote, 1 to 3 capsules (1 minim each) may be given three or four times a day. Hyposulphites, Sulphurous Acid, Eucalyptus, and Carbolic Acid may be given with a view to destroy the arena in those cases where there is evidence that the food is retained so long as to undergo fermentative changes. Constipation, sleeplessness, and other complications are to be treated

upon general principles. Ascites, peritonitis, jaundice, or secondary hepatic derangements are also to be watched for. Surgical interference, however, offers the only hope of materially prolonging life. To be of real benefit, it must be invoked early. Complete removal is, as a rule, impossible when a tumour can be actually felt through the abdominal wall, for under such circumstances extensive enlargement of glands and secondary deposits in the liver will almost certainly be found.

An exploratory incision under modern aseptic precautions is attended with little risk, probably not above $\frac{1}{2}$ per cent., and when a patient over 35-40 years of age suffers from gastric symptoms, which fail to respond to a reasonable course of medical treatment, say 2-3 months, it is the clear duty of the attendant to urge, and urge strongly, the necessity of having the abdomen opened.

Thus having been done further interference will depend on the exact condition found.

1. Pylorectomy where possible is to be preferred, even though the risk is considerable, as it gets rid of the disease and thus offers a good prospect of prolonging life. The mortality of this operation is still very high, not less than 20-25 per cent. At least 2 cases are on record which lived 8 years after operation, and several over 4 and 5 years—results which cannot be expected after any other method. The pyloric tumour is drawn out of a vertical wound, 4-5 inches long, made directly over the tumour. After the separation of adhesions, and the mortality of the operation is in direct proportion to the extent of these adhesions, the stomach is clamped above and the duodenum below the growth, and the mass removed. The opening in the stomach is completely closed by a double row of sutures, and the duodenum united to a new incision on its posterior surface, as recommended by Kocher, and returned into the abdominal cavity.

2. The entire stomach has been successfully removed at least twice, and 7 months after operation Schlatter's patient was in good health with apparently normal digestion.

3. Gastro-enterostomy is the operation by which, after exposure of the pyloric tumour and adjacent stomach and duodenum, an incision is made into the free border of the latter beyond the pyloric obstruction, and the lips of the incision are stitched to the lips of a similar incision made in the coats of the stomach near to the pyloric end. Senn's plates and Murphy's buttons have been used for connecting the jejunum to the stomach, when they are not employed, the plan of simple suturing adopted by Barker gives better results than Wolfer's original method. The mortality is much lower than that of pylorectomy. No interference takes place with the tumour. The food passes directly from the stomach into the small intestine, though the pylorus is blocked up.

The operation has been many times successfully performed for

dilatation of the stomach caused by non-malignant strictures at the pylorus or in the duodenum.

Loreta's operation—the digital dilatation of the pyloric obstruction—is not warranted in malignant cases.

CANCER OF INTESTINES.—This generally causes death by obstructing the bowel, hence by dietetic treatment much can be done to prolong life by selecting foods which leave the least indigestible residue. Laxatives like Cascara, Sulphur, Olive Oil, or Cod Liver Oil, should be employed to keep the motions soft, and feeding by the bowel should be commenced early.

Enterectomy in certain cases affords great relief and prolongs life. The portion of bowel, the seat of cancer, is drawn out through an incision in the middle line below the umbilicus, and the diseased portion excised with scissors, the divided ends of the bowel brought into apposition and sutured with two distinct sets of sutures, one passing through the mucous coat alone (about 15 in number). The serous coats are next fastened by about 25 separate sutures, and the whole returned within the abdominal cavity, which is then closed in the usual way. Lembert's, or the Czerny-Lembert's sutures may be used, and the deaerified bone tubes (Paul's method), or Senn's rubber rings, or Murphy's buttons, are now constantly employed. It may be, however, found best to stitch the divided ends of the bowel to the skin wound, so as to produce an artificial anus, which, after a time, can be closed by a further resection, approximation and suturing of the divided ends, and their final replacement in the abdomen.

The operation of enterotomy may be done, by which an incision in the right inguinal region into the abdomen permits the surgeon to open the first distended coil of intestine which bulges into the wound. This method is applicable to grave cases where one is not justified in performing enterectomy. The distended coil protruding into the abdominal wound is sutured to the lips of the incision, after which the bowel is freely opened between the two lines of sutures, and an artificial anus maintained.

Cancer of the large intestine, leading to obstruction of the bowel, is best relieved by lumbar colotomy. Amussat's operation of opening the colon, either in the left or right loin, and permanently establishing an artificial anus, is the one most commonly indicated.

CANCER OF THE LIVER, hitherto regarded as beyond the reach of surgery, has been several times recently treated by excision. Locke, after opening the abdomen, excised a cancerous mass situated in the left lobe by drawing it through the abdominal wound, and fixing it there by sutures, the excision being performed by the slow pressure of the elastic ligature, aided by the cautery. Recovery was rapid the patient leaving hospital in four weeks. See other methods described under Liver, Cancer of.

CANCER OF RECTUM can only be treated satisfactorily by excision of the diseased portion of the gut, and most satisfactory results may be obtained even in cases where "obstruction

symptoms have been well marked provided the disease is within easy reach of the finger, and there is no infiltration into surrounding tissues, and the rectum is quite movable. The whole or a portion of the rectum may be removed. Though the operation is a very formidable one, a good recovery often ensues. Cripps emphasises the important statement that not more than 15 to 20 per cent. of cases which present themselves are suitable for operation. He insists that no operation should be undertaken unless there is a reasonable prospect of being able to make a thorough removal of the whole disease. Under ordinary circumstances the finger can explore to a distance of from four to five inches from the anus. If the finger can pass sufficiently beyond the disease to feel a healthy mucous membrane so far as the height is concerned a satisfactory removal is possible. It is, moreover, essential that the finger should determine that the rectum is movable and free, and that no infiltration into surrounding organs has occurred.

The writer had a case under observation where, after symptoms of obstruction had existed for several weeks, excision of a large portion—3 inches of strictured bowel—was most successfully performed by Mr Cripps nearly fourteen years ago; the patient had been seen by one of the most eminent living surgical authorities in London, who pronounced the case to be hopeless, beyond the reach of any operative interference, the malignant disease, in his opinion, having involved neighbouring organs. The patient is still living; most marked relief and great increase in body weight followed soon after the operation. There can be no doubt that the case was one of malignant disease, as the excised tumour demonstrated the fact.

The operation is a most formidable and tedious one, but the mortality in the hands of Cripps is under 8 per cent.

The introduction of the Kraske-Bardenheuer operation, the essential principle of which consists in the removal of the last piece of the sacrum and the coccyx, so as to expose the entire course of the rectum from behind, marks an enormous advance in rectal surgery. The whole rectum may be removed in this way, and the sigmoid brought down and sutured in favourable cases to the sphincter which is always preserved where possible. The pouch of Douglas may be opened without hesitation, and after this has been done it is surprising how easily and how far the upper segment can be drawn down.

Ball holds that it is rarely or never advisable to attempt to suture the upper segment to the sphincter, but I have recently seen a young man under the care of Prof. Sinclair who had six inches of the rectum removed, who one year after operation had perfect control over the sphincter, and could attend to his business with absolute comfort. When such a result is compared with the nameless horrors of an artificial anus comment is needless.—A. B. M.

F. Marsh advocates a preliminary colotomy or colectomy in all cases in which a proctectomy (excision of the rectum) is to be undertaken. Mitchell Banks, who prefers lumbar to inguinal colotomy, instead of merely opening the colon laterally, and stitching the lateral orifice to the wound, cuts the bowel clean across, and fixes the upper end. Thus he considers a necessary preliminary to proctectomy.

Where owing to extensive adhesions, infiltration of the bladder, or neighbouring viscera, complete removal is impossible an inguinal or lumbar colotomy will prevent the suffering attendant on attacks of obstruction. The former has the advantage of an external anus which can be easily cleaned by the patient, and especially of enabling the unfortunate sufferer to syringe out the diseased area with some suitable antiseptic wash which may diminish sepsis and control fetor.—A. B. M.

CANCER OF UTERUS.—The indications requiring treatment are pain, hæmorrhage, and fetor. The only satisfactory treatment is removal of the disease when this is possible.

The general health of the patient should be attended to, diet regulated, and moderate amount of stimulants in the later stages. The patient, if confined to bed, should be placed in an upper room, with a sunny aspect and good ventilation. The air of the apartment should be kept sweet with Terebene, or any fragrant essential product. Sawdust sprinkled with Oil of Turpentine is a good disinfectant and is not suggestive. The bowels should be kept normal with a laxative like Cascara or Sulphur, or by enemata of tepid water.

Pain will be best relieved by Morphia or Opium in the form of suppositories. It is a mistake to begin with hypodermic injections. 1 gr. by bowel or 1 gr. Opium by the mouth will generally be sufficient to lull pain at first, but at a later stage often large doses are required hypodermically. Medicated pessaries are not so satisfactory as suppositories.

Pain is best met by thorough cleanliness and good nursing. Antiseptic injections—Borax in saturated solution, Carbolic Acid (1 to 3 parts), Bromine (1 in 500), Acetate of Lead (1 oz. to 1 gallon), Permanganate of Potash (5 grs. to 20 oz.), Bichloride of Mercury (2 grs. to 1 pint), Creolin (1 in 20) may be employed.

Cheese recommends the following deodorising injection, 1 oz. of which may be mixed with a pint of water, and injected every four hours—

Salicylic Acid, 8 grs.; Salicylate of Soda, 3 drs.; Tincture of Eucalyptus, 6 drs.; Water, 6 oz.

The effect of these injections is but temporary, and their deodorising or deodorising qualities last but a very short time—a matter of minutes—and it is necessary to leave some more concentrated preparation in the vagina to prevent the patient becoming a burden to herself and her friends.

Iodoform is the most powerful of all remedies. Pledgets of

cotton wool or lint, soaked in a mixture of Iodoform, rubbed up with Glycerin, destroy all trace of odour. 1 to 40, or in bad cases 1 to 8, may be employed, and left in the vagina all night.

Playfair uses in a similar way a mixture of 1 oz. Glycerin of Carbolic Acid and 8 oz. Glycerin of Tannic Acid.

Betrin uses tampons soaked in equal parts of Terebene and Almond or Olive Oil after an abundant preliminary douche of Condy's Fluid and Water.

Oil of Turpentine, shaken up with water, 1 in 100, may be used as an injection, or mixed with Olive Oil, 1 in 4; it may be applied on tampons.

Packing the vagina with powdered Boracic Acid is a good plan. The plugs should be removed twice a day, and the vagina well syringed with any of the above lotions each time.

Hæmorrhage is best checked by local applications or plugging of the vagina; hæmostatic remedies by the stomach are not to be depended upon. Should the bleeding be alarming, plugging must be resorted to, and if from the body of the uterus, the os being dilated, strong Perchloride of Iron Solution (1 to 4) may be injected. Cold saturated Solution of Alum answers well in most cases. If the source of the hæmorrhage be within reach and visible, the bleeding point may be touched with any strong caustic, as concentrated Liq. Ferri Perchlor., or a minute pledget of lint soaked in it may be left in contact, and the vagina plugged with wool soaked in weak Carbolic Oil (1 in 20). The writer, however, never uses Carbolic Acid where there is a distinct fetor; the combination of the odour of the acid with the fetor makes generally a new volatile compound of still more disgusting smell. Chloride of Zinc freely applied to the bleeding spot is reliable; it also checks the disease by destroying the growth.

The galvano- or thermo-cautery may be employed; if the hæmorrhage recurs the bleeding surface may be thoroughly scraped with the curette. The Puff-ball may be pushed through the speculum and left *in situ* as a plug in severe cases. Ice may be also useful sometimes, and it has the advantage of being easily used by the patient. A powerful continuous current (Apostoli's method) is effective.

The local application of Suprarenal Extract is most efficacious.

The surgical treatment of uterine cancer will depend upon the portion of the uterus invaded. The epithelial growths springing from the os and cervix may be removed, in some instances completely, without interfering with the body of the uterus. Caustics—Caustic Potash, Zinc Chloride, Arsenic, Alcoholic Solution of Bromine (1 to 5), strong Nitric and Carbolic Acids—are used but seldom do good results follow. Often the inflammatory action following their irritant effect gives a fillip to the disease. The three first on the list just mentioned may eat their way through diseased tissue, but unless applied with great skill and care their action cannot then be stopped, and the danger is thus

so great that their use is to be condemned as a routine method. The remaining members on the list are too superficial in their action to be of any permanent benefit.

If Chloride of Zinc be used by Braithwaite's method, excellent results may be obtained in selected cases. He takes the fluid resulting from the deliquescence of the solid Zinc Chloride, thin layers of cotton wool are wetted in this saturated solution, and the superfluous moisture is removed by lightly pressing them between sheets of blotting paper. These are applied for 24 hours, the healthy parts being protected by tampons soaked in Soda solution. By care and the re-application of the caustic the disease may be destroyed to any depth. The healing process afterwards is followed by great contraction and puckering of the parts.

Scraping away of the diseased surface by means of Simon's sharp spoon or by the ordinary curette, is a much better partial operation than the destruction of the tissue by caustics. After all the diseased growth is thus removed down into the sound tissue by firm scraping the cautery is applied, and a still further layer destroyed or caustics may be used with much advantage.

Curetting may be combined to great advantage with Chloride of Zinc. After all the diseased tissue has been thoroughly removed by the spoon, cotton wool damped in saturated solution of the caustic may be applied to the raw surface to destroy rays of cancerous growth which escape. Many operators prefer this method to the cautery or knife. The writer has several times employed it, and watched its effect in the hands of others, and believes that it is the best of the *partial* methods of dealing with uterine cancer. Nearly the entire uterus may be removed in this manner, only a thin layer of healthy uterine tissue being left.

Amputation of the cervix by the knife or scissors, and stitching together of the mucous membrane over the wound or the insertion of deep sutures into the incised lips of the cervix after the removal of a wedge-shaped mass of malignant tissue, is also followed by good results in a fair proportion of cases at the early stage. The entire cervix may be amputated. Marion Sims applied strong caustics after these partial operations. Chloride of Zinc (1 to 1 or 1 to 2 of water) is applied upon plugs of lint three or four days after the amputation, and left *in situ* for one or more days, the vagina being protected by tampons of cotton wool soaked in saturated solution of Soda Bicarb.

The general tendency of modern surgery is in the direction of thorough and extensive operations for the removal of cancerous growths, and most operators now prefer complete hysterectomy for all cases of uterine cancer whether originating in the fundus or cervix. The route generally selected is through the vagina, and under modern methods the mortality of vaginal hysterectomy is very trifling, some operators having recorded as many as 40 to 50 cases without a death.—A. B. M.

More Madden has entered a strong protest against this growing practice, and after long experience expresses a very decided opinion in favour of amputation of the cervix alone, where the disease is limited to the region of the external os.

Dudley, on the one hand, states that "the radical treatment should always be complete hysterectomy. The old practice of high amputation of the cervix for cervical cancer should never be resorted to."

Upon the other hand, Byrne states that he has operated upon 367 cases of uterine cancer with the galvano-cautery, and the average period of exemption in known cases was eight years and seven months. He amputates the cervix with the loop, and cauterises the mucous membrane of the uterus and the stump by an instrument passed into the cavity.

The results of removal of the uterus for cancer are much more satisfactory than might be expected. Leopold reports that out of 76 of his cases remaining under observation after recovery 72 were still well without recurrence of the disease from 1 to 5½ years after the operation. The Dresden Klinik figures show that of 72 cases examined after 5 years, almost 60 per cent, showed no return.

CANCERUM ORIS.

Constitutional treatment is of great importance in this formidable affection. Nutritious diet, with stimulants, free ventilation, and everything that can improve the general condition of the ill-fed and badly cared-for child, must be insisted upon, but no time is to be lost in resorting to the only local treatment available, i.e., the free application of powerful caustics to the sloughing spot. Strong Nitric Acid is by far the best remedy, and it should be applied, under Chloroform, after the inside of the cheek is exposed and wiped dry, care being taken to prevent the acid finding its way to the healthy surrounding mucous membrane. Poultices may be applied externally; but if a gangrenous patch is visible externally, it should be cut or scraped out, and the strong acid applied freely to the margins of the hole.

Stephen Paget recommends that desperate cases should be promptly treated by excision of the slough and surrounding ring of healthy tissue by the knife. Trounseau applied the actual cautery.

In mild cases weak Corrosive Sublimate Solutions may be used, and even in severe cases speedy recovery has followed their use. Gates and Kingsford report success in three cases, by cutting away all sloughing masses and swabbing the ulcerated surfaces once or more daily with a 1 in 500 Perchloride of Mercury Solution, whilst a 1 in 1,000 solution was kept constantly applied. Healthy granulations soon appeared, and recovery was rapid.

Kostuern has reported the success of a watery solution of *Methylene Blue* (1 in 4) after failure of the actual cautery and

many other caustics. He applied the solution every hour with a brush.

Ammonia and Cinchona, with stimulants, must be pushed, and if concentrated Beef Essences and Soups cannot be swallowed, they should be given by the bowels or by the nasal tube. The local after-treatment will consist of free applications of Chlorate of Potassium, dusted in fine powder over the sore, or the mouth and cheek may be syringed with a solution of the drug (1 to 50) several times daily. The most rigid cleanliness is essential, and the syringe should be used almost constantly at first. Iron must be given internally, and the most liberal feeding kept up for a long period. The resulting deformity may be remedied afterwards to some extent by operation.

CARBOLIC ACID POISONING—See under Poisoning.

CARBUNCLE.

In the management of this affection a generous diet, with stimulants and, if possible, open-air walks or drives are essential. Iron, internally, in doses of 15 minims of the tincture with 2-3 grs. Quinine four times daily, should be given from the beginning, with saline purges every second morning. Sulphide of Calcium in $\frac{1}{2}$ gr. doses every two hours has been used to influence the suppurative process, and Arsenic is useful in chronic cases. If great prostration be present, a mixture of 2 oz. Spt. Ammon. Aromat. and 2 oz. Tinct. Cinchona may be given in doses of a large teaspoonful with a table-spoonful of Brandy in a wine-glassful of water every two hours. Opium or Antipyrine may be given to relieve pain and to assist sleep.

LOCAL TREATMENT—Some surgeons believe that when a carbuncle is seen early it may be destroyed by the application of a pointed stick of Potassa Cum Calce but in the great majority of cases the best local treatment should consist of a free crucial incision across the face of the carbuncle, through skin and slough down to the healthy tissues beneath. A hot poultice, rendered antiseptic by a coating of Boracic or Iodoform Ointment, should be applied, but constant poulticing is to be avoided after the early stages.

All the benefits of a poultice during the healing stage may be obtained by any antiseptic lotion on lint, covered with oiled silk, and upon the top of which a pad of cotton wool is fixed with a bandage or strapping.

Carbolic Acid is injected into the slough by some surgeons without making the crucial incision. Recently this treatment has been modified by diluting the Acid and injecting small quantities (about 1 drachm in all) into different parts of the tumour. The following is the usual formula, and excellent results are reported.—Pure Carbolic Acid, 1 part, Glycerin and Water, of each 5 parts.

The writer, after making the two deep incisions at right angles to each other, thrusts deeply into the slough at two or more points a piece of lint wrapped around a stout director and dipped in the strongest Carbolic Acid.

It is a good practice in some cases to push in small fragments of Caustic Potash through the openings in the carbuncle.

Satisfactory results have been obtained by playing the spray of a Carbolic Acid Lotion (1 in 50) upon the carbuncle for about 15 to 20 minutes every 4 hours, and avoiding incisions. This treatment can be combined with incising or using caustics or poultices.

Strapping, by firmly getting a good hold upon the healthy tissues on each side, hastens the discharge of the slough and gives great relief. A fair opening being left in the centre of the plaster for the drainage of all discharge.

The old expectant treatment, by poulticing and hot fomentations, is tedious, and favours blood-poisoning, and the method of applying weak Iodine under compresses is also of little use in most cases. Pain may be relieved by applications of Extract of Belladonna rubbed up with Glycerin, and smeared over the part, or applied upon the surface of the poultice. Cocaine Solution, 2 per cent, may be applied under oiled silk, and Chloral Solution (5 grs. to 1 oz. is a good lotion at a later stage. Wirtz speaks highly of the application of Thiol over the infiltrated parts, and has found it to give complete relief from pain.

Blistering, Arica, Collodion, and Mercurial Ointment, have been advocated; but the free incisions, followed by poulticing and antiseptics, afford best results.

Ether, sprayed upon the slough, is said to hasten its removal.

Teale and Page have reported cases where "Scraping" was performed by a Volkmann's spoon or Lister's scraper with great success. —After a crucial incision, the slough is entirely scraped out, the indurated edges cut away by scissors, and an open ulcer left which heals rapidly under any simple dressing, Iodoform or Cyanide Gauze being perhaps the best. I have several times followed this practice, and always with most satisfactory results. —A. B. M.

Rushton Parker excises the carbuncle completely cutting wide of all suspicious tissue. The extensive wound is dressed with cyanide gauze, and heals rapidly.

Should there be much fetor, Sublimate Solution (1 in 5,000) or Turpentine, or Terebene, or syringing with Solution of Chlorinated Soda (1 dr. to 1 oz., or Condy's Fluid and water may be employed. Iodine Linctus, very freely painted round the base, gives relief, and subdues pain caused by congestion in the surrounding healthy tissues after the carbuncle has been incised.

The severe form of carbuncle attacking the face, must be treated upon the same general lines—supporting diet and stimulant incisions and antiseptic poultices.

CARIES.

Bone caries being, in the great majority of cases, a local manifestation of struma or tubercle, constitutional treatment is of the greatest importance and there can be no more serious mistake made by the surgeon than to confine his efforts to the local management of the case. The best treatment is that indicated in strumous affections—Cod Liver Oil and Malt Extract; taken in large quantities; the removal of the patient to a sea-side where sheltered from east winds and protected from the north; iodides, chiefly Ferri Iod., Phosphates, Hypophosphites, Calcium chloride, Gold and Barium Salts, and other remedies mentioned under Scrofula and Tuberculosis.

Local treatment will vary with the anatomical position of the bone affected. In all cases rest must be insisted upon, and this should, if possible, be supplemented by the application of a splint, or immovable apparatus, which will enable the patient to spend the greater portion of his time in the open air. It is a serious matter when patients, the subject of bone caries, are sent abroad especially in crowded cities.

The cases naturally divide themselves into three groups:—

1. Where there is no evidence of abscess formation.
2. Where an abscess has formed.
3. Where the abscess has burst, leaving one or more sinuses leading down to the diseased bone.

In the first class reasonable trial should be given to hygienic treatment, absolute fixation of the affected region, with local application of Oleate of Mercury Ointment and Vaseline equal parts, counter-irritation pressure, etc. Under such methods many cases will undergo complete cure. I have more than once seen well-marked dactylitis, in which subperiosteal resection had been strongly urged, make a perfect recovery under more cautious treatment. In such cases the entire hand and wrist, and not the affected finger only, should be fixed in a splint which may be moulded of poroplastic felt and be both light and comfortable. Should, however, pain and tenderness continue and swelling increase in spite of such treatment, then more active interference is demanded, and this is especially so if the disease is in the neighbourhood of an important joint.

The affected area should be carefully sterilised, a skin flap raised, and all softened bone, and a zone of healthy bone around, excised by gouging and curetting with Barker's flushing curette. The cavity should then be thoroughly dried, treated with boiled cod liver Emulsion, and the wound sutured without drainage. If the operation has been aseptic, primary union will result. The bony cavity will become filled with clot, which will organise into bone.

In the small bones of the carpus and tarsus complete resection gives the most satisfactory results.

2. Where an abscess has already formed, palliative treatment

The abscess should never be allowed to burst, nor should it be treated by simple incision and drainage.

Where possible the surgeon should aim at complete removal of the abscess sac, by dissecting it out if feasible, or by thorough scraping. The affected bone is then removed, and the wound closed without drainage. (See Abscess, Chronic.) I have many times had a perfectly satisfactory result in this way, but rest should be insisted on for 2-3 months after operation to ensure thorough organisation of the clot, etc.—A. B. M.

3. Where sinuses have already formed they are invariably septic. Should operation be undertaken, the sinuses must be involved in the incision and their unhealthy edges removed. If softened bone scraped away, the cavity swabbed with pure Carbolic Acid, lightly packed with Iodoform, or Cyanide Zinc, and allowed to granulate from the bottom. The course of such cases is slow, and the result often disappointing.

Various methods of treating the disease, by injecting substances into the sinuses, have been advocated. The writer has seen excellent results from the injection of the undiluted Compound Tincture of Benzoin, as practised by the late Professor Goode. Pollock advises the injection of strong Sulphuric Acid and water in equal quantities, the strength of the acid to be gradually increased till it is injected pure.

Red Precipitate upon a moistened probe was an old method of setting up new action in the sinus and bone.

Turpentine, Caustic Potash (liquefied), Tincture of Iodine, Villate's Solution (Zinc and Copper Sulphates, Liq. Plumbi, and Vinegar), and many other compounds have been used for the same purpose with varying success.

If the carious bone is easily reached, strong caustics, as Caustic Potash, Chloride of Zinc, or the Actual Caustery may be freely applied to the carious cavity after a free incision through the skin. The bone may be entirely excised, which is the best treatment for the small bones or os calers, when extensively diseased.

See under Tuberculosis for an account of Koch's method, and for the still more recent plan of Lannelongue by injecting Chloride of Zinc into the surrounding tissues. (See also under Necrosis.)

~~Resection~~ of an entire bone, Excision of carious articular ends, or even Amputation, may be demanded in some cases but the surgeon should always recall the extremely unpromising cases where such measures were recommended as absolutely necessary, but rejected by the patient, who afterwards became perfectly restored to health by ordinary hygienic measures.

CARIES OF SPINE.

This affection can only be treated by thorough constitutional measures, supplemented by *prolonged* rest, and *prolonged* fixation of the spine. Cod Liver Oil with Malt Extract, Iodide of Iron,

Hypophosphites, and the various remedies applicable to wasting diseases and tubercle or struma (which see); liberal diet of Fermented Milk with Koumiss (page 26), and Beef Juices or Meat diets. Open air when possible, and change to a sheltered seaside spot, with cheerful surroundings, should be advised.

In the early stages of the disease, where the diagnosis is based upon neuralgic pains or numbness in the legs and other symptoms before there is any local deformity, absolute rest in bed or upon a hard mattress in the open air is essential. This treatment must be insisted upon for months. There can, however, be no greater mistake than to rely on rest in bed alone. Once the diagnosis of Pott's Disease has been made, be the case mild or severe, the sooner a properly-fitting spinal support is applied the better. Nothing gives such prompt and permanent relief to pain and tenderness as a suitable apparatus accurately adapted to the spine, and this should be worn day and night without intermission. It is commonly taught that the chief advantage of a spinal support is that it enables the patient to get into the open air; this is not so. The object is to fix the spine whether in bed or out, and to prevent that forward bending which causes pressure on the bony bodies and produces the well-known angular curvature.

The simplest and most efficient appliance is Noble Smith's "Adaptable Metal Splint," which can be made by any instrument maker at a cost of about two guineas. It is fully described in his work on Spinal Caries.

For young children a Thomas double hip splint is very satisfactory. Nursing is by this means greatly simplified, and the sufferer can be moved and carried into the open air without pain. Where a special splint cannot be obtained, a Plaster Jacket is the best substitute.

To apply the jacket, the patient should be stripped of all clothing, and a neatly-fitting woven merino vest, without buttons, should be put on. It should reach below the buttocks. He is then suspended by the usual pulley and cord appliance, by means of a strap passing below the chin and occiput, and another under each armpit. It is not necessary to raise him entirely off the ground; his toes should be left touching, as it gives confidence to him, and if absolutely complete extension be needed, by flexing his knees very slightly the toes will, of course, leave the ground.

The vest is pulled gently downwards, and all wrinkles removed, and a pad placed inside it over the pit of the stomach. This is to be slipped out afterwards, its object being to leave room for distension of the abdomen after meals. Coarse muslin (ermoline muslin bandages, thickly sprinkled over with the finest quality of Plaster of Paris, are to be rapidly immersed in hot water, tightly squeezed out and applied over the vest in layers, extending from about an inch below the thiac spines to the armpits. An assistant smooths down each layer of bandage as it encircles the trunk, and from time to time, applies with his hands some

more plaster, made into a cream with water ; or, if the bandage appears to have been too well moistened, he rubs over it a little dry plaster as the operation proceeds.

For small children, 3 inch bandages 3 yards long will answer 4 or 6 of these may be used. Adults require longer and broader bandages, and a larger number of them.

Should the patient be thin, small pads of wadding may be placed over any bony prominences outside the vest before the application of the first bandage, which may be passed round the pelvis, and brought obliquely upwards as it encircles the abdomen, fixing permanently in their position all woollen pads over the most spines or prominent vertebrae. After the application of the last bandage, the assistant applies some fresh plaster, rubs it down with his hand, and finishes the jacket off, leaving a smooth and even surface. It sets in a few moments, and the patient may be taken down and laid flat upon a hard mattress before the fire for a short time before being carried to bed, from which he may get up next morning and run about. By turning up the tails of the men's vest over the plaster, near the end of the operation, a more presentable finish off is obtained. The jacket may be worn for two months or more, and may be cut up, punched with holes, and laced on again if found quite satisfactory. In this latter case it can be taken off at night. Several jackets may be applied during the course of the disease.

In the case of very young children, the plaster bandage, having been cut into suitable lengths, may be arranged upon the plan of the old many-tailed bandage and slipped under the patient's trunk as he lies quite flat, and in this way on the application of more plaster or moisture, a good jacket can be fitted without any extension upon the tripod. The writer has been able to apply the ordinary plaster bandage to a young child, with the aid of an assistant supporting him, without the tripod.

When consolidation has advanced to a considerable degree, the Plaster of Paris Jacket may be replaced by one made of Poroplastic Felt. Jackets ready-made, of various sizes and shapes, may be obtained from any instrument maker, and rapidly adjusted to the patient's body when suspended. The Felt Jacket is put into an ordinary range oven, and, in a few minutes, it becomes quite soft and pliable, in which condition it is moulded to the chest and abdomen, fastened with buckles, and the setting process is complete in 5 to 10 minutes, during which time the suspension is to be kept up. It can, every 4 or 6 weeks, be reheated and applied again, as it yields a little with the heat of the patient's body. Some cases of spinal caries, in weak and thin subjects, can be treated in this way from the first. It has the great advantage of being easily taken off and put on, and allows of daily inspection if abscesses are feared. The Wood, Celluloid, and Aluminum Corsets are most suitable in the convalescent stages.

In disease of the highest cervical vertebrae, the patient must be

laid upon his back with the neck fixed in a comfortable position with pillows and sandbags, as long as any acute symptoms are present. Afterwards a modification of the Plaster Jacket may be applied, carrying narrow plaster bandages round the forehead, over the ears and occiput, and under the armpits.

In disease of the lower cervical segments, Savre's jury-mast apparatus should be applied. It may be adjusted in connection with a Poroplastic instead of a Plaster of Paris Jacket, or a support to the head may be added to the splint already mentioned.

Hadra has suggested the heroic procedure of wiring of the vertebrae after other measures, such as trephining of the vertebral arteries, &c., had failed.

Laanelongue's new method of treating osteo-arthritis and caries, by deep injections of the Chloride of Zinc, will be also found detailed under Tuberculosis.

In paralysis of the legs caused by spinal caries, where the above means have failed, extension may be tried by means of weights, applied whilst the patient is lying in the horizontal position on his back; or Horsley's rubber accumulators may be slid on to the bed and attached to the patient's limbs. Permanent results have been obtained by cutting down and removing the spines and laminae of several vertebrae, and dissecting away any fibrous tissue, inflammatory, or caseous products from the surface of the dura matter. Many cases are recorded where immediate relief to the paralysis has followed laminectomy, and the results have been permanent. A still better operation is to remove the transverse processes, and spinal ends of one or two ribs (if in the dorsal region), and scrape away the diseased bodies, necessary establishing drainage. Mr. Kirk has had some very permanent results after this procedure.

Most cases of paraplegia dependent on caries will, however, recover under rest and spinal fixation, and operation should be a last resort. Noble Smith, with his long experience, states that he has never had a case which did not recover.

Forcible straightening of angular curvature under chloroform has been strongly advocated by a few surgeons during the last few years, but the profession has not given much support to this heroic procedure, and it is not likely to be extensively followed.

The results of treatment in spinal caries are very encouraging, and Noble Smith goes so far as to say that "every case of caries of the vertebrae in which the health of the patient is not absolutely undermined is not only curable, but curable without any increase in the deformity."

CATALEPSY.

The treatment of this condition means generally the treatment of hysteria, of which it may, however, be the only symptom. If there be loss of consciousness associated with the muscular rigidity, the patient should be aroused by a good dash of cold

water thrown suddenly over the head and face. Should this fail a smart electric shock from a frictional machine, or what is much more convenient, a pretty severe induced current may be passed through the arms. It should be suddenly applied in full strength, and not turned on gradually. One pole may be applied to the upper part of the spine, and the other to the rigid limb. Gowers states that a pinch of snuff may soon restore consciousness, or Hare's plan of closing the mouth and nostrils for about 30 seconds, or the method of pouring a little water down the throat or nostrils so that some may get into the larynx and provoke coughing. Emetics often dispel all symptoms, but the patient is either unwilling or unable to swallow them, and it is best to administer $\frac{1}{16}$ gr Apomorphine hypodermically. After the attack passes off drachm doses of the Annotated Tincture of Valerian, with a little Asafetida, have a good moral influence. Should there be a very distinct series of attacks, the removal of the patient from her surroundings and a good course of massage and forced feeding will prevent a return. In the presence of delusions or other forms of insanity the administration of severe electric shocks or cold douches must be avoided.

Cannabis Indica in small doses (2-5 minims of the tincture) is credited with special virtues.

CATARACT.

The only satisfactory treatment is operation. In the early stages of nuclear cataract, smoked or dark glasses give some relief by favouring dilatation of the pupil, and, in some cases, the sight may be much improved by keeping up moderate dilatation by using an ointment consisting of $\frac{1}{4}$ gr. Atropine and 4 drs. Vaseline.

Operations are of various kinds:—(1) The removal of the lens-entire through a large corneal or sclero-corneal wound, leaving the capsule behind. (2) The removal of the lens in a similar way along with its capsule. (3) By causing absorption or solution of soft cataracts by admitting the aqueous humour through needle punctures made in the capsule. (4) By removal of soft cataracts through a small linear corneal section. (5) By couching or dislocating the lens backwards into the vitreous. This operation is not practised now. (6) By McKeown's method, whereby urripe cataracts are operated upon, irrigation being used to clear out the residue of the lens.

Needle operations, generally speaking, are not applicable after 25 or 30 years of age. The use of Cocaine renders most cataract operations possible without Chloroform or Ether—a vital point, considering the dangers attending the act of vomiting or retching.

Some lamellar cataracts, with a wide, clear, marginal zone, may be best treated by doing an iridectomy, which will uncover a transparent portion of the lens, and give fairly good vision.

In young subjects, the best operation is the needle one, and some opaque lenses may be completely removed by a few insertions of

the needle through the cornea and laceration of the anterior capsule and fibres of the lens, and exposure of them to the absorptive action of the aqueous humour, the posterior capsule being left behind to shut out the vitreous. The iris must not be touched with or touched by the needle, and Atropine must be then used before and for a time after the operation, or until the next insertion.

The operation of linear extraction is applicable to soft cataracts where the needle fails, and to other cataracts where lime is an important element, and to some cataracts where needling has already been tried. A short incision is made with a triangular keratome a little within the margin of the cornea; iridectomy is unnecessary. The capsule is opened by the cystotome or by the point of the keratome. By slight pressure on the globe the soft vitreous substance is evacuated piecemeal, any portions remaining being soon absorbed, as in the needle operation. If instead of pressing out the softened lens a fine syringe be inserted, the latter may be sucked out through it. This is known as the Syringe Operation, and, of course, is only applicable to very soft cataracts, but it is not a very safe proceeding, and is seldom resorted to now.

In the treatment of hard cataracts an operation should be seldom undertaken if there be evidence of deep-seated disease. If there be total absence of all perception of light, though the cataract be very dense, no operation should be recommended, and under no circumstances should both eyes be operated upon at the same time.

There are many modifications and varieties of operation for the extraction of hard cataracts. Graefe's modified linear operation is performed, (1) by making an incision slightly beyond the sclero-corneal junction by a long narrow knife; (2) a small part of the cornea beneath the incision is excised; (3) the anterior capsule of the lens is freely lacerated; (4) by gentle pressure the hardened lens is squeezed out of its capsule and through the incision; (5) the "wicket" of the wound is to be carefully seen to. Irrigation, by means of McKeown's syringe and needles, is far preferable to pressure, either digital or instrumental.

The old flap operation, performed by making an incision within the visible margin of the cornea for about half its circumference, and concentric with it, by entering a Beer's triangular knife at the margin of the cornea and cutting out a semi-circular flap without making an iridectomy, is seldom performed now. The capsule was opened by the cystotome, and the lens easily escaped through the opening, spontaneously or upon very gentle pressure. Wicker's flap operation is now most in favour.

After operation the patient is put to bed in a darkened room, and a piece of linen, covered by a pad of absorbent wool, placed over each eye and bandaged by a four-tailed knitted cotton bandage. This need not be disturbed for two to four days if all

goes well), when a few drops of Atropine Solution may be instilled and the bandage re-applied.

After the fourth day he may be allowed to sit up, and the bandage may be removed at the end of ten days and a shade substituted.

Extraction without iridectomy—so-called "simple extraction"—is now practised by many surgeons, and is probably done in the majority of cases in America and on the Continent, though not yet so frequently in England. The advantages are less risk of inflammation (since the iris is not wounded) and a round contractile pupil is the result. A good plan is to remove the lens without iridectomy after very free laceration of the capsule, replace the iris if it is in the corneal wound, bandage up the eye and examine it in 24 hours. If the iris then shows signs of prolapsing the wound is opened with a spatula and an iridectomy done. Some few surgeons use transparent adhesive plaster to close the lids instead of a bandage, but its risks are greater than its advantages.

McKeown's method of using irrigation marks a very distinct progress in ophthalmic surgery. In a considerable number of ordinary cataract operations, where the cataract is regarded as ripe before operating the surgeon finds that the cortex remains and gives much trouble. Here massage pressure, and the use of the scoop are the usual means by which the residual cortex or debris is to be cleared away. When they fail, irrigation usually succeeds.

It is, however, in dealing with unripe cataracts in those where before operation is attempted, the surgeon knows that he is dealing with a transparent and sticky cortex, that the plan of irrigation is most valuable. The term irrigation is an unfortunate one; it would be better to speak of it as "the method of removing the cortex by fluid pressure." By it the cataract patients, who were formerly doomed to wait for months or years till their sorrow became ripe, can, in the majority of cases, be operated upon with every prospect of success without delay. This is a great gain in the case of the poor, and artisans or labourers.

The operation is done according to the ordinary methods with or without iridectomy and after the extraction of the lens the fine nozzle of an irrigation apparatus a suspended bottle with a bent syphon tube in its interior filled with about 4 ounces of warm distilled water previously boiled is introduced through the wound. The strictest antiseptic precautions are used. As the stream of sterilised water is introduced inside the capsule, "there is no pressure on the cornea, no pushing back of the vitreous, no squeezing towards the wound of the hyaloid membrane. The current of water under the control of the surgeon flows inside the capsule to the periphery, and returns along the anterior and posterior capsule searching every corner, and bringing with it fragments of cortex from every part of the capsule. The force is

equable and gentle, and acts not only on the parts we see, but on those concealed by the iris, and quite as well upon the parts concealed as on the parts visible." The complete extraction of the cataract, therefore, becomes simply a question of physics, of relative resistance, and relative well-directed and suitable force.

The former objection to McKeown's method—that it does not adequately provide for asepsis—is now entirely removed by Cecil Shaw's modification of the apparatus, which is now adopted by McKeown. The flask is half filled with a 2 per cent Sodium Chloride solution, and all air, entering after boiling, is filtered through a thistle-headed funnel filled with absorbent cotton-wool.

CATARRH—See Bronchitis.

In the treatment of nasal catarrh or coryza, much relief may be obtained by local remedies, the best known of which is Ferriér's Snuff, which may be insufflated every few hours. Two grains of Cocaine may be added with advantage.

- R. *Bismuthi Subnit.* \mathfrak{v} i.
Pulv. Gum. Acacia \mathfrak{z} ii.
Morphina Hydrochlor. gr. ii. *misce.*

A good formula is Cocaine Hydrochlor., 1 gr.; Menthol, 2 grs.; Salicylic Acid, 5 grs.; Boric Acid, 1 dr.; Powdered Marshmallow, 2 drs. Another is—Cocaine, 1 gr.; Salol, 45 grs.; Salicylic Acid, 25 grs.; Tannin, 12 grs.; Boric Acid, 1 oz.

A mixture of Iodoform and Tannin may be employed in the same way. Plugs of cotton wool saturated with Cocaine (4 per cent, or Menthol .8 per cent.), may be inserted into the nostrils. Petroleum containing $\frac{1}{2}$ per cent Menthol and 1 per cent. Camphor may be used as a fine spray with great advantage. Solution of Nitrate of Silver, 10 grs. to 1 oz., may be freely applied with a brush, or Zinc Sulphate, 5 grs. to 1 oz., may be used. Sprays of weak Carbolic Solution (1 in 20), Ipecac Wine or Sulphurous Acid, inhalations of Ammonia, Ammonium Chloride, Carbolic Acid, Benzoin (Tr. Benzoin. Co.), Camphor, weak Iodine solutions (1 dr. tincture to 1 oz. water), Eucalyptus, and many other remedies mentioned under Bronchitis, may be used. In the chronic form of nasal catarrh, the Chloride of Ammonium Inhaler is the best.

Benzoate of Soda in drachm doses may be given at the beginning of an attack, and one full dose of Morphia is believed by some to cut short the coryza before the irritation extends downwards. Belladonna or Atropine (1 minim B.P. Solution), often affords relief if given every six hours. (See also under Hay Fever.)

For post-nasal catarrh the first step should be to remove the cause, as polypus, turbinate enlargement, pharyngeal tonsils,

adenoids, general rhinitis, or empyema of the antrum. In the simple catarrhal form, where no objective disease can be detected cautious cauterization of the mucous membrane on the posterior wall stops the profuse discharge. Where this is not profuse but tenacious MacDonald advises a nose wash of Chloride of Ammonium (5 grs. to 1 oz.). He condemns the use of the nasal douche and post-nasal syringe.

CATHETER FEVER—See Urethral Fever.

CEREBRO-SPINAL FEVER — See Meningitis, Cerebro-Spinal.

CHANCER—See under Syphilis.

The treatment of Soft Chancre is for the most part simple. Absolute cleanliness is indispensable at all stages; and after the ulcer is thoroughly cleansed and dried, powdered Iodoform should be sprinkled over it and kept in contact by a piece of dry lint or iodoform gauze. In the great majority of cases, morning and evening applications of this remedy effect a speedy and satisfactory cure, and nothing else is required. The writer, however, makes it a routine practice to destroy the surface of the sore with a caustic, as it is very often difficult to be certain that the chancre may not turn out to be a true Hunterian one, the result of a connection prior to that suspected by the patient, in any case this is the best treatment as it converts the sore into a simple granulating wound. When the caustic is applied with care no harm ever results, and healing in all cases is hastened, for this purpose the writer, after cleansing the sore with dry lint, lightly applies a little Liquor Hydrarg. Pernit., pure Carbolic or Nitric Acid. This treatment is imperative in all cases where the chancre shows any signs of spreading. The pure Carbolic Acid applied on a little wool twisted round a piece of match wood meets nearly every requirement in the great majority of cases.

The great draw-back to Iodoform is its tell-tale odour, as a rule, far more is applied than is necessary, and with neatness in dusting, when the patient has a long prepuce, its odour need not be diffused but when the sore is outside the prepuce the drug may be mixed with Tonquin bean or coumarine (1 gr. to 1 dr.) to disguise the odour. Aristol, Dermatol, Iodol, or Di-Iodoform may be used. Canazzani treats all soft sores by applying a mixture of 5 drs. Chloral Hydrate, 3 drs. Camphor, and 3 oz. Glycerin. Where there is much swelling or pain about the prepuce cooling lotions may be used. The Stockholm treatment, as carried out by Wielander, consists in keeping the sores covered by lint maintained at a temperature of 41° C. to destroy the virulence of the secretion.

A very good plan is to sprinkle the soft chancre over with Antifebrin twice a day. The substitutes for iodoform are practically numberless.

Worster's plan is to spray (under a pressure of 60 lbs.) the chancres with pure Hydrogen Peroxide, when they soon begin to heal rapidly.

Circumcision is often necessary where the prepuce is tight, and this must not be delayed if any signs of sloughing should appear, caustics being applied freely after the operation. For the phagedenic sore the best remedy is strong Nitric Acid. (See also under Bubo.)

CHAPPED HANDS.

The skin should be protected as much as possible from atmospheric changes, and when washed or wetted should be carefully rubbed dry with warm towels. The practice of partially drying with damp cloths, and then heating before a fire, has much to answer for in causing the affection. A superfatted soap is the best, and of all the numerous applications there is none to equal the following ointment, which frequently works wonders in one night:—

R. *Liquor. Carb. Deterg. Ziss.*
 Hydrarg. Ammon. Chlor. gr. xiv.
 Lanolin. ℥i. misce.

Fiat Unguentum.

This applied freely at night with gentle friction, and covered with chamois gloves, very often removes the condition after a few days. Other good applications are—Glycerin, Glycerin and Rose Water (1 to 5), Glycerin and Friar's Balsam (4 to 1), Glycerin and Eau de Cologne (2 to 1), Glycerin of Starch, Glycerin and diluted Lead Solution (1 to 8), Glycerin and Hydrastis (Glycerin, 3; Hydrastis Tincture, 1; Rose Water, 10), Vaseline, Cold Cream, and Vinosa Cream.

CHEYNE-STOKES RESPIRATION.

The treatment in the majority of cases will consist in the exhibition of the remedies indicated by the diseased conditions to which this sign is secondary. Rosenbach maintains that the breathing is independent of vascular or circulatory changes, and that it depends almost entirely upon the condition of the nerve cells in the respiratory centre in the medulla. Rabe recommends Morphia in combination with Digitalis in cardiac cases, and Morphia alone in other cases. This drug must be given with great caution in uræmic subjects.

CHILBLAINS.

In the early or erythematous stages, the proper treatment is to bring the circulation of the part to its normal condition by friction with a stimulating liniment. Thus when first noticed, if the chil-

blain is perseveringly rubbed with the following application it soon disappears :—

R Spirit. Camphoræ ℥i.
Tr. Capsici ℥j.
Tr. Cannab. Ind. ℥j.
Olei Cayuputi ℥j. misce.

Fiat Linimentum.

Lin. Camph. Co. is a good application, as is also the following —
Lin. Saponis, ℥ii. ; Chloroform, ℥j. ; Lin. Belladonnæ, ℥i. ;
misce.

With some patients one good application of Liniment of Iodine with a brush is followed by satisfactory results. Arnica should never be used, and Aconite gives relief, but leaves matters worse ultimately. It relieves the itching, and may be added to the last-mentioned recipe. Belladonna liniment painted on also affords relief, and does not interfere with the local nerve supply. Equal parts of Turpentine and Olive Oil, with 4 part of Chloroform, make a good application. Oil of Eucalyptus may be also rubbed in before the skin breaks, and a little Thymol, Menthol, or Salol may be added.

If blebs form, they should be snipped, and the part dressed with the following ointment. —Ungt. Zinci, ℥j ; Tr. Benzoin Co., ℥ii. ; Lanolin, ℥iv. ; misce.

Calamine Ointment, 8 parts, Balsam of Peru, 1 part, is a very good ointment. Plain Basilicon is perhaps the best of all applications at this stage if applied spread upon lint. Flexible Collodion may be used where dressings cannot be worn, and it is best if applied before the skin breaks. A 20 per cent. Ichthyol-Lanoline Ointment makes a very valuable dressing to the sores.

Should the ulcer be tedious in healing, it may be treated as an ordinary sore, and a weak Solution of Chloral Hydrate (5 grs. to 1 oz.) is the best application, or any of the numerous methods and drugs mentioned under Ulcer may be resorted to.

Besnier treats chilblains by bathing the hands in a decoction of Walnut leaves, drying and rubbing in Spirit of Camphor, and dusting over with a powder consisting of Salicylate of Bismuth, 1 part ; Starch, 9 parts.

Vigorous exercise in the open air even in coldest weather should be taken, together with a generous diet, warm flannels, avoidance of heating the hands and feet before the fire, and no hot water bottles in bed.

Ichthyol internally has been recommended, and the writer has proved its value. He has observed excellent results from nine Bland's Pills in the day. L. Jones recommends a strong induced current applied in a hot foot bath at bed-time, for 15 minutes, till a *lasting glow* is produced.

CHLOASMA.

Confining the term to the affection characterised by the presence of pigmented spots (ephelides or freckles) or patches caused by the deposition of pigment in the cells of the rete mucosum, the treatment will be to destroy the epidermis in which they are situated. Hebra's method is to apply a lint compress for four days, soaked in solution of Perchloride of Mercury (1 in 100), letting out the blister formed, and dressing the resulting raw surface with powdered Starch; or 8 grs. of the Mercurial Salt may be dissolved in 8 oz. of Almond Emulsion, and sponged over the spot several times daily till desquamation occurs. Una applies a plaster made with Hydrarg. Ammon. Chlor. for 12 hours, and dresses afterwards with an ointment of Bismuth (1 dr. to 1 oz.). Lincture of Iodine, Carbolic Acid, Sulphurous Acid, Peroxide of Hydrogen, Acetic Acid, and many other mild counter-irritants are also successful.

Crocker uses an ointment of 10 to 20 grs. of Veratrine to 1 oz. lard. Pringle uses Salicylic Acid either as a paste, plaster, or emulsion, or saturated alcoholic solution; Resorcin is also advocated.

Cantharides should never be employed; it increases pigmentation so does mustard. Wilson used Potash Soap and Alkaline lotions. Chrysarobin is efficacious, but, owing to its staining properties, it should never be used when other agents do so well. For simple freckles, Pringle says each may be touched with pure Carbolic Acid, or Electrolysis may be resorted to.

CHLOASMA UTERINUM.—The large pigmented patches on the foreheads of pregnant women, or in those suffering from uterine or ovarian irritation, disappear when the cause is removed, and the patches treated by the weak Corrosive Sublimate and Almond Mixture.

CHLORAL POISONING—See under *Poisoning*.

CHLOROFORM NARCOSIS AND CHLOROFORM POISONING—See under *Poisoning by Chloroform*.

CHLOROSIS.

The treatment of this condition has been referred to under *Anæmia* and *Amenorrhæa*, it may be summed up in the word—*Iron*. Bland's Pills, 2 four times daily, 30 to 60 minims of *Dialysed Iron*, or 5 grs. Reduced Iron are the best preparations. The dose of the metal, in whatever preparation selected, should be large and often repeated. Failure in treatment is owing to the cessation of Iron administration and too small dosage. Allbutt rightly insists that the metal must be given continuously for at least three months, his method is to give 1 gr. Sulphate three times a day for the first week, 2 grs. in the second, and 3 grs. in the third week, .5 grs. being taken daily for two months, after which the dose is gradually lessened.

The constitutional treatment is also mentioned under the above-named conditions. It may now and then, in rare cases, be found that the results of Iron soon cease after stopping its administration, and it will be well to leave off for a period in which Arsenic may be given, or the Iron and Arsenic may be given together.

Albuminates of Iron and enemata of defibrinated blood or oxen have been advocated, but the common experience is that it is not the nature of the preparation, but the amount of the metal introduced into the blood, which is the potent factor in treatment.

Sir Andrew Clarke insisted upon the necessity of giving purgatives, and gave $\frac{1}{2}$ th part of the following twice a day:—Ferri Sulph., 24 grs., Mag. Sulph., 6 drs.; Ac. Sulph. Arom., 1 dr., Tinct. Zingib., 2 drs.; Inf. Gent. Co. ad 8 oz.

The theory that chlorosis is caused by auto-intoxication has led to the advocacy of purgatives and intestinal disinfectants, and the discovery that the mass of the blood is increased has led some physicians to advocate purgatives. The universal experience is that the routine use of disinfectants is unnecessary, and continual purgation decidedly injurious. Iron alone meets all the demands of the condition as far as drugs are concerned. The questions of food, exercise, change of scene, environment, &c., are all discussed under Amenorrhœa and Anæmia, where various formulae are given. When the condition of the gastric membrane resents Iron, the writer gives reduced Iron and Arsenate of Iron in a Keratine-coated pill.

CHOLERA ASIATICA.

There is much difference of opinion about the treatment of this disease. Only those general principles which have been most generally accepted need be detailed.

The importance of prophylaxis cannot be over-stated, and of all points the purity of the drinking water is of vital consequence. Fortunately, boiling and filtration afford perfect protection as regards this source of infection; the addition of even large amounts of alcoholic liquors is useless without heat. All foods and drinks should be quite recently cooked or boiled. Fruits must be most sparingly used, and only those in best condition be eaten. Water for cleansing purposes should be boiled. Rigid isolation of those suffering from the disease, and disinfection of their apartments, linen, and clothing, and free bathing in weak disinfectant solutions are necessary. The excretions from the body should be destroyed instantly, and the greatest personal cleanliness in every respect insisted upon. Everything that lowers the vitality of the healthy, as over-work, fashionable dissipation, irregular meals, &c., is to be guarded against. Diarrhœa, constipation, and indigestion are to be met by appropriate agents without delay in cholera times. The use of astringents like Catechu, Kino, Tannin,

ke, in combination with Laudanum or Chlorodyne is universally approved of for the preliminary diarrhoea.

The recognition of the parasitic nature of the disease has led to the demise of many of the older methods of treatment, and opinion seems growing in favour of plans based upon the destruction of the bacilli whilst in the stomach and intestines, and upon the rapid elimination of the poison which they secrete, symptoms being also treated as they arise. It cannot be said, however, that any real advance has been made in this direction.

Cantani insists upon the bacilli being immediately attacked as soon as the first diarrhoeic symptoms appear. 2 oz. of Tannin are dissolved in 1 gallon of sterilised water, and the solution heated to about 105° F., and injected slowly into the colon through a rubber tube 2 feet long by the pressure of a reservoir placed 4 or 5 feet above the patient; by gentle massage of the right iliac fossa he is quite satisfied that the fluid may be made to flush out the small intestine, in some instances as far as the stomach. This enteroclysis not only acts as an intestinal disinfectant, but by its temperature prevents collapse. It may be repeated every 2 hours, and children 2 years old may have 1 pint of the solution injected. Some authorities also wash out the stomach with the solution at the stage. Upon the same principle of antiseptics and elimination large doses of Calomel and Castor Oil are recommended.

Various antiseptics have been landed—Salol, Camphor, Carbolic Acid, Creosole, Thymol, Perchloride of Mercury, Naphthol Bromel, Salicylic Acid, Pyoktannin, Creolin, Cresol, Chlorine Water, and Iodoform.

But it may be safely affirmed that there is as yet no drug introduced which materially lowers the mortality satisfactorily. The result of the Hamburg epidemic showed that all antiseptics were rejected for Calomel—"the only drug which held its own." Salol failed completely. An old remedy Copper Sulphate, is lauded and Ammonio-tetrasulphate of Potassium, with the view of acidifying the intestinal contents, is strongly urged.

As soon as any symptoms of collapse appear fluid should be introduced into the circulation to dilute the concentrated state of the blood. Large hypodermic doses of sterilised Saline Solution (10 grs. Sodium Chloride and 30 grs. Sodium Carbonate dissolved in 40 oz. water) may be injected at once by a siphon reservoir raised 4 or 5 feet above the patient and the needle of the aspirator may be employed for this purpose, and the skin of the thighs or hypochondriac regions being selected, and the absorption hastened by gentle massage. Abbot speaks highly of this plan of Hypodermoclysis when combined with the rectal injections mentioned above, both agents being repeated till the pulse and temperature respond. In urgent cases the Saline Solution may be injected slowly into the veins of the arm, and 80 to 100 oz. may be so used.

Opium in large doses in the early and second stage, is now generally condemned, the view being accepted as correct, which

opposes anything favouring prolonged retention of the ptomaines in the intestine. The drug may be given in small doses hypodermically to relieve pain, shock, and cramp.

The treatment of the various symptoms during the third and convalescent stages is to be carried out on general principles.

Hypodermics of Quinine, Strychnine, Atropine, Pilocarpine, and Cocaine have been used to meet collapse and various supposed actions of the ptomaines. Oxygen Inhalation and blistering over the vagi have their advocates.

Preventive inoculation for cholera has been extensively tried in India by Haffkine, who injects by the gradually intensified method cultures of the comma bacillus. This method has been tried under the superintendence of Surgeon-General Harvey at Gya Prison, with most striking success. Inoculations have been made in perhaps 100,000 cases and as far as the writer's knowledge goes, without a death. The immunity is not, however, complete and it probably only lasts for about a year.

Several observers testify to the value of Kitasato's serum in the treatment of Cholera, but the results are not very conclusive.

CHOLERA INFANTUM—See Diarrhoea.

CHORDEE—See Gonorrhoea.

CHOREA.

Of the host of remedies recommended from time to time for the treatment of chorea only three or four are of real value. A disease so liable to get well in many cases if left to itself is certain to have scores of specifics and whatever drug the observer had chanced to give, he is liable to attribute the spontaneous cure to its influence. Whilst many cases of chorea will recover if left alone without any medicine whatever, it is equally certain that many will go on from bad to worse if not treated. It is also certain that we have drugs which if judiciously administered, possess the power of arresting the disease.

Rest in bed, suitable clothing, ventilation, cold sponging, good food and abundance of it carefully administered, will go a great way to effect recovery. Absolute rest in bed and freedom from all excitement is essential in bad cases. Where there is reason to suspect that reflex causes, errors in refraction, dental caries, nasal troubles, &c.) may be a factor, these should be removed.

Often the condition is associated with anaemia, and when this is remedied the chorea passes off. It will be wise, when a mild case comes before the physician for the first time, at the very commencement of the symptoms to attend to rest and feeding, and abstain from very active drugging. A small quantity of Tincture of Iron with Cod Liver Oil, cannot fail to improve the general health when associated with a few mild doses of a saline purgative. If the movements, however, have lasted for any time—a week or more—the patient should at once be placed upon a course of Arsenic

From a very extensive experience of chorea in a children's hospital, the writer has thoroughly satisfied himself about the great value of this drug in this affection, and he believes that the failures are owing to a mistake in the dosage.

Choreic children bear larger doses of Arsenic than would, at first sight, seem possible. These large doses are also necessary to produce an effect upon the disease. Given in the ordinary doses, say of 1 minim of Fowler's Solution for a child 3 or 4 years old, or of 2 or 3 minims for a child of 6 or 7, Arsenic probably produces little or no benefit, and the writer has seen several cases where no drug was said to have failed which have rapidly improved when the proper dose was administered. Something very like this has been seen in the treatment of anemia and chlorosis with small doses of Iron. It is a well-established fact that these affections may be for a long time treated by ordinary doses of some iron preparation without any appreciable benefit, but almost immediately improvement is noticed after the administration of large doses—doses much larger than can possibly be assimilated. The writer gives up to 25 or 27 drops of Liquor Arsenicalis after each meal in a large tumblerful of Alkaline Water in divided drinks during the hour following the meals. Where the stomach is unable the drug may be given hypodermically. Rarely have any side-effects been recorded, but the physician should be on the watch for excitation and signs of neuritis.

For a child of 7 years old, with choreic movements, Fowler's Solution may be commenced in doses of 3 minims three times a day, and the dose may in a week be brought up to 10 minims three times daily without producing any untoward symptoms, and this dose can be taken for many weeks. Should improvement be very slow the Arsenic may be pushed till griping and indigestion, or signs of irritation of the conjunctiva or nasal mucous membrane, show themselves. Iron may be combined with it, but not in doses proportionately large, and it should always be given after a meal. The following is a good working formula:—

R. *Liq. Arsenicalis (Fowler) ℥ss.*
 Tinctura Ferri Perchlor. ʒij.
 Glycerini Purificati ʒi.
 Aqua Chloroformi ad ʒiv. misce.

Fiat mist. Capiat ʒi. ter in die ex aqua post cib.

Carodylate of Soda has already been extensively used in the treatment of chorea. It can be given hypodermically, if necessary, or in the pill form in doses 10 times greater than the oxide of Arsenic.

In the great majority of cases no further treatment will be required. Next to Arsenic comes Sulphate of Zinc. It is not safe

to give out bottles containing large quantities of Arsenic amongst the promiscuous crowds of the extern department of a children's hospital, and here it is well to have a remedy at hand which, if swallowed by mistake in large quantities, will not cause fatal results. Beginning with 2 or 3 grs., rapidly increased to 8 grs., the effects of Sulphate of Zinc are well marked, and it is rather surprising to see how soon the stomach becomes accustomed to large doses without producing nausea. It should be given in solution immediately after a meal, and four times a day. The Sulphate of Copper and Nitrate and Oxide of Silver appear to act in the same way, but they have no advantages over Zinc Salt, and are even more dangerous than the Arsenic if swallowed in large quantities by mistake. Other remedies used occasionally with benefit are Apomorphine, Lobelia, and Tartarated Antimony, given in doses to produce nausea bordering upon vomiting.

Bromides of Potassium, Ammonium, Sodium, and Zinc in full doses to allay nerve excitement have proved useful, and Gouber gives the Bromide of Gold in doses of $\frac{1}{8}$ gr. till sleep comes on. As a rule, however, even in cases associated with hysteria, the treatment of chorea by Bromides, in the opinion of the writer, is not worth trying.

Actea, Iodides, and Salicylates may be employed in cases where the attack is obviously associated with acute rheumatism. The first-named remedy has been much praised, the writer believes, without possessing any decided merits. Some rheumatic cases have been treated successfully by external applications of Oleum Gaultheriae, and it is maintained that it is efficacious in cases which are not associated with rheumatism.

Phosphide of Zinc ($\frac{1}{8}$ gr. for a child 7 years old) and the Valerianate of Zinc (in $\frac{1}{2}$ gr. doses) act somewhat like the Sulphate, but less satisfactorily. The Bromo-valerianate is much more reliable. The Oxide may be given in doses as large as the Sulphate.

Strychnine was recommended highly by Troisseau, who gave it in gradually-increasing doses till mild symptoms of poisoning began to show themselves. It is stated to be still the best remedy for chorea caused by a fright, but in the writer's experience a history of fright is to be found in very many cases of the disease. The drug is valuable in the later stages when muscular weakness is observable.

In the very severe cases of acute chorea, threatening seriously to cut short the little patient's career from the exhaustion caused by the ceaseless movements of the limbs and body, a different set of remedies must be employed. Here, to wait for the action of Zinc, Arsenic, or Iron is out of the question. It is in these comparatively rare cases that the remedy recommended by Harley is indicated. He gives Commu Juice in large doses till the physiological effects are observed. Kinger gave "to a child" seven drachms of the juice every hour, unless when asleep. Unfortunately the effect of the drug is not lasting, but the writer

was able in more than one bad case to keep the patients alive till Arsenic had time to act. The hot pack at bed-time will be beneficial in these cases.

Chloral is of the greatest use in these cases in gradually-increasing doses. A child 7 years old might be cautiously started upon 3 gr. doses. Gardner mentions an interesting case of a girl aged 8, who was taking 15 grs. three times daily. She then got 60 grs. by mistake, and though her life was in great danger, she recovered, and the chorea was cured. He states that it has an almost absolute power of suspending or controlling spasms during the persistence of its deep hypnotic action.

Some authorities successfully treat chorea in a routine way by Chloral, giving sometimes a gram for each year of the child's age.

Bastian has treated several cases by keeping the patient asleep for several weeks, except for half-hour intervals, during which she was fed. This appears to the writer to be a very questionable method of proceeding with a dangerous drug. Lichtschein has recently revived this continuous sleep method, and to a girl of 12 years gave daily doses of 120 grs. for twenty days, which kept her in a continuous, deeply somnolent condition, after which she perfectly recovered on awaking, having gained over 13 lbs. in weight. Chloral may be combined with other drugs, and in a very severe case, with exhaustive movements, in a child 6 years old, the following may be given -

R. Chloral Hydratis ℥ii.
Sodu Bromidi ℥iij.
Succi Conii ℥ii.
Aqua et Syrupi ad ℥vi. misce.

Fiat mistura. Capl. ℥ii. quartis horis.

Belladonna and Hyoscyamus may be tried. Excellent results are sometimes obtained by the hypodermic use of Hyoscyne Hydrobromate in doses of 1 to 2 gr. in grave cases. In a few cases Cannabis Indica has given rest, more frequently it is useless.

In desperate cases the vapour of Chloroform may be inhaled, and if sleep supervene without cessation of the movements, it may be continued at short intervals cautiously. Ether may be given. Antimony has occasionally given rest in these acute cases, but it interferes seriously with appetite and digestion, and it is of vital importance to sustain life by stimulants and good feeding.

Curara has been employed in doses of $\frac{1}{16}$ gr. hypodermically for a child, and though it is doubtless a remedy of some value, its effects are very evanescent, and they cannot with safety be kept up for any length of time.

Physostigma in powder, extract or alkaloid, has been tried, and is open to the same objections as the previous remedy, so that upon the whole it is doubtful if its administration is justifiable.

$\frac{1}{16}$ gr. of Physostigmine for a child 7 years old may be given hypodermically every four hours, and Reiss claims that he cures chorea with Eserine hypodermically in five or six days. His dose is $\frac{1}{16}$ gr. twice daily.

Ether Spray applied along the spine is not open to any objection, and sometimes produces refreshing rest in severe cases, and should always be tried. It is better than cold douches and the spinal ice-bag. Methyl Chloride Spray has been also used.

Morphia hypodermically may be given to induce sleep, but the greatest caution should be exercised in treating children in this way, and the writer would be slow to ever try it, though Troussau advocated opium in doses sufficient to produce constant drowsiness as a routine method of dealing with the disease.

Trional and Sulphonal are perfectly safe, and may be given in full doses. Moreover, they have been given as routine remedies for the disease with some show of success, even where sleeplessness was not a feature. As just mentioned, Chloral or Chloralamide may be resorted to when insomnia is present.

Antipyrine and Antifebrin have been tried, both in the mild and grave forms of chorea, occasionally with marked success, and their effects may safely be tried where the better known remedies fail. Antipyrine may be given in 2 gr. doses every three hours to very young children. Some authorities push the drug till 100 grs. are given daily.

Wood advises large doses of Quinine. Static electricity has been used but its value has yet to be established. General galvanism has occasionally given good results, but the strong, interrupted currents recommended by some writers are not to be sanctioned.

Restraint of the excessive movements, when judiciously carried out by a skilful nurse, and proper bandaging of the upper limbs to the trunk, and the lower extremities to each other, often gives some relief in the grave affection. Should it increase the patient's discomfort, it should not be persisted in. It is advisable to watch for bed sores, and often it will be necessary to protect prominent joints or bones by a padding of wool and bandage.

Heart complications may require attention, but unless these be of old-standing it is not good practice to begin pouring in full doses of Digitalis and Strophanthus.

Cod Liver Oil is useful at all stages of the disease, and during convalescence, when the movements have ceased, moderate exercise, massage and gymnastics (Swedish movements) may be indulged in with advantage.

Treatment is of little avail in the rare cases of chronic, progressive, senile, and hereditary choreas, but much may be done to relieve the patient upon the lines already sketched out in dealing with severe cases of the ordinary malady. Some authorities seriously believing in the infectious nature of chorea go so far as to recommend isolation.

CHOROIDITIS.

If of syphilitic origin, will yield to active Mercurial treatment, and in an early stage, mercurial inunctions are especially indicated and should be continued for a considerable period. In acute cases occurring late in syphilis, large doses of Iodide of Potassium may be tried next. In acute or sub-acute cases, where sight has recently been failing from areolar or diffused choroiditis, where no history of syphilis is obtained, and where the kidneys are sound, the hope lies in small doses of the Perchloride of Mercury ($\frac{1}{2}$ gr. four times a day, commenced after a brisk saline purgative. Blood letting by leeching of the temples, followed by the application of a small cupping glass, or preferably by the use of Heurteloup's leech, should be at once resorted to and any deviation from the standard of health attended to. Absolute rest to the eyes must be insisted upon. Pilocarpine hypodermically, in doses of $\frac{1}{4}$ to $\frac{1}{2}$ gr. is the best remedy where recently-effused products have to be dealt with.

For the chronic disseminated choroiditis, chiefly observed in children, the off-spring of syphilitic parents, little or nothing can be done, unless there chance to be some recent or active inflammation going on. Generally the defect in vision is only noticed after the active stage is passed, and when the period has expired during which treatment would be of any use. The necessity of treating every departure from the normal standard of health in such subjects need hardly be referred to.

Much has been written regarding the value of sub-conjunctival injection of Bichloride or Cyanide of Mercury in various eye affections. It causes smart pain and reaction, which may be lessened by adding Acon to the solution for injection.

CHYLURIA

Has yet to be satisfactorily treated. No remedy appears to possess any constant effect upon the appearance of suspended fatty matter in the urine, generally caused by the presence of filaria in the blood and lymphatic vessels. The best results are obtained by prolonged rest in the recumbent position with the pelvis raised, and a diet free from fats and albuminoids.

Benefit is obtained for a short time by decoctions of the bark of *Ehretophora Racemosa* (the mangrove), or preparations of the seed of *Nigella-Sativa*. Benzoic Acid and Benzoate of Soda may be tried. Gallic Acid in 1 to 2 drachm doses affords some benefit, and large doses of Tinct. Ferri Perchlor. do some good. Antiseptics have failed, though Yeo reports that Thymol in 1-2 gr. doses soon caused disappearance of the filaria, but large doses of Iodide of Potassium, and of Syr. Ferri Iod. appear to have checked the discharge for a time in several cases.

Manson states that he has seen no benefit from any of the above-mentioned drugs.

CLEFT PALATE

Can, of course, only be satisfactorily dealt with by an operation. As a rule, this should not be undertaken, in cases where the soft palate is alone involved, till the patient is past the period of the first dentition. About 2½ years of age is a good time. Where the hard palate is involved in the cleft, about double this age is the best period for operative interference. Chloroform can be safely given.

The uvula being caught firmly with forceps, the margins of the cleft in the soft palate are carefully pared. Silver or silkworm gut sutures being passed, the margins should be approximated. If there be much tension, an incision should be made a short distance outside the cleft on each side, and parallel with it, to allow of accurate adjustment of the pared edges without undue tightness of the sutures. Where the fissure extends to the hard palate, an attempt can, at the same time, be made to close it also.

The periosteum being dissected from the bone on each side of the margin of the cleft through incisions parallel to the cleft, and some little distance outside it, the edges of the muco-periosteum are sutured and brought into position, as in the case of the soft palate. The most careful feeding and nursing are required. The sutures may be removed about the eighteenth day.

In cases where the condition has been neglected, and the patient first presents himself for the treatment of a cleft in the hard palate in adult life, the operation of Sir Wm Ferguson may be decided upon. But the writer would say, after witnessing Sir William perform the operation in 1874, that it should not be entered upon without serious consideration. The perforation, and subsequent chiselling and detachment of the segments of bone make it a most protracted and bloody operation, and not always followed by success, and if success be achieved, one may well question "if the game be worth the candle."

Such a case may be made comfortable for the remainder of the patient's life by having a gold or thin vulcanite plate accurately adapted to the roof of the mouth, covering the fissure, and having an artificial tympanum or soft palate of India-rubber attached behind. The obturator may carry any artificial teeth to fill gaps in the row of incisors, and it may be attached to the sound molars.

Davies-Colley removes a long, narrow flap of the muco-periosteum from the side of the palate to which the septum is attached, and closes the cleft by carrying it across to the narrow side and fixing it with sutures.

The after-treatment of cleft palate is of vital importance, and Erichsen advises that the stitches should be kept in for three or four weeks, and that the wound should not even be inspected for the first seven days.

CLUB FOOT.

The treatment of the different varieties of this affection is carried out by various surgical procedures, whose object is to overcome the contractions or shortenings in the muscles upon one aspect of the limb while upon the elongated side of the affected leg or foot attempts should be made to increase the strength and tone of the muscles and other structures. Tenotomy will only be required in the severer forms of the deformity. If the foot can be easily brought into its natural position by flexion or extension without the use of any force, permanent removal of the deformity may be achieved by careful and frequent extension of the contracted tendons and massage of the weakened muscles upon the opposite aspect of the limb, carried out several times a day by a skilful nurse.

Where some force is requisite to get the foot into the normal anatomical position, and keep it there, it will be necessary to secure it in this position by strapping, so applied as to counteract the tension exercised by the shortened tendon. If the necessary force be greater than strapping will afford, a simple splint, with a moderately firm bandage, may accomplish this.

Many paralytic cases of club foot will yield to these measures, and the writer has had very satisfactory results by injecting small doses of Strychnine into the weakened muscles in cases following poliomyelitis anterior acuta. Galvanism, a weak interrupted current, or a strong continuous one, will sometimes restore power to muscles when they have apparently disappeared altogether, but the remedy must be persisted in for a long time.

In congenital cases the extension and massage should be commenced as soon as the affection is recognised. If these measures fail to produce decided improvement, or if the strong force required to bring the foot into its position convinces the surgeon that these measures are inapplicable from the first, the contracted tendons should be divided with a tenotomy knife simultaneously, and the foot in its deformed position should be bandaged to a splint for a few days to keep the divided ends of the tendon from separating. Gradual extension by means of a Scarpa's shoe may be commenced after some uniting material has been poured out between the cut ends of the tendon.

The different varieties of talipes will, of course, require division of different tendons when they fail to respond to simpler treatment, and the different examples of each variety may demand different operations, thus for equinus the tendo Achillis may only require division, whilst in another case the plantar fascia must be incised also.

The congenital equino-varus presents considerable difficulty in its treatment. It is best to remedy the varus, and afterwards divide the tendo Achillis. The first object is achieved by tenotomy of the *musculus anticus, tibialis posticus, and flexor longus digitorum*. After treatment by extension for five or six weeks, the plantar fascia and tendo Achillis are divided, and a suitable boot and

appliance, made by an instrument maker, adjusted to the limb, by means of which stretching of the contracted tendons may be kept up for many weeks, massage and passive movements being continued daily for months afterwards. The other varieties of talipes are treated upon the same general principles, always remembering that after tenotomy operations the mechanical stretching of the divided tendons must be kept up for a long time.

As soon as the child inclines to walk splints must be provided, with pelvic girdle and joints at knee and ankle, and these must be worn for two or three years, otherwise the deformity is almost certain to return.

Ogston, relying upon the cause of club foot being an arrest of the foetal unwinding of the limb, which affects all the structures of the foot and leg, denounces, as most unscientific, the division of a tendon in its sheath "for no union between its divided ends is possible, and anything more useless in treating ordinary club foot could scarcely be named. Promiscuous tenotomy is both unscientific and unnecessary." He approves of Huter's method of keeping the limb in a rectified position (after manipulation by the hand, under chloroform) by means of a fixed bandage of Cafferlati's best Plaster of Paris (as being better, because requiring less skill and patience than splints), elastic traction, and other apparatus.

The plaster splint is applied at about the age of six weeks by means of book-muslin plaster bandages, applied *direct* to the skin, the limb being held in as near the normal position as is possible by plaster loops till the bandage is applied, and till the plaster sets. He permits these to remain on for six weeks. The varus position should always be corrected before touching the equinus. For this he always divides the tendo Achillis, and applies the bandage from the foot to half-way up the thigh, with the knee extended. In older cases the choice lies between cuneiform excision of the tarsus, linear osteotomy of the tarsus, or Lund's excision of the astragalus or osteotomy of the tibia or fibula.

COCCYDYNIA.

Sir James Simpson's operation of subcutaneous section of the coccygeal muscles is the only remedy for this most obstinate affection. Where this operation fails, Notts' practice of excising the coccyx will also generally be found to fail. Some relief may be obtained by wearing a Belladonna Plaster, cut to the shape of the parts, and terminating in a pointed end or tail, which covers the skin over the lower part of the sacrum and coccyx, coming forwards to near the anus. Any local anæsthetic may be employed from time to time to give temporary relief, and occasionally benefit is derived from the application of a blister or counter-irritant, like the liniment of Iodine, or Corrigan's Iron.

Ménière uses the following suppository at bed-time :—

R. *Extracti Belladonnae* gr. $\frac{1}{2}$.
Extracti Hyoscyami gr. $\frac{1}{2}$.
Iodoformi gr. $\frac{1}{2}$.
Olei Theobromatis gr. xx. misc.

℞ Chloral Hydrat., $1\frac{1}{2}$ grs.; Extract. Valerianæ, $1\frac{1}{2}$ grs.; Olei Theobromatis, 20 grs.

COLIC, Biliary—See Gall Stones.

COLIC, Intestinal.

The cause of the attack will often afford the best indication for the nature of the treatment required. Thus the colic of infancy generally depends upon an error in feeding, and in the majority of cases will be found to depend upon the presence of indigestible milk curd, which, if not speedily remedied, may give rise to rapidly fatal enteritis. A smart purge (1-2 drs. of Castor Oil), combined with carminatives and a change of diet, will give permanent relief. If the milk of the mother or a healthy wet nurse is not available, Benger's or Nestle's Food is decidedly the best and nearest port in the storm in cases of severe intractable colic in infants.

The minor attacks of infantile colic should never be treated by Laudanum. The Oil of Anise 1 to 2 drops on sugar, may be given every hour. Peppermint is more suitable for children and adults. Dill Water, with a little Magnesia, is a favourite domestic remedy.

R. *Magnes. Carb.* gr. xx.
Syrup. Zingib. ℥ii.
Spt. Chlorof. ℥xx.
Aquæ Anethi ad ℥iii. misc.

Fiat mistura. Sumat ℥j, *omni hora si opus sit.*

Yer's favourite formula is Gregory's Powder, 1 dr.; Fetid Spirit of Anamoni $\frac{1}{2}$ dr., Tinct. Card. Co., 3 drs., Spt. of Chloroform, 9 dr. Caraway Water to $1\frac{1}{2}$ oz. 1 to 2 drs. every hour.

In adults, if the colic depends upon the presence of any fermenting, or indigestible, or fermenting food, a smart purge with opium combined should be given. Castor Oil is the safest of all cathartics in such cases, as there is always the remote possibility of some abdominal mischief lying behind the attack.

The following is a well-tried formula:—

R. *Ol. Ricini* ℥v.
Tinct. Rhei Co. ℥ii.
Tr. Opii ℥xx.
Aquæ Cinnamomi ad ℥iii. misc.

Fiat haustus statim sumendus p. p. a.

6 grs. Calomel with $\frac{1}{2}$ gr. Morphia may be placed upon the tongue if vomiting is present, or $\frac{1}{2}$ gr. Morphia may be given in suppository after a large warm water enema. Before the cathartic acts the patient may be put into a hot bath (T. 104°), and a large Linseed and Mustard Poultice applied to the abdomen after he is put to bed. Hot Turpentine stipes may be used instead of hot bath. The ordinary India-rubber bottle, filled with hot water and laid against the stomach region, affords great comfort in a case.

Should the pain continue unrelieved, a hypodermic of $\frac{1}{4}$ gr. Morphia, with 1 minim of the P. B. Solution of Atropine, may be given in conjunction with a glassful of hot punch. Chloroform has been administered where the suffering has been acute, but in simple colic it must be seldom required. The following may be tried in chronic cases, or where the attacks recur:—

ASAFOETIDA—The tincture, or fetid spirit of ammoniac, in doses of 1 drachm.

SAL VOLATILE—In tea-spoonful doses, largely diluted or, combined with whiskey or brandy.

ETHER—In tea-spoonful doses of the spirit, or of Hoffmann's Anodyne, or even tea-spoonful doses of the pure ether angelic be given alone or in a little spirit.

BELLADONNA—15 minims of the tincture may be administered at one dose.

GINGER OR CARDAMOMS—In tea-spoonfuls of the tincture diluted.

ESSENTIAL OILS—Cajuput (5 minims), Chamomile (3 minims), Peppermint (5 minims), Cinnamon, Cloves, or Caraway (3 minims), or Camphor (5 grs.)—every two or three hours.

NUX VOMICA is much praised; the writer never saw it give relief.

COCCULUS INDICUS, from which Picrotoxin is obtained, is said by Brunton to relieve colic in pregnancy. Each of the above will do likewise without any of the dangers attending the use of this drug.

CHLORODYNE—15 to 30 minims—is a popular remedy of great power and certainty of action.

COLIC, Lead.

A smart purgative should be given at once when the patient first comes under observation. 1 oz. Sulphate of Magnesia is the most suitable. Castor Oil acts satisfactorily, but the Sulphate can be repeated every 3 hours in tea-spoonful doses if the first dose fails to act, whilst repeated doses of the oil cannot be tolerated. Should the pain be severe, any of the remedies mentioned upon the previous page may be administered with the view of giving temporary relief. After the evacuation of the bowels the patient

should be put upon a course of Iodide of Potassium to cause elimination of lead from the system. This course may be well supplemented by a morning purge caused by the Sulphate of Magnesia, the rationale of the treatment being to attack the insoluble lead stored up in the system, convert it into the soluble iodide which is eliminated by the urine and by the mucous membrane of the intestinal tract, and then by meeting this in the intestines it is rapidly converted into the less soluble sulphate and at once thrown out by purging with the Epsom Salt before it has time to be re-absorbed.

Combemale and Weill have had great success in the treatment of lead colic by large doses of Olive Oil. In addition to its laxative properties, doses of 5 oz. seem to possess some striking analgesic effect, so that constipation and pain pass off in a few days. Where the oil is vomited, 2 or 3 grs. of Thymol given before the next dose generally suffice to prevent this.

Diluted Sulphuric Acid, in 20-minim doses, may be taken in half a tumblerful of water as a drink frequently during the day, or Lemonade made with Sulphuric Acid instead of citric and tartaric acids, as ordinarily employed by lemonade makers. This beverage is a valuable prophylactic, and may be given with the same in bad cases.

Alum, in full doses, sometimes purges in the obstinate constipation of lead colic, and it is also said to relieve the pain when purging does not occur. It may be given in doses of 20 grs.

Sulphur, Onions, Garlic, Eggs, Harrogate Water, and other sulphur-containing bodies have been used successfully with a view of causing elimination. Sulphur baths have been recommended for the same reasons, and a diet of milk in large quantities favours convalescence. (See also under Plumbism, where the prophylaxis is fully discussed.)

COLIC, Renal—See Stone in the Kidney.

COLITIS.

The treatment in simple cases resolves itself into the treatment of the diarrhoea and pain which are the prominent symptoms. Large doses of Bismuth Carbonate, suspended in freshly-made mangel, combined with small doses of Laudanum may be given by the mouth, whilst the same mixture may be injected into the rectum. Once a day the colon may be washed out with weak Condy's Fluid or Boric Acid Solution. A restricted fluid diet, consisting of milk and lime water, and rest in bed is advisable. Tannalbin may be given in 15 gr. doses where the diarrhoea is profuse.

Membranous colitis should be met by a vigorous dietetic and drug treatment directed to the relief of the dyspepsia which is generally present. In severe cases the only remedy may be found in a right colotomy with closure of the artificial anus after 6 or 9 months.

In ulcerative colitis the best procedure is to flush out the colon with a strong Boric Acid Solution daily, or oftener, and in intractable cases to inject 10 grs. Nitrate of Silver in two pints of water after the Boric Solution has washed away all mucus and blood. Colotomy may be required, with subsequent flushing out of the colon with Condy's or Boric Acid Solution allowed to flow out of the anus.

COLLAPSE (and Shock).

The most obvious indication in the majority of cases of collapse, from whatever cause, is to attend to the condition of the heart. The horizontal position must be enforced, and the falling body-heat corrected promptly by warmth to the surface at every point with hot blankets, water bottles, and gentle friction. The cutaneous circulation, and, reflexly, the circulation in other parts, should be stimulated by mustard to the spine, nape of the neck, and calves of the legs. Brandy or whiskey punch should be given if the patient can swallow; if not, these remedies must be administered by the bowel or by hypodermic injection though this latter method is very objectionable owing to the bulk of the necessary amount of alcohol. Should the hypodermic method be the only available route in desperate cases, then diluted Ammonia (weak solution or Sal Volatile) should be injected under the skin or into a vein. Ether may be substituted with advantage.

Digitalis, Strophanthus, Belladonna, and cardiac stimulants of this class are employed, but their action is too slow to be relied upon in emergencies. Ammonia to the nostrils is a much better remedy. Hypodermic injection of $\frac{1}{2}$ gr. Strychnine acts rapidly upon the failing heart. Electricity may be applied to the phrenic nerve or an interrupted current may be sent through the upper extremities. Liebig's Extract in large doses with hot water is a rapidly acting stimulant.

Should the collapse or shock be associated with extensive hæmorrhage, subcutaneous injections of warm Saline Solutions, or transfusion may be performed (see page 40); or a temporary ligature or tight bandage may be applied to the thighs to prevent the blood entering the lower extremities; or, what is much better, an Esmarch's elastic bandage to the limbs, or a tourniquet applied to the femoral artery may be tried.

If a serious operation must be performed, unless there be hæmorrhage going on, the surgeon should wait till reaction symptoms are positively established, but he should not wait too long. If he operate during the stage of acute collapse, death will probably ensue, whilst if the operation be performed after the establishment of complete reaction, the shock of the operation may cause a fatal second collapse. (See Syncope and Concussion.)

• In extensive injuries, as bad compound fractures and gun-shot wounds, the surgeon will occasionally meet with cases where the

shock will not pass away till amputation be performed, but the decision to operate is always a very serious one.

Hue and Horsley have drawn attention to the frequency with which the respiratory function is arrested in traumatic shock and they insist upon the importance of performing artificial respiration.

COMA.

Treatment is useless unless the physician can form some idea of the cause of the coma or deep stupor. Thus a head injury, meningeal inflammation, apoplexy, sun stroke, opium or alcohol poisoning, uræmia, or hyperpyrexia may be the cause, and should be promptly met by the treatment as detailed under the heading of the individual primary affection.

Thus the large dose of Calomel given to an apoplectic patient, may cause the death of a patient seized with coma from diseased stomach if administered to him. To treat the coma of opium as one would treat the profound unconsciousness caused by hyperpyrexia, would be to allow the patient to speedily pass beyond the reach of remedies.

Where no evidence whatever can be obtained of the cause of the coma, say in a subject picked up in the streets, Sinapisms may be applied to the back of the neck, spine, abdomen, or back of the legs. If there be even a suspicion of poisoning, the soft tube of the stomach pump should be passed, and the contents drawn off and examined. No harm can come from such procedure, whilst, should the patient die without this having been done, and subsequent information be forthcoming at the coroner's court, serious blame will be meted out to the attendant, even though pumping would have been useless. The writer has often got valuable information by using the catheter in such cases and examining the urine drawn off.

A smart purgative—one drop of Croton Oil—is the safest, and can do no harm, often the Cold Douche may be used. (See the treatment of each of the primary affections under its own heading, *viz.*, Apoplexy, Uræmia, Poisoning by Opium, Alcohol, &c.)

CONCUSSION.

The treatment of the condition spoken of as concussion of the brain may be best managed by carrying out the suggestions made under the head of Collapse. The violent shaking, causing the shock to the patient's nervous system, is best met by absolute rest and quiet. Stimulants should not be given unless the collapse be very alarming. If reaction be ushered in by a hot skin, flushed face and diminished pupils, ice to the shaven head, a smart purge, a darkened room, and complete rest for 2 or 3 weeks, will be advisable. (See Collapse.)

CONDYLOMATA.

Cleanliness, and the free pencilling over of the patches with acid Argent. Nit., or the Acid Nitrate of Mercury Solution, and

afterwards dusting with a powder consisting of equal parts of Calomel and Calamine, is the best treatment for these troublesome growths.

Chromic Acid (1 to 5 of water) speedily destroys mucous patches in the mouth and on the tonsils; it must, however, be used sparingly, as its poisonous effects, when absorbed, are well known. Corrosive Sublimat (1 in 250) is safer and quite as efficacious, but the writer does not hesitate to dry the patch carefully with blotting-paper and apply a light swab of Permanganate of Mercury Solution even to the tonsils, taking great care that the liquid cannot possibly flow over the surface. Bangs recommends one of the following to be painted on daily:—

R. *Hydrarg. Bichlor.* ʒj.
 Collod. Flex. ad ʒj. *misce.*

Or, *Acid. Salicylic* ʒj.
 Collod. Flex. ad ʒj. *misce.*

Iodoform may be freely dusted upon those appearing on the vulva and about the anus, or wherever there is much moisture.

Nitric and Carbolic Acids may be used as caustics, whilst the strongest Zinc Chloride Solution will rapidly destroy external patches, and a weak lotion of the same (10 grs to 1 oz.) makes a good astringent dressing for after-treatment.

The non-specific patches of long standing may be freely cut off with a knife or scissors after the application of Cocaine, and a subsequent application of any strong caustic will stop all hæmorrhage, and destroy anything left by the cutting instrument.

CONJUNCTIVITIS.

The milder and more common form of simple or catarrhal conjunctivitis is best treated by any mild astringent lotion, as—

Zinci Sulphatis gr. x. *Aqua Rosæ* ʒviij. Or,
Acid. Boracici ʒi. *Aqua Rosæ* ʒviij. Or,
Aluminis ʒi. *Aqua Destil.* ʒx. Or,
Zinci Chloridi gr. iv. *Aqua Destil.* ʒviij. Or,
Argenti Nitratis gr. v.—gr. xx. *Aqua Destil.* ʒviij.

These lotions can be best applied directly to the conjunctiva by the small douche glass made to fit to the margins of the orbit, and half filled with the solution; by nodding the head, the conjunctival sac is thoroughly cleansed, and if the lids are kept open every part is brought into contact with the remedy. Pain and photophobia may be relieved by Ice Compresses and the instillation of Atropine or Cocaine, but great care must be taken before using these drugs to ascertain that there is no tendency to glaucoma. It is safer

not to use them in patients past middle age unless they are absolutely necessary. When the case does not yield in a few days to astringents, the lids should be everted and the whole conjunctiva brushed over with the Nitrate of Silver Solution. If a stronger solution than 10 grs. to 1 oz. is used the surface should be rapidly swabbed with a solution of common salt, or with tap water, to neutralize excess of silver before it comes in contact with the cornea. In all cases Vaseline or a simple ointment should be rubbed on the margins of the lids at night, to prevent them sticking together in the morning.

SWAAY uses the following solution, of which a drop is to be instilled morning and evening :—

R. *Acid Boracici* gr. iv.
 Zinc Sulphatis gr. ii.
 Tinctura Opii ʒj.
 Aqua Destillata ad ʒj. misc.

It would be remembered that some forms of the affection are highly contagious, and the most careful isolation is necessary sometimes to prevent its spreading in schools. Towels, basins, nap, brushes, &c., should be carefully cleansed before being used by children free from the disease. The writer has seen a large school of young children affected in this way. Where one eye is affected, and it does not soon yield to treatment, a careful search should be made for a foreign body lying in the conjunctival sac. In small children this will sometimes be found, generally in the form of a bristle. A general anæsthetic may be necessary.

STROMBO'S OPHTHALMIA is the name by which an affection like the above is known when it attacks scrofulous and badly cared for children, the cornea, or corneal margin, being affected as well as the conjunctiva. Generally polycetenuar ulcers exist, and there is more redness, swelling, pain, and photophobia. Cleansing with simple Boric Acid Lotion should be the first step in every case. When photophobia exists, Atropine may be used, but not for more than a very few weeks. Counter-irritation, by Iodine ointment or blistering on the temples, is often of service. Strict injunctions should be given that the child should have regular meals at regular hours, no scraps between times, and exercise in open air, and should not be allowed to lie on its face with its head buried in a pillow, as it will probably wish to do. When it does its eyes may be shaded by dark glasses or a broad white covering both eyes, but allowing the patient to see under it, at the peak of a cap.

Pagestecher's Ointment—30 grs. of Yellow Oxide of Mercury to 1 oz. Vaseline—should be smeared across the margin of the everted lid. Half the ordinary strength of this ointment is better for children, or 4 to 6 grs. to 1 oz. if it is to be used at

home. Like all eye ointments, if not carefully rubbed smooth, the coarse particles will do harm by increasing irritation.

For this and the previous form of conjunctivitis dry Calomel dusted into the eye with a camel's hair brush generally gives splendid results. It should be continued for a considerable time after the disappearance of all mischief, but it should be used with great caution when there is any ulceration of the cornea present. The writer uses Atropine or Cocaine Solution, and when the pain is relieved the Calomel can be applied easily.

The constitutional treatment for struma should be actively undertaken—good feeding, open-air exercise, Cod Liver Oil &c. *Absolute cleanliness* is essential. If corneal mischief results, appropriate treatment should be at once commenced. (See Cornea, Inflammation of.)

OPHTHALMIA NEONATORUM.—Hourly washing of the eye by a small stream of weak astringent lotion, allowed to fall between the open lids from a small piece of good sponge or piece of lint, will generally cut short the disease. Two nurses sit down on chairs facing each other. One takes the child and places it on its back, with the head resting upon the knees of the opposite nurse, who opens the lids with the fingers of her left hand, whilst she squeezes the lotion from the bit of sponge, allowing it to fall in a small stream upon the conjunctiva.

By far the best remedy to put into the hands of the nurse is a Solution of Perchloride of Mercury, 1 in 2,000 to be diluted with an equal quantity of hot water for use. In very mild cases Alum (8 grs. to 1 oz.) or Zinc Sulphate (2 grs. to 1 oz.) may be used.

The surgeon should see the case two or three times a week as long as the discharge is profuse, and, carefully everted the lids, cleanse them, and then swab them freely with Nitrate of Silver Solution, 10 to 50 grs. to 1 oz., finally washing off excess of silver with tap water.

Excellent results have been reported of cases treated by irrigation with a warm, weak antiseptic solution for twenty minutes three or four times daily, and the writer believes this to be an ideal treatment; but as it can only be properly carried out by trained nurses in hospital, it is not often applicable.

Cr  de advises that a drop of a Solution of the Nitrate of Silver (10 grs. to 1 oz.) should be put into the eyes of all children immediately after birth as a preventive. The disease spreads from one infant to another.

Scrupulous cleanliness is all that is necessary. It seems certain that the infection, except in some cases of face presentation, cannot occur in the vagina but afterwards. The face of the child should be washed with a different sponge and water from that used for the body. Atropine should be used along with the caustic when there is any opacity of the cornea to be noticed. When the secretion gets thin, reduce the strength of the Nitrate of Silver Solution.

PURULENT OPHTHALMIA.—Under this head are included the severe and dangerous cases caused by the inoculation of gonorrhœal matter into the adult eye, and the less frequent cases where infection is conveyed to the eyes of an adult from those of an infant affected with ophthalmia neonatorum. The treatment is in the main the same as with infants, but stronger Solutions of Silver and even the Mitigated Stick may be used. If great chemosis of the conjunctiva occurs—a dangerous symptom—it should be freely incised, and bleeding encouraged by hot applications. Iced Compresses should be applied, and the caustic application renewed again at the expiration of 24 hours. If ulceration of the cornea has already taken place, the same treatment will benefit it. The other eye, if sound, should be most carefully guarded against the possibility of inoculation by bandaging over a pad of cotton wool, or in the case of infants by sewing the lids with collodion.

CRISTOPOL'S OPHTHALMIA is best treated by frequent washing out with Solution of Boracic Acid (20 grs. to 1 oz.), or, better still, by repeated applications of Solution of Zinc Chloride (4 grs. to 1 oz.), or corrosive Sublimate ($\frac{1}{2}$ gr. to 1 oz.).

DIPHTHERITIC CONJUNCTIVITIS in the early stage must be met by vigorous constitutional treatment (see Diphtheria). After the establishment of purulent discharge in the second stage the caustic remedies mentioned under Purulent Ophthalmia may be most cautiously used, but caustics in the first or hot stage are to be condemned, then iced or hot fomentations are alone admissible.

GRANULAR OPHTHALMIA OR CONJUNCTIVITIS, OR TRACHOMA.—The predisposing causes of the affection should be removed. Thus overcrowding, want of cleanliness, smoky atmosphere, low-lying and damp habitations, all tend to produce the disease.

The discovery of a microbe, which accounts for the marked contagiousness of the affection, suggests treatment by remedies fatal to germ life. Solution of Bichloride of Mercury (1 gr. to 1 oz.) may be freely applied with a brush, and no further treatment will be required in mild acute cases save cold compresses to relieve pain, and darkened glasses to shade the light.

When purulent inflammation sets in, the indications for treatment will be mild astringent lotions used every few hours, and should the discharge continue, the treatment recommended for Purulent Ophthalmia must be employed.

In the chronic form of the disease the treatment will be to cause removal of the so-called granulations before destruction of the underlying membrane takes place. This is best done by exciting a mild inflammatory action with caustics. A large crystal of Sulphate of Copper, rubbed into a suitable form, should be applied to the affected membrane. This very old-fashioned treatment is, perhaps, the most satisfactory of all methods of dealing with the chronic affection. It is better than Nitrate

of Silver, which cannot be applied by the patient or nurse, and which is apt to cause staining, the application of the solid Sulphate being, upon the other hand, easy and free from danger. Its use should not however, be too long continued. It is a good plan to suspend its action for a time, and apply the solid mitigated caustic, followed by salt solution occasionally.

A more recent form of treatment, which gives excellent results, is the use of a 2 per cent. solution of Perchloride of Mercury in Glycerin, which is nearly painless. It should be well rubbed into the everted lids on a swab of wool.

In very obstinate cases Cocaine may be applied, and the granular membrane scarified before applying the Copper Sulphate. Failing by all these methods, surgeons have been led to produce a purulent ophthalmia by inoculating the matter from the eye of an infant suffering from ophthalmia neonatorum, or by the instillation of fresh Jecquirity Infusion* (2 per cent.). The first method is obviously objectionable.

The second, though followed generally by a violent inflammatory action which clears off the old disease and any pannus present, may leave the eye greatly improved, nevertheless, since the inflammatory action sometimes cannot be controlled and destroys deeper structures, its use should only be attempted by a specialist of experience when there is much pannus present without corneal ulceration. The newer method of squeezing out each granulation with specially designed roller forceps is highly spoken of by some. Each blade has a stirrup shaped extremity, the foot plate of the stirrup being formed by a small roller—the two rollers meeting when the blades are closed. The same remark applies to the operation of removing the granulations by Electrolysis, or by Excision or Abseission.

At the different stages of the treatment, the ointment of the Yellow Oxide of Mercury, 8 grs. to 1 oz., may with benefit be applied in most cases; the Red Oxide does better sometimes. Corrosive Sublimate Solution may be used while the Copper is suspended. This should be resumed as soon as the granulations become pale and flabby. Arnauts relies almost entirely upon the Corrosive Sublimate even in very old chronic cases, and he prefers it to all other agents, including Copper, Silver and other astringents and caustics, and his opinion is supported by that of many others. He finds the corneal vascularity so rapidly disappears, that he thinks there must be some special action of the drug upon the newly-formed vessels. Twice a week, after Cocaine, the conjunctival surface of the lids is brushed with a 1 in 100 or 1 in 120 Solution of Corrosive Sublimate, whilst a few drops of a 1 in 500 solution are to be dropped into the eye three times daily. Any little pain from these drops passes off in a few minutes.

Darier objects to the time taken up by these methods, and he therefore aims at a speedier removal of the *trachom-coccus* by the

following steps of a very radical operation which he has devised—Anæsthesia by chloroform; (2) enlargement of the palpebral fissure; (3) exposure of the entire sac by everting the lids; (4) cauterization of the conjunctiva by deep incisions parallel to the margin of the lids; (5) scraping with a Volkmann's spoon; (6) brushing in with a hard brush a solution of Corrosive Sublimate, 1 gr to 1 oz. It is hardly necessary to say that these heroic measures are not generally adopted.

CONSTIPATION.

If the physician can clearly determine the cause of the failure of the bowel to act, and if this cause has not been long in operation, its removal may often effect a complete and lasting cure. Thus in the case of a person confined within a limited space from morning till night without open-air exercise, it is surprising to see the effect which will generally follow a smart walk in the open air, especially in young subjects. Perhaps of all the causes of constipation, none is so constantly present as the state of blunted sensibility which gradually but certainly follows neglected calls to evacuate. This cause must be ever on the increase as the high pressure of modern life promises fair to remain a gradually increasing quantity. The importance of some engagement or occupation causes the patient to control the desire to relieve the bowel till a more convenient moment, and three things happen:—

1. The nerves of the rectum soon become less sensitive to the stimulus caused by the presence of the feces, and, if the disregard of the stimulus becomes a habit, the nerves fail to telegraph after a time.

2. The rectum becomes dilated and its muscular fibres weakened.

3. The feces remaining in the rectum longer than they should, undergo changes owing to absorption, and they become dry and hard, and more difficult of expulsion. In the normal state the rectum should be almost always empty. The feces passing down from the sigmoid flexure produce the sensation of a want to evacuate before the matter actually enters the rectum proper. It would appear that in the ideal state of health the bowel matter traverses the lower end of the sigmoid, and collects there and enlarges itself into the rectum with rhythmic regularity. To restore this lost rhythm should be the physician's aim.

The treatment here indicated is to impress upon the patient the necessity of going to the closet at a certain fixed hour every day, and by patience and artificial means to get the bowel into the habit of emptying itself daily. The experience of nearly every one points to the time immediately after breakfast as being the most suitable. It is a common error for the physician to direct the patient to go to the closet and strain or bear down from day to day till his efforts are rewarded with a painless evacuation. There

are various grave reasons why this should not be encouraged to undue extent, hæmorrhoids, prolapsus, and fissures are constant the result.

Owing to the formation of the ordinary water-closet seat, an attempt at bearing down drives the pelvis tighter into the circular aperture of the seat, the bevelled sides of the opening also act as an inclined plane and the result is that the skin and mucous membrane around the anus become stretched to such an extent that cracks and fissures are formed, and the writer has satisfied himself that the brittle and unhealthy state of the integument observed in this region is owing to this stretching, which is of the starting point of prurigo and eczematous distress.

The modern fashion, originating in the sense of comfort & ease, should be corrected by the substitution of an aperture of different shape, and very much larger.

Evacuation should be artificially assisted by enemata or other means for several mornings, until the bowel begins to show signs of responding at the fixed hour. A cold water enema of about tumblerful, injected whilst in the standing posture, so as only to reach the lower part of the rectum, is the best method of starting the intestinal tube to contract. Glycerin, in doses of a spoonful or less, injected with a syringe made for the purpose, acts powerfully by stimulating the membrane, but its present popular professional reputation as a remedy for constipation rests altogether upon a misconception of its advantages. By its powerful stimulation of the coats of the rectum (partly through hygroscopic property), it ultimately blunts the sensibility of rectal nerve filaments to smaller stimuli, and if solely relied on the end will be worse than the beginning.

Its value seems to be clearly like that of most purgative remedies; it is of use in tiding over constipation till other means have time to act. The enema may be substituted by a Glycerin suppository which acts equally well.

These suppositories afford, perhaps, the most convenient known methods of overcoming temporary constipation within five minutes, and sometimes immediately, a copious painless motion may be experienced after their introduction. In affections like typhus and typhoid fever their action is nothing whatever to be desired. In hæmorrhoidal cases, and in cases of anal fissure, however, their use sometimes bring on a very acute attack of pain and tenesmus. They have generally obtained all the advantages claimed for Glycerin by inserting within the internal sphincter a piece of ordinary wood shaped with a knife to suit the purpose and this has been done in cases of anal ulcer without any ill effects whatever, except momentary smarting. Both these plans, Glycerin suppositories do splendidly with children.

Should there be already accumulations of faeces in the rectum and colon for some time, they must be removed, and

purpose ordinary purgation by the mouth is not to be thought of. A tepid water enema should be given when the patient is lying upon the left side, with the view of getting the fluid beyond the accumulation, two or three quarts, if slowly thrown up, are safe, and generally effectual.

Caster or Olive Oil may be administered along with the water with great advantage. It is useless to pour the oil into the water, where it floats, and is not injected into the bowel till the very last. The nurse should lift the end of the enema pipe (lying in the water), and put it into a cupful of the oil, and continue the operation before without removal of the other end from the rectum. After pumping up 3 or 4 ounces or more in this way the end of the pipe is taken out of the oil and dropped into the warm water again, and the pumping gently continued till the patient cannot tolerate the introduction of any more fluid, when the motion will occur. To remove lodgments from the colon several enemata may be required, and should the mass be above the reach of the finger, weeks may be spent in pumping it out, though this is decidedly optional. Should the mass be low down it may be broken up with the handle of a spoon or scoop, and removed piecemeal. Injections of Oils, Gruel, White of Eggs, Linseed Infusion, and various other emollients are used. Brewer's Yeast, when injected, breaks up and causes the rapid disintegration of the impaction, and as it is harmless it should have a trial.

Having then got the intestinal tract cleared in a case of chronic constipation, the physician's next attempt is to assist the patient in having a daily evacuation of the bowels, or if an evacuation every second day has been the patient's life-long habit when in health, the effort should be to restore this habit, and not to attempt to improve upon nature.

Much can be done, as already suggested, by urging the patient to take a brisk morning open-air walk or ride if his habits have been sedentary. Unfortunately, in many instances, the class of patients to whom this would be valuable have little opportunity for walking, and the haste to reach their offices in the city only permits them to indulge in their usual omnibus or railway trip. To such, a half-hour's cycle ride will be followed by splendid results.

Much can be done by diet. It is generally the small eater or spare liver who is the victim of chronic constipation, and often if each a one, from any cause, begins to eat almost any sort of food in larger quantity than is necessary for the maintenance of health, the constipation disappears. In prescribing a dietary, foods which leave a bulky residue should have the preference. Brown bread, whole-meal bread, or any bran bread-stuffs are of great use. Oaten meal made into porridge, and taken at bed-time or before the ordinary breakfast, is the remedy which keeps many folk in health for years.

Vegetables and fruit should be taken freely, and an orange or apple eaten early in the morning or orange marmalade at break-

fast answers well in some cases. There is nothing better than a good supper of boiled Spanish Onion, and the writer has treated obstinate cases of constipation by this means alone with very satisfactory results.

To patients who can bear a good-sized spoonful of pure Olive (Salad) Oil every morning after breakfast, it is a valuable laxative and food. The writer has noticed that it is not well borne by the plethoric, or by lean folk with dark skins. The pale, washy-looking, blue-eyed, sedentary, thin subject gets much benefit from it or from Cod Liver Oil when taken once a day in one large dose.

Figs and Prunes are serviceable, but even children grow weary of their lusciousness. Stewed prunes do well for a short time.

It is often a good thing to advise the patient to become a vegetarian for a time, and if he takes to the practice and makes a "fad" of it, his constipation, as a rule, disappears.

A diet consisting largely of boiled eggs is sometimes the cause of the most obstinate constipation and accumulation of feces.

The Matlock system of wearing a cold water compress over the abdomen in the morning is of use, and Massage or kneading of the abdominal muscles over the entire course of the large intestine may be tried in very sluggish subjects, or even a smart friction over the abdominal walls with a coarse, warm towel for five minutes on rising, followed by a large drink of cold water and a smart cold shower or plunge bath, may do more good than medicines. Brunton recommends rolling a cannon ball (7 lbs.) over the abdominal walls, following the direction of the colon.

Electricity—a weak continuous current, with one pole on the spine and a large wash leather or sponge electrode moved about over the lumbar and hypochondriac regions, or a smart interrupted current may be used with advantage in the same way.

By a careful attention to the above methods, the physician will find that most of the cases of chronic constipation will be successfully combated without having to resort to the long list of purgatives in daily use. As a rule, active purgation should not be permitted, and, in many of the cases seeking relief, continual purgation indulged in for fancied ills will be found to be the cause of the constipation.

To increase the muscular and nervous tone of the bowel, and, at the same time, to increase the intestinal secretion so as to bring the motions to a healthy state of consistence, should be the objects aimed at in the treatment of chronic constipation with drugs.

Of the selection of purgatives there seems to be practically no end, and only a brief reference to the most valuable can be attempted.

Cascara Sagrada comes first in value, and when all the dietetic and previously-mentioned plans have failed, the patient should be placed upon small doses of the liquid extract. It may be given in various ways. One moderate dose in the evening or before bedtime, the treatment not to be commenced till the existing consti-

pation is for the moment corrected by some brisk purgative, is the most successful plan. Beginning with an evening dose of 30 minims in a few days the physician will obtain some idea of the dose suitable to the individual case and the initial quantity is increased or diminished accordingly.

The object to be clearly aimed at is to avoid purgation and to give the remedy in such a dose as will secure one soft, natural motion every morning. The amount and the interval necessary to produce this result varies widely in different individuals, and in the same individuals at different seasons of the year.

There is the greatest difficulty in getting patients to graduate the dose themselves, and after a few weeks they stop the cascara altogether, through carelessness, or a belief that they are cured of the constipation, and when the bowels return to their old habit, a large dose of cascara is taken as a purge. This is certain to be followed by more obstinate constipation, and thus the remedy is set down as useless. The physician should insist upon a two months' course at the very beginning of the treatment.

Another method is to give the cascara three times a day, after meals, in a dose equivalent to about one-third of the nightly dose. Thus, 10 minims may be given immediately after breakfast, luncheon and dinner.

No matter which plan be adopted, after a few weeks the dose should be gradually diminished, still, however, taking enough to produce the healthy natural morning motion, as if no purgative had been administered. At the end of a period, varying much in different cases, the remedy may be occasionally suspended for one day, and finally, in a few months in some cases, it may be permanently stopped.

The cascara may be given alone, or combined with some of the remedies about to be mentioned.

R. *Extracti Cascaræ Sagradæ Liquidi* ℥ii.
 Tincturæ Nucis Vomicae ℥iii.
 Tincturæ Belladonnae ℥iii.
 Glycerini q.s. ad ℥iv. misce.

Fiat mistura, cujus capiat cochlearium minimum omni vespere et mane ad quatuor vicem, deinde omni vespere.

Sometimes the cascara is given before meals, and capsules containing any requisite dose may be had easily from any chemist, but, though elegant and effective, the dose cannot be easily regulated when the capsular form is used. The pilular extract may be given, but the fluid is more certain and uniform in its action.

Aloes comes next to cascara in value in the treatment of chronic constipation, and it is possible in some years hence, that it may regain its old position at the head of the list. Like its newer

rival, if judiciously administered, the dose need not be increased, whilst, in many cases, it may be diminished, and finally withdrawn as the constipated habit becomes cured. It is best given in combination with other laxatives or cathartics as it is slow in its action, and, when given in small doses, does not soften the motions much, but stimulates the peristaltic movement. It is a tonic, and very markedly increases the quantity of the biliary secretion. It must never be forgotten that a moderate dose of aloes requires for its action 12 to 15 hours or more, and hence the importance of administering it at a time when the normal morning hour for evacuation should not be interfered with.

Its action in chronic constipation is very materially increased by combining with it Sulphate of Iron, and Dr. Spender's famous pill is a splendid combination.

R. *Extracti Aloes Aquosi* gr. i.
Ferræ Sulphatis gr. ii. misce.

Fiat pilula. Mille tales L.

Signa.—"Take one 3 times a day for 7 days, then one twice a day for a fortnight, then one every night."

If the constipation be associated with amenorrhœa, the combination of aloes with iron is the best possible treatment.

Much conflicting opinion has been given about aloes in the treatment of constipation when associated with hæmorrhoids, and the matter may be safely disposed of in this way—Large purgative doses often seriously aggravate hæmorrhoids when present, whilst small laxative doses generally relieve and produce decided curative effects, and good results have been obtained by treating hæmorrhoids exclusively by small doses (1 grain) of the extract of aloes given night and morning.

The compound decoction of aloes is a most unsatisfactory laxative in chronic constipation, and though of the greatest value in other intestinal disorders, it is not to be depended upon, as it is almost impossible to regulate the dose so as to produce uniform results, and frequently it causes constipation.

The best results with aloes are obtained by the old-fashioned dinner pills, in which a small dose of aloes is combined with Iron, Ipecacuanha, Capsicum, Nux Vomica, Myrrh, and Belladonna or Hyosciamus, and given immediately before or after dinner.

The following is an excellent combination :—

R. *Extracti Aloes Socotrina* gr. ss.
Extracti Nucis Vomica gr. ss.
Pulveris Ipecacuanhae gr. ss.
Pulveris Capsici gr. i. misce.

Fiat pilula. Mille tales xxiv. Sumat unam omn. die ante prandium.

Sir L. Brunton recommends—*Pil. Rhei Co.* and *Pil. Colocynth.*
Co. ʒ gr i., *Ext. Hyoscy.* gr ss.

So A. Clarke used this formula:—*Ext. Nuc. Vom.*, *Ferr. Sulph.*,
Pale Myrrhe., *Pale Saponis*, *Alum ana.* ʒ gr. The quantity of
 aloes is to be increased or diminished according to the effect
 produced upon the bowels.

Owing to the length of time aloes takes in acting, it is a mistake
 to give small doses at bed-hour, because they may, as already
 mentioned, produce no effect upon the morning evacuation.

In usseau found the best results in the treatment of chronic
 constipation to follow the administration of

Belladonna. The green extract in doses of ʒ to ʒ gr. given at
 bedtime alone or with as much Extract of *Nux Vomica*, may be
 tried. *Belladonna* may be given with any laxative in a dinner
 pill, when it will not only strengthen the muscular contractions of
 the bowels, but will to some extent prevent griping. The tincture,
 in small doses, is a very excellent treatment for the constipation of
 infants and children.

Strichnine or *Nux Vomica* in constipation is of the greatest
 value as an adjunct to other drugs and occasionally alone it meets
 every requirement. The following formula combines the most
 valuable of agents:—

- R. *Ext. Nuc. Vom.* gr. ss.
Alum et Ferr. Sulph. Ext. ana. gr. iss.
Ext. Belladonna gr. ʒ.
Ext. Canaris Sagrada gr. i. *mixc.*

By modifying the dose of the different ingredients in this pill
 nearly every case of chronic constipation can be treated with
 success.

Colocynth. in small doses is good and the best preparation is
 the *Pilule*, *pharmacopœia* *medica* in doses of ʒ to ʒ gr. *medica*
 direct or a larger dose at bedtime. The compound extract may
 be given at a dinner pill in doses of ʒ gr. *medica*.

- R. *Phiale Colocynthidis Co.* gr. xiv.
Ferr. Arsenatus gr. i.
Extract. Belladonna gr. viii. *mixc.*

et divide in pilulas, regias. Siga.— One after dinner.

In a few words the compound is to be dissolved by sea-salt
 and in a few words more it may be stated as follows, and
 Extract of *Nux Vomica* is to be used.

Although *Strichnine* and *Nux Vomica* are the most powerful
 agents in the treatment of constipation, and a good preparation
 is the *pharmacopœia* *medica* in doses of ʒ to ʒ gr. *medica*

curative, and the reason why so many old folk stick to it is because once they get into the way of using it they cannot well do without it.

Podophyllin is much more valuable in the treatment of acute constipation where a satisfactory brisk purge is required, nevertheless it is useful in the chronic constipation of bilious subjects. It may be given in combination with Belladonna.

R. *Tinctura Podophylli* *ʒi.*
 Tinctura Belladonna *ʒiv.*
 Tinctura Zingiberis *ʒvi. misce.*

Fiat mistura. Sumat gulas xx. omni nocte ex paululo sacchari.

Nothnagel recommends the following formula as a laxative in chronic sluggishness of the bowel: -Podophylli Resinæ, gr. ixxx.; Ext. Aloes Aq., gr. xlv.; Ext. Rhei, gr. xlv.; Ext. Taraxaci, q. s.; misce. Divide in pilulas xl. Signa—"One, two, or three at bed-time."

Euonymin in pilular form acts much in the same way.

Castor Oil in small doses has been given for long periods with advantage. Thus in the chronic constipation of pregnancy it is the best remedy in morning doses not exceeding one drachm, and may be taken with impunity all through.

Many recent reports testify to the value of Creosote in full doses (5 min. ter die).

Saline Purgative Waters, as Friedrichshall, Carlsbad, Hunyadi Janos, Pullna &c., are very valuable as occasional adjuncts to the aloes or cascara treatment, and they are invaluable in the management of occasional constipation, but unless the above rational lines of treatment by small laxative doses fail, their constant use is not likely to be followed by cure of the ailment if of long standing.

Senna, Jalap, Scammony, Gamboge, Croton Oil, Epsom Salt, and Mercurials are not available for the treatment of chronic, though valuable for the relief of acute or occasional constipation.

Tamar Indien is an excellent remedy, and when administered with care to regulate the dose, is a very successful method of treating chronic constipation in patients whose feeble health or chronic ailments confine them to the house for the greater part of the year. It produces very large, almost solid motions, and its action is not followed by any tendency to constipation, and the dose can be easily diminished by the patient.

Sulphur is a good drug for the relief of chronic constipation, and may be given in the morning before breakfast mixed with a spoonful of Orange Marmalade, and the Compound Powder of Liquorice is a palatable laxative and one of the best routine drugs for occasional constipation in childhood. Two or three Compound Sulphur Lozenges may be given at bed-time.

For the constipation of children, many of the previously mentioned drugs are not suitable. In infants the cause of the constipation when it exists is generally bad feeding, and it generally disappears when this error is corrected. The best drug for infants and young children is Castor Oil, and a daily very small dose—half a tea-spoonful—generally removes the condition.

Glycerin suppositories, containing 90 per cent. pure glycerin, when inserted into the rectum act with great promptness and thoroughness. Ordinary injection of 30 minims of glycerin acts satisfactorily and may be used daily. This remedy is not objectionable in the case of very young children as the writer thinks that the act of evacuation in them is more dependent upon the state of the great intestine higher up than the rectum and the fact of accustoming the rectum to a smart stimulus from day to day does not appear to blunt its sensibility so as to interfere with the act of defecation after the injections are stopped, as appears to be the result in adults.

Soap suppositories, made by cutting a small fragment of hard soap into conoidal form, and inserting it into the rectum, act also very well.

Compound Liqueur Powder, or 2-5 gr. doses of Sulphur, may be given for considerable periods with advantage.

Manna is a safe laxative for very young children, and may be given freely for a long time till the constipated habit disappears.

Injections of tepid water, 5 to 10 oz., may be given occasionally to young children, and 3 to 6 oz. in cases of congenital constipation. It is needless to say that in these cases a very careful examination of the anus and rectum is essential when the bowels remain obstinate for any length of time in infants or very young children.

To acute attacks of constipation occurring in a person otherwise healthy, and where there is no abdominal obstruction, it will be seen that the foregoing remarks do not apply and the treatment for such attacks is a smart purge. Any of the remedies already mentioned may be given in large doses. The old-fashioned method is the best, of giving at night a combination of cathartics, whose slow action upon different parts of the intestinal tube is "overtaken" by a smart dose of a Saline early in the morning. Thus, 5 grs. *Phil. Hydrag.* and 5 grs. *Phil. Col. Co.* taken at bed-time, and 2 oz. Black Draught early in the morning, is a very efficient purge for robust men.

It must not be forgotten that diarrhoea is sometimes, especially in elderly people, caused by a mass of scybala lodged in the colon, and the proper treatment in such a case is to give a purge and commence with large enemata of tepid water, given whilst the patient is placed upon his left side. Should the mass be high up in the colon, the patient should be placed upon his knees and elbows, and afterwards turned over upon his right side, so as to assist the water to gravitate towards the ileo-caecal valve.

CONVULSIONS.

A correct idea of the treatment of convulsions can only be obtained from a knowledge of the different conditions of which the convulsions may be the only symptom. Thus the presence of a mass of round worms in the intestinal canal of a child will call for Santonin and a purgative. (See *Ascaris*.) The convulsions arising in a patient suffering from advanced renal affection will demand the active treatment necessary for uræmic poisoning. (See *Bright's Disease*.) Epileptic convulsions will be best prevented by Bromides, &c. (See *Epilepsy*.) In the same way the reader will find under *Hysteria*, *Tetanus*, *Poisoning by Strychnine*, *Teething*, *Apoplexy*, *Alcoholism*, *Puerperal Convulsions*, &c., the appropriate remedies mentioned by which the convulsions may be prevented or modified or rendered less frequent.

If called to see a patient labouring under an attack of convulsions (without any apparent cause demanding immediate attention, such as pregnancy or uræmia), the physician will have considerable difficulty in preventing himself from acting under the impulse "that he must do something." The position of "masterly inactivity" is the safest as regards drugs in a situation of this sort, where at the moment little can be determined about the causation or pathology of the symptoms. The patient should be placed in bed upon his back with his head and shoulders slightly raised, and all constrictions about the neck, thorax, or abdomen removed. If the tongue be protruded, and in danger of being wounded by the closure of the teeth, a lemonade cork may be inserted between the upper and lower molar teeth on one side. Unless the convulsive movements be severe and liable to cause contusions of the limbs or scalp, restraint should not be resorted to. In a series of rapidly succeeding attacks the vapour of Nitrite of Amyl may be judiciously employed. Chloroform or Ether may be administered upon a sponge, or Chloral Hydrate may be given by the rectum. Heroic measures, like blood-letting, are unjustifiable, except in puerperal cases.

Infantile Convulsions.—The routine plan of scarifying the gums in every case of convulsions occurring in young children should be strongly condemned. The tough cicatrix, forming over the incisions afterwards, is generally the source of serious future trouble. The writer has seen the leathery gums of infants who had been subjected to wholesale scarifications months previously for supposed delayed dentition, when the cause of the convulsions was probably a mass of curd in the intestines, the result of indigestible cow's milk. Sometimes, when the tooth should be above the gum, these old, dense cicatrices so hold it down, that the only course is to snip a piece out of the cicatricial tissue with scissors or a knife.

Called to a case of infantile convulsions between the fifth and thirtieth month, the writer, after thoroughly disinfecting his index finger, passes it into the infant's mouth and feels for any

prominences over the line of the teeth, and if any tooth feels to be very near the surface, he scrapes through the tissue of the gum till the cusp of the tooth is felt grating against the edge of the finger nail. The little operation is almost painless if the finger nail is sharp, and healing over of the lacerated wound never occurs.

Simon gives 15 grs. Chloral to a child 12 months old. This drug may be given hypodermically in doses of 3 grs. to a child 1 year old, or it may be given by the rectum after washing out the bowel.

Bromides are the remedy for convulsions of this class, and may be safely administered in all cases where there is reason to suspect repetition of the attack in children or adults. A good formula for an infant of one year old is—

Ammonii Bromidi gr. xlv.
Tr. Belladonnae ʒj.
Chloral Hydratis gr. xxxv.
Syrupi Aurantii Floris ʒss.
Aqua Chloroformi ad ʒiii. misc.
Fiat mistura, Sumat ʒi. omni hora.

A warm bath is often efficacious in arresting the fit in an infant or young child; a Mustard and Wheaten Flour poultice (equal parts) may be placed over the nape of the neck. Cold water in a continuous stream directed against the fontanelle has been strongly recommended, and compression of the carotids may be tried. It is always advisable to clear out the bowels with a smart purge as soon as the patient can swallow.

For the convulsions coming on during the progress of brain diseases and cerebral tumours, large doses of the Bromides, combined with Iodide of Potassium, are indicated.

CORNEA, Inflammation of.

For inflammation of the cornea following extensive conjunctivitis, and ending in suppuration or ulceration, the indications are to relieve pain by the instillation of Atropine, or if there be much tension or danger of perforation, Eserine should be employed, especially if the ulcer be marginal. To secure absolute rest the eye should be carefully bandaged, or a large shade placed over both eyes. In the inflammatory stages, with much photophobia and pain, astringent and stimulating applications must be avoided. Warm fomentations and Belladonna Extract, rubbed ʒ with Glycerin, may be smeared over the brow and outside of the lids.

Should there be much secretion bandages should be avoided, and the constant use of a weak antiseptic antiseptic lotion must be kept up. Potash. Acid is the safest and most efficacious, ʒi. dr. to ʒi. oz. Perchloride of Mercury ʒi. gr. to ʒi. oz., may be used.

Where the photophobia is intense a free division of the outer canthus may be made, and counter-irritation or leeches to the brow often afford considerable relief.

When the acute stage is over, much benefit will be obtained by stimulating treatment. This may be carried out before pain subsides if Atropine be constantly used. The best application is the yellow Oxide of Mercury Ointment, but it is too often used of a strength that aggravates the affection. 8 grs. to 1 oz. Vaseline is generally strong enough for all purposes, and sometimes half this strength will be found to answer better. A minute portion of the ointment may be inserted inside the lids twice a day, but the effect must be watched carefully, and it should be stopped at once if signs of irritation reappear.

Calomel, dusted inside the lids once daily, often acts with great rapidity, and causes the ulcers to take up new action and induces rapid granulation. Seldom will Nitrate of Silver be required. In large pustules or sluggish ulcers, a mixture of Cocaine (8 per cent.) with Atropine Solution relieves pain and tension, and Mitigated Caustic may be lightly applied to the ulcerated spot with very marked benefit. Better still, after the instillation of Cocaine or the use of a Cocaine disc, a little of the Nitrate may be applied in solution (10 grs. to 1 oz.) with a fine camel's hair brush, confining the application strictly to the ulcerated spot. This method may even be employed for deep ulcerations of the cornea if perforation do not threaten, and if there be no iritis. Absolute alcohol is sometimes used in a similar way to disinfect the floor of the ulcer. Eserine may be freely used in such cases.

In very chronic cases, a seton above the temple or behind the ear, or blisters in the same locality, prove useful. When the ulceration is caused by the presence of granular lids, this condition must be met by proper treatment. (See Conjunctivitis.) The thermo-cautery, or a probe heated in a spirit flame, should be used where the edges of the ulcer are extending.

Ford resorts to peritomy in troublesome, ulcerative, strumous, or suppurative keratitis, upon the principle that as the cornea receives its blood supply from the conjunctiva, the local depletion, consequent upon a division of its vessels and of the loops which surround its circumference, tends to promote a healthy reaction and an absorption of stagnant cellular elements.

Walker has introduced a new operation under the name of Perikerotomy, or "cutting round the cornea" in these cases; he makes a series of short incisions at the base of the cornea.

Shaw points out the necessity, where the ulcer is threatening, of anticipating perforation as the best means of preventing the aqueous humour escaping with a gush and carrying the iris with it. He perforates the floor of the ulcer with a fine knife.

Internal treatment is of the greatest value, and constitutional measures must be employed from the beginning. Thus, in the phlyctenular form, as in strumous ophthalmia, of which it is

generally a part, the treatment directed under Conjunctivitis must be carried out, and an early change of air and scene is often followed by marked benefit. Special attention should be paid to the feeding of the patient, regular meals at regular hours being insisted on even for the youngest, and all forms of light refreshment between them absolutely prohibited.

When Atropine, Everine, and Cocaine fail to give satisfactory relief to pain the remedies found useful in neuralgia of the affected nerve may be employed. 5 grain doses of Butyl Chloral every two hours for 4 doses may be given. 30 grs. of Chloride of Ammonium, or 5 minims of the Gelsemium Tincture every two hours may be administered. In severe cases, especially in elderly patients with serpiginous ulceration, the free administration of stimulants with Sal Volatile in Decoction of Cinchona (40 minims an oz.) must be attended to.

If the inflammatory action extends and hypopyon form—i.e., pus appearing in the lowest part of the anterior chamber—if its absorption does not follow upon the continuance of the above treatment, a free incision or an iridectomy must be made; if only an incision be decided upon, it must be re-opened daily till the secretion of pus ceases.

Chronic or interstitial KERATITIS almost always depends upon inherited syphilis, and in addition to the remedies for the relief of pain and photophobia as mentioned above, the internal administration of Mercury must be pushed short of producing salivation. After acute symptoms subside, the Yellow Oxide of Mercury Ointment (1 gr. to 1 drachm) should be daily applied.

Recently Zeigler has drawn attention to the frequency with which corneal ulcer is caused by nasal disease, and the importance of treating this before any permanent improvement in the eye can be expected. The nasal chambers should be thoroughly cleansed, and a swab of lint soaked with Friar's Balsam should be applied to the nasal membrane far back and over the inferior turbinated bone. If the patient is a child, and nasal obstruction exists, adenoids will probably be found, and if found, they should be removed.

CORNS AND CALLOSITIES.

By the removal of the cause i.e., friction, or intermittent pressure produced by tightly-fitting boots, the corn will soon disappear. The presence of corns, in many cases, is owing to the boots being too large: the friction caused by the skin of the foot rubbing against the leather in walking is enough to produce painful corns. Children frequently have their boots made too long, in order to allow for the growth of the foot during the wear of the boot. The result is that they get into the habit of strongly flexing their toes in walking, to prevent the slipping up and down of the foot inside the boot. The result is, corns appear on the upper surface of the

phalangeal joints, and deformities of various kinds result which last during life.

The first indication, in the treatment of these conditions, is to obtain properly fitting boots. (See Bunion.)

The corn should be pared with a sharp knife and if skilfully done, it can be entirely removed at one operation, but this requires skill and much practice.

After the removal of the thickened epithelium, if the corn cannot be cut entirely out, a little Glacial Acetic Acid may be applied with a bit of wood (the end of a match), and, after the superficial film peels off, the application can be renewed till the diseased cuticle disappears.

The favourite remedy is Salicylic Acid. It is the basis of nearly all the corn cures in the market. It appears to possess the strange property of only dissolving or acting upon the diseased epithelium, having no effect upon healthy tissue.

The usual formula is—

R. *Acidi Salicylici* ℥i.
 Extracti Cannabis Ind. gr. x.
 Collodii Flexilis ℥vj.
 Ætheris Sulphurici ℥ii. misce

Fiat solutio. *Signa* :—To be daily painted over the corn.

Soft corns may be best treated by the separation of the opposing surfaces with felt or Amadou Plaster, with a circular hole cut in the centre. This hole may be filled with dry Salicylic Acid, and afterwards the above solvent may be applied.

Rosen treats corns, warts, and callosities so :—The growth or patch having been well moistened with an antiseptic solution, is thickly covered with Salicylic Acid. Upon the top of this is placed several layers of moistened Boracic lint, and over all a piece of gutta-percha tissue and a bandage. At the end of five days, when the dressing is removed, the thickened epidermis easily peels from the subjacent structures.

Unna treats plantar corns by painting a broad ring of Glycerin Jelly round them with a stiff brush. When the jelly has firmly set, the interior of the ring is filled with a circular piece of strongest Salicylic Plaster (Salicylic Acid, 40. Creosote, 40), and the whole covered up with two layers of glycerin jelly, and when dry a small pad of cotton wool. This dressing will last for a week, and may be renewed till the horny layer of the epidermis is entirely removed.

Chromic Acid, Iodine, Moxas, and Caustics of various kinds have been employed, but Salicylic Acid is much better.

OORYZA—See Catarrh and Bronchitis.

COUGH.

Under Bronchitis the treatment of cough is discussed, but the physician will meet with many cases where a persistent dry cough or bark is the only symptom present, and where the most careful examination fails to discover any abnormal physical sign in the lungs or air passages.

To successfully treat such cases it is obvious that the cause of the cough must, if possible, be ascertained. If there be any reason to suspect from the history of the case, or by a careful reasoning from all the available data, that there is any latent pulmonary mischief present, the ordinary sedative remedies before mentioned may be employed. Thus the hacking, short, dry cough of early phthisis may be traced to its cause, should there be a sub-febrile temperature, marked loss in body weight, and a bad family history with untavourable surroundings, and the proper treatment will be easily indicated, though no expectoration or physical signs be present. In dry catarrh of the bronchial tubes of large size, though the writer has seen many such cases where no real or physical sign existed, nevertheless the presence of some small quantity of tenacious or inspissated mucus or muco-purulent secretion at some time or other will be found to clear up the case. The treatment in such a case must include more than mere sedatives or palliatives. The dry bronchial surface must be stimulated so as to cause the pouring out of a secretion of liquid consistence, after which often the cough practically ceases.

The injurious administration of sedatives and narcotics in a haphazard way in bronchitis has already been mentioned, but the physician must not err in the other extreme, especially as incessant, violent, or spasmodic attacks of cough without any expectoration may in time lead to serious pulmonary trouble.

Excluding, then, all cases of cough having their origin in bronchitis or laryngeal inflammation or diseases, it may be found that the throat is the seat of the irritation. Acute or chronic granular conditions of the pharyngeal mucous membrane may produce incessant coughing. Elongated uvula, enlarged tonsils, polypi, and other growths at the back of the posterior nares may call for appropriate local treatment.

For the treatment of the reflex cough accompanying catarrhal sore throat, there is no remedy so effectual as a spray of the following, which may also be used as a gargle :—

R. *Acidi Carbolici* ℥i.
 Cocaine Hydrochloratis gr. vi
 Glycerini Acidi Borici ℥ss.
 Aquæ Rosæ ad ℥xii. misce.

The inflamed membrane can also be treated by Chlorate of Potash Nitrate of Silver Alum, Tannin, or local sedatives as inhalations of Camom, Friar's Balsam, or Menthol Spray.

Far cough unquestionably is to be met with, and unless the diagnosis be correctly made there is little probability of the cough being relieved by drugs. A careful examination will reveal some irritation or foreign body in the meatus. In the case of children, peas, beads, &c., may be found, and in adults, plugs of dried wax. The wax is more likely to give rise to cough if partially loose in the passage, and sometimes the movements of the jaw in eating or speaking may so disturb the mass that cough results at these times. The removal of the foreign body by syringing is generally followed by instant relief.

In infants the advent of each tooth is sometimes heralded by a smart spasmodic cough, which stops when the crown is through the gum, and in older patients the removal of a painful or carious stump has been sometimes followed by the cessation of a cough that has been a source of anxiety for a long time before.

Liver diseases (abscess and calculi) have been the cause of cough, and in one case known to the writer a bilious attack, resulting from indiscretion in eating, always brought on a severe, spasmodic, barking cough, relieved or removed by a smart purge.

The stomach cough has been long recognised, and yields to remedies which cause evacuation of the gastric contents, or to sedatives like Bismuth, Codeine, or Hydrocyanic Acid.

Gout may be ushered in by a severe cough, which is relieved when the paroxysm localises itself, and the presence of foreign irritants in the intestinal canal—as round worms, fruit seeds, &c.—may cause cough in children, which yields to a smart purge.

Hysterical cough should be treated by antispasmodics like *Asafetida* and *Valerian*.

Severe spasmodic or reflex cough, arising from almost any cause, is always benefited by large doses of the Bromides, especially by the Bromide of Ammonium. Chloroform, in moderate doses (5 minims), is a powerful sedative in most cases, and Chloral Hydrate, in small oft-repeated doses, will allay cough when the cause cannot be removed. *Gelsemium*, *Grindelia*, *Conium*, and *Sanguinaria* may be used like *Morphia* and *Codeine*, to lessen the sensibility of the respiratory centre. *Guaiacol*, in full doses, 5 to 10 mins., has been much used in spasmodic cough not depending upon pulmonary phthisis; and *Hydrastis* has recently been advocated by several. *Phenacetin* and the new analgesics are valuable where *Morphia* is contra-indicated, and they can be combined with Bromides. *Heroin* ($\frac{1}{4}$ gr.) is recently extolled.

Sir A. Clarke believed the *barking cough of puberty* occurs in over-fed or too-often-fed children. He insisted upon a simple but liberal dietary of three or at most four meals a day, active out-door exercise, and early hours. Locally, he used Glycerin of Borax with Oxychlorate of Bismuth and *Morphia*; or the same mixture with 10 per cent. of Cocaine, instead of the *Morphia*, brushed over the whole interior of the throat after each meal and

at bed-time. Internally, he used the Syrup of Bromide of Iron and Quinine, with small doses of Arsenic. When this failed he gave a pill containing Reduced Iron, Valerianate of Zinc, Belladonna, and Nux Vomica, pushed till the physiological effects of the Belladonna showed themselves.

CRAMP.

The very painful tonic spasm which commonly affects the muscles of the calf of the leg often calls for treatment. Smart friction may be employed over the contracted muscle, and, by a voluntary effort, the opposing muscles may be thrown into firm and prolonged action, which soon relieves the spasm. By tying an elastic band like Esmarch's, tightly round the thigh, sometimes the cramp yields at once. If it occurs when in the recumbent position immediate relief may often be obtained by assuming the spring posture. Often the condition is the result of over fatigue of the affected muscles, which must be met by rest, and where deficient elimination of effete products is the cause, agents like Salicylates and Massage are beneficial.

For the craft-spasms or palsies see under Writer's Cramp, &c.

CRETINISM.

After the discovery that marked improvement followed the use of thyroid feeding in myxedema, it soon was anticipated that this treatment would tell upon the same disease appearing in childhood—viz., sporadic cretinism.

Grafting and injections have now given way to direct feeding by the mouth and this method has been proved to be successful in many hundreds of cases of cretinoid idiocy. Many of the results tax the credulity and faith of those who read them, but the numerous well-executed photographs accompanying the clinical reports show that the efficacy of the treatment has not been overstated. There is some difficulty in determining the correct dose, but any case may be commenced with a tabloid containing 2 grs. of dried Thyroid twice a day, and if much increase of pulse rate, or if the loss of weight becomes very marked, the dose may be lessened. The Thyroid may be increased in any case till the low temperature, so often noticed, comes up to the normal and keeps there.

Generally speaking, the remedy may be safely given under close supervision in full doses till the body weight falls to what should be the normal for the child's height; then it begins to rise again, when the dose may be reduced to what will keep the patient in a condition of health—this will be found to be about one 5 gr. dose of dried Thyroid twice a week.

Even in cretins of 20 years of age improvement may be soon visible, and the dwarf stature, which had remained stationary for many years, begins to alter, so that after 12 months an increase in height of 6 or more inches may be noted. The dry skin

desquamates, and the new skin retains its moistness, and in a few months the features become altered; their thick coarse texture change, and they become sharp, and the expression lively and pleasant. The unimprovement in the mental condition is generally surprising as the cretin gradually rises to a higher moral, intellectual, and physical level.

Upon the suspension of the Thyroid feeding the patient slowly retrogrades, and it is probable that the gland must be administered all through life.

CROUP.

Any remarks about the treatment of croup must be valueless, unless it be made clear which of the conditions embraced under this misleading name is prominently before the mind of the writer when discussing the question. In the first place, the affection known as *Laryngismus Stridulus*, and unfortunately wrongly called False Croup—a purely nervous disease, not associated with any laryngeal inflammation—is not referred to here. Its treatment will be mentioned under its own name. Acute Laryngitis, which at the bed-side can be differentiated from the varieties of croup, is also left out of consideration for the present.

There remain subject to further explanation two distinct affections at least—known under the common names of False Croup and True Croup. About the first (or False Croup) there should be little difficulty. It is spoken of as False Croup, Spurious Croup, Spasmodic Croup, Inflammatory Croup, Stridulus Laryngitis, Spasmodic Laryngitis. (Some of these names are unfortunately applied to *Laryngismus*.) In the great majority of cases, where the services of the physician are urgently demanded for the relief of croup, it will be the spurious or spasmodic variety which he will have to deal with.

The attack generally occurs *suddenly* and at night, the child waking with a hoarse, hard, clanging cough. His voice and cry may be hoarse but not whispering. There is alarming dyspnoea from the beginning, and each inspiration is attended by a loud creaking or crowing sound. The attack, if left alone, may probably pass off in a few hours. The child falls asleep, and awakes nearly well, though the attack probably will return again upon subsequent nights.

The physician perceives that, called by whatever name, he has got to deal with a mild *laryngitis*, probably of catarrhal origin, accompanied by spasm of the laryngeal muscles, in which false membrane, diphtheria, or exudation plays no part.

The treatment of this affection is simple. A smart emetic is indicated at the outset. The choice lies between Ipecacuanha, Tartar Emetic, Sulphate of Zinc, Sulphate of Copper, Apomorphia, Squill, or Mustard and hot water, with mechanical tickling of the fauces by a feather.

Ipecacuanha—5 grs., or drachm doses of the wine—may be given every 15 or 30 minutes to a child of two years old. $\frac{1}{2}$ gr Tartar

Emetic may be given in solution, or half-drachm doses of the wine every 15 minutes, till vomiting supervene.

The following mixture is more valuable than either of its active ingredients when given alone. It may be given to a child one year old.—

R. *Vini Antimonialis* Div. (i.e., gr. i.).
Vini Ipecacuanhæ Div.
Syrupi Scillæ Div.
Aquæ Destillatæ ad ℥iii. *misce.*

Fiat mistura. Signa.—"A tea-spoonful every 15 minutes till vomiting occurs, then half a tea-spoonful every 2 or 3 hours whilst the cough lasts."

Sulphate of Zinc in 3 grain doses, or the Copper Salt in $\frac{1}{2}$ to $\frac{1}{4}$ grain doses acts more promptly, but the after-nauseating, expectorant action of the Ipecacuanha and Antimony is most valuable as the dry, swollen, or congested condition of the mucous membrane is relieved, and the secretion of mucus increased.

After the establishment of free emesis the symptoms of laryngeal spasm generally rapidly subside. It will be found wise to continue the use of expectorants for a few days longer, to keep the child well clad and confined to the sick room, the atmosphere of which should be warm and moist, and due precautions should be taken against future attacks, which are apt to be easily induced by even mild attacks of catarrh from exposure to cold and damp.

Whilst the action of the emetics is being established, the child may be plunged into a warm bath, and after being rubbed dry and placed between blankets a hot poultice may be applied round the throat, or Graves' method may be tried of applying a sponge squeezed out of very hot water, and kept in close contact with the laryngeal and tracheal region, and renewed every few minutes till thorough reddening of the skin be produced.

Marshal treats spasmodic croup very successfully by Nitro-glycerin. Half a B.P. tabloid may be given to a one-year-old child every ten minutes. Nitrite of Amyl may be inhaled in urgent cases where swallowing is difficult.

True Croup, formerly regarded as a simple, non-infectious inflammation of the larynx generally eventuating in the formation of a false membrane, is now by the bulk of English writers accepted as the result of a genuine infection and growth of the Klebs-L. bacillus in the larynx and trachea. This is following the Continental teaching of the last thirty years, and is, in the writer's opinion, probably a mistake. Every physician can recall the clinical picture of true croup (often fatal) unassociated very generally with infection and often without any evidence of a membrane, and often constantly met with in districts where

diphtheria was unknown, or in the absence of epidemics in districts where the ordinary form of diphtheria is only seen epidemically. There is clearly in the writer's opinion three very different diseases commonly met with and treated as True Croup, viz.—(1.) Cases of genuine laryngeal diphtheria often with extension to the trachea, and commonly, but not always, originating in the pharynx. (2.) Cases of mixed infection where the true Klebs-L. bacillus is found with cocci (staphylo and streptococci). (3.) Cases which have no connection with the specific bacillus, but in which various cocci and harmless micro-organisms may be seen. This latter class is clearly described by Lennox Browne, who calls it Pseudo false or non-bacillary Croup—an unfortunate name, as it is liable in this way to be confused with the well-recognised false croup referred to on the previous pages.

In the majority of cases where the physician is called upon to treat a case of true croup in this country, he is probably dealing with a serious non-contagious acute inflammation of the larynx in which there is probably a false membrane beyond his sight or reach. Fortunately, clinical experience, whilst throwing difficulties in the way of the acceptance of one pathological theory embracing all forms of true croup, does not paralyse our efforts in treatment since it proves that all varieties of the disease are benefited greatly by the new serumtherapy which has given such brilliant results in diphtheria.

If the case be seen at the very beginning of the attack (which is rare, as the symptoms of true croup are more insidious and less alarming than in false croup), an emetic should be at once administered. The mechanical act of vomiting clears the air passages of all secretion, and the after-effects of the nauseating expectorant are most valuable in modifying the nature of the inflammatory or congestive action and liquefying the expectoration or thickened secretion of the parts. The physician must be guided in his choice of an emetic by the features of the individual case, and as a rule, the remarks made upon this detail, when speaking of the treatment of false croup, are also applicable here. Tartar Emetic alone, or in combination with Ipecacuanha, is the most reliable method of producing emesis at this stage.

Much mischief may be done by pushing this remedy, though in spurious croup there is little danger of overdosing with emetics, because the attack is a short one, and there is little to be feared by depressing or exhausting the patient's strength.

With true croup the case is different. The siege is a much longer one, and everything that draws upon the slender resources of the little patient must be avoided, and his strength jealously watched, no unnecessary expenditure of force or energy being permitted. Hence, after an early emetic, further administration should be suspended till there are signs of the formation of a membrane. Antimony, in large and repeated doses, is therefore contra-indicated.

Having then decided upon an emetic and whilst awaiting its action the physician proceeds to carry out the other important indications in the way of treatment. The patient is put to bed, and the temperature of the sick room raised to 60° or 65° F. by the combustion of coal in an open grate. The use of gas and other stores is to be discountenanced. Should the patient be a very young child or infant, or should it exhibit much restlessness, it will be found a wise course to undress it completely and put on a white flannel night-dress, and wrap it up in a warm blanket and place it upon the knee of a good nurse. The air of the room must, as far as possible, be saturated with steam or aqueous vapour. This is best done by the ordinary bronchitis kettle, or, in its absence, by fitting a tube of lead, tin, or even paper upon the pipe of an ordinary kettle, and leading the steam within safe distance of the patient's face.

Where the child can be placed in its cot, and a canopy made by hanging sheets over and around it, a moist and warm atmosphere can be easily maintained for any length of time. Where this is not practicable the nurse and child may be surrounded by tall screens, inside which the tube from the kettle may be brought. The various inventions for boiling water and creating steam—by the combustion of gas, paraffin oil, and methylated spirit—in the sick room should be avoided, as the air may be rendered dangerously impure in this way, and it should never be forgotten, as it too often is, that the purity of the air is of vital importance to the patient, who can only get a limited quantity into the lungs at each inspiration.

The ventilation of the room is an important matter for this reason, and the physician should superintend these arrangements himself. It is a wise plan to strictly insist that as few persons as possible be allowed to remain in the sick chamber for any length of time, and the temperature of the room should never be allowed to vary, if possible, more than a few degrees.

The diet from the very first should be sustaining and stimulating. Milk in various forms, and peptonised if necessary, will be the most appropriate. Beef tea, beef jelly, meat juices or chicken jelly should be given in small quantity and often, the physician remembering that soon a time may come when appetite and digestion will lag, and when it will be both difficult and injudicious to force the nourishment upon the little patient.

A skilful nurse will know when to present it, and if emetics must be continually administered she will give aliment as soon as possible after the effort of vomiting has subsided, so that digestion may be as little interfered with as possible. As the child gets peevish it may refuse all food and ask for water, if this be freely given and thirst assuaged, the child may very soon have no desire for anything else, and feeding be at a standstill. It will thus be wise to only give milk or liquid nourishment all through. Stimulants at a later stage may be indicated, and if so they should be freely

given, and if possible always along with the food. Beef wine with extract of malt is very suitable, and generally is relished by children. Rennet may be added to the milk, or pepsin or pancreatic liquor may be mixed with the beef tea; and later on, when swallowing becomes difficult owing to the dyspnoea, or when great nausea or vomiting prevents the food being got into the stomach, rectal feeding with peptonised food should be tried. For this purpose nutritive suppositories are exceedingly convenient. It may be advisable in some cases to stop all feeding by the mouth for a time, say 8 or 10 hours, and the nutritive suppositories if retained will well support life alone; by this time the child may greedily take food.

The generally accepted diphtheritic origin of true croup has led to the routine employment of Antitoxin injections, and these should be always resorted to at the earliest possible period in the disease. Indeed, since the antitoxic serum is perfectly harmless, the physician should administer a dose of at least 1,500 units without waiting for any signs of false membrane, as soon as he sees that he is treating a case of true croup. Double this amount may be given after the expiration of 12 hours if the symptoms are not yielding. Excellent results follow this routine, but it is certain that it should in no way supersede the older remedies, which should still be used in conjunction with it.

Before mentioning the different drugs generally given internally for the relief of croup, *local* treatment may be considered. Hot poultices to the throat and neck afford some ease, and may do good by relaxing spasm. Hot compresses, or a collar of spongopiline squeezed out of hot water, or a sponge similarly treated, are more convenient; sometimes the appearance of a hot poultice sends the patient into a struggling fit, which always does harm. Cold compresses, or Leiter's coils in some cases afford comfort, and if so they may be persisted in with advantage.

Cauterisation of the larynx with Nitrate of Silver or other caustics should never be attempted, and even where the disease is evidently depending upon diphtheria, and the membrane is visible in the pharynx, cauterisation is a questionable proceeding in the case of young children. Good results have followed so-called caustic applications, but it is probable that these results have been obtained through the *antiseptic* quality of the drug. As the membrane is not visible in many cases of croup, the value of such applications need not be here discussed.

Various substances in the form of vapour or spray have been locally applied. Of the vapours the following have been used, either sprinkled about the room, added to boiling water, or inserted on lint into the receptacle in the nozzle of the pipe of the bronchitis kettle—Eucalyptus Oil, Creosote, Iodine, Bromine, Carbolic Acid, Tar, Terebene, Turpentine, Tinct. Benzoin. Co., Chloroform, &c.

It is very questionable if any good ever results from these

vapours: undoubtedly harm arises if the concentrated vapour of any of these substances reaches the larynx. A little turpentine or eucalyptus is of use by assisting to keep the air of the sick chamber sweet and pure. Oxygen inhalations may be useful in the later stages. Rothe recommends the vapour produced from heating a small quantity of Calomel upon a plate under the bedclothes.

Sprays have been much used in croup and also in diphtheria, and if judiciously employed much good may be achieved by them. Those who believe in the diphtheritic nature of croup place most faith in their use.

The following is the best of local spray applications:—

R. *Acidi Carbolici* ʒj.
 Glycerini Boracis ʒj.
 Aquæ Rosæ ad ʒviii. *misce.*

First solutio. Sig.—“To be used every half hour as a spray”

Various substances are employed in this way, with the view of causing solution or disintegration of the membranous exudation believed to be present. Lime Water and Lactic Acid are the most frequently used. The following is used on the Continent:—

R. *Acidi Lactici* ʒiii.
 Aquæ Calis ʒviii *misce.*

Carbolic Acid (1 drachm to 10 ozs.) is also used, and Sulphurous Acid has been tried, but it might cause dangerous laryngeal irritation. Pure liquid Vaseline or Paroleine spray is soothing, and can do no harm. Papan, Pepsin, Trypsin, and other substances, which have been used as direct applications to diphtheritic patches in the pharynx and on the tonsils, have been recommended in croup, but their use has not been attended with any benefit. Of all the remedies employed locally, the weak spray of Glycerin and Borax or Carbolic Acid is the least objectionable and most likely to be followed by some benefit. A spray of Corrosive Sublimate (1½ grs. in 10 ozs.) has been very highly spoken of, but the writer has no experience of its action in young children.

On remedies for internal use in the treatment of croup there is practically no end. Many of these have been urged upon very slender theoretical grounds, and chiefly with the view of destroying germs or bacilli, which are supposed to be the sole cause of the disease. Only the most important will be mentioned.

To return again to the management of the case. After the administration of the first emetic, as mentioned on page 182 various methods of treatment may be selected by the physician. The writer, after trying many of these, is inclined to advise the use of

a simple expectorant, which may be given every three or four hours without producing nausea or vomiting; and if symptoms of dyspnoea or embarrassed breathing appear, the same mixture may be given every ten or fifteen minutes till vomiting supervene.

This treatment has the merit of doing no harm, and does not interfere with the more vital matters of food, stimulants, steaming &c. A mixture like the following may be given to a child two years old:—

R. *Vini Ipecacuanha* ℥vj.
Spirit. Ætheris Nitrosi ℥iv.
Spirit. Ammonia Aromat. ℥iii.
Syrupi Tolulam ℥j.
Aquæ Camphoræ ad ℥iv. *mixe.*

Signa.—"A tea-spoonful in an equal quantity of water every 2 or 3 hours, and if the breathing becomes distressing, every 15 minutes till vomiting occurs."

If feverishness be marked, $\frac{1}{2}$ minim Tinct. Aconiti may be added to the first six doses. Should the distress, cough, and dyspnoea demand the continuous use of emetics, one which will act quicker than the above is necessary. Tartar Emetic is too depressing, and cannot be safely administered in the later stages of a disease characterised by great depression and muscular prostration. Apomorphine is open to the same objection. Alum in doses of half a tea-spoonful with Syrup every 15 minutes is extolled as a safe emetic in croup.

Sulphate of Copper, $\frac{1}{2}$ gr. in solution, given every ten minutes to a child one year old, was Trousseau's favourite remedy for producing vomiting in croup. It is not so safe as the Sulphate of Zinc, which may be given in doses of 3 grs., and repeated every ten minutes till vomiting results.

Where Ipecac is followed by too much depression, or where its action is too slow in the later stages of croup, the physician will be wise in discarding all emetics except the Zinc Sulphate.

Oil of Turpentine, in tea-spoonful doses, has given very striking results in the hands of Lewentauer. Calomel, in $\frac{1}{2}$ to $\frac{1}{4}$ gr. doses every two hours, was given by Niemeyer, and some still follow his rather questionable practice.

Corrosive Sublimate, by way of variety, has been substituted in the Calomel treatment, with the usual report, that it "has been followed by success," the dose for infants (one year old) being about $\frac{1}{2}$ gr., taken during the 24 hours. It has been combined with Ichthyolunctions and Antipyrine enemata. The Bichloride of Mercury has been also given.

Iodide of Potassium, Sulphide of Calcium, Tincture of Iron, &c.

every remedy used in diphtheria successfully, have been administered with reputed advantages in croup.

Pilocarpine has been given with the idea of causing detachment of the false membrane, but the doses likely to have any effect in this direction would probably cause serious cardiac depression, and it is not finding favour, though at the last Congress in Rome, Székely stated that Pilocarpine was a *specific* for croup, acting immediately, and reducing the mortality to *nil*, whether given hypodermically or by the mouth.

Sooner or later, in the majority of cases, the obstruction to the breathing inducing progressive asphyxia will demand operative procedures, and serious responsibility rests upon the physician who delays his decision on this point as the mortality rises enormously with the delay. The question of Intubation or Tracheotomy is a serious one, and each have their advocates. Until the introduction of the serum treatment the mortality after Tracheotomy was exceedingly great in young children, some surgeons rarely having a single success, and in former editions the writer, after giving his own series of failures, stated that he only knew of one successful tracheotomy in 20 years. All this is changed, and where the serum therapy fails to cure the disease without an operation, it certainly enormously increases the hopes of a recovery after tracheotomy. A large dose, 3,000 units, should be given before operating if this has not already been done a few hours previously.

Every physician should have a clear idea of the steps of the operation, because circumstances may so place him in a position where it will become his duty to operate and save life; before a surgeon can be procured it may be too late.

The first question is the one of anaesthesia. Speaking generally, chloroform should be administered, but in many of the cases of croup or diphtheria that come under the surgeon, the disease has advanced so far that partial anaesthesia has already taken place owing to the venous condition of the blood, and the operation may be immediately commenced without waiting on chloroform.

Laryngotomy should be left out of the question owing to the anatomical condition of the air passages in young children. The trachea should be opened, and the opening in the tube should always be made above the isthmus of the thyroid gland. Sometimes the isthmus must be divided if the space is limited, but the operation in young children should never be attempted with a view to open the trachea and insert a tube below the isthmus. This is owing to the shortness of the neck in children. The operation for croup or laryngeal diphtheria in such cases is crico-tracheotomy or laryngo-tracheotomy.

The patient should be placed in the recumbent position, with his thorax raised and the head extended. The operator, standing on his right, feels for the cricoid cartilage, and makes an incision having this point rather above its centre. The incision must be

fair in the middle line, and may be made through all the soft parts in front of the trachea. About $1\frac{1}{2}$ inches will be long enough. The trachea should be felt for by the tip of the left index finger, and any veins drawn aside. When its rings come into view, the point of a sharp scalpel is inserted, and the first 3 rings, with the cricoid, should be divided from below upwards. If the trachea does not prominently present in the wound, it may be caught up by a sharp hook and drawn forward, while the scalpel, with the edge upwards, cuts an opening through the upper rings. After the air and mucus have bubbled into the wound and been expelled by the expiratory efforts, the tracheotomy tube can be inserted. The opening in the trachea must be free enough to take in as wide a tube as possible, and it is a mistake to make a very limited incision, as it greatly increases the difficulty of inserting the tube. Sometimes difficulty will be experienced in getting the tube inserted owing to the bubbling up of secretions into the wound, and the writer was once forced to apply his lips to the tracheal incision before he could accomplish this in a diphtheritic case seen with Dr. S. B. Coates. This should never be done, however, owing to the risk of infection, and suction instruments can be had for clearing out the canula of the tracheotomy tube which may be used in an emergency of this kind.

After the tube is placed *in situ* and fastened by broad tapes passed round the neck, the little patient is put into his cot, or allowed to sit upon the nurse's knee, the space around them being enclosed by sheets and canopied over, and the tube of the bronchitis kettle is brought inside the enclosure, thus ensuring a moist, soft, and warm atmosphere.

The temperature of the room must be always watched by the thermometer, and never allowed to fall under 65° F. If the patient be old enough to be trusted not to pull at the tube, the ordinary "croup cot" saves much trouble, but if very young and restless, the nurse's knee is the safest place. It is absurd to attempt to keep some children by force in bed, and some will not tolerate the confined moist space. A large piece of muslin squeezed out of hot water may be folded and laid over the neck, covering the wound and tube in such cases.

The nurse should be directed to constantly cleanse the opening in the tube, and if it gets plugged by mucus or shreds of membrane she may occasionally insert a feather previously dipped in any weak disinfectant, and fish about for any obstruction, which is easily entangled in its plumules. The spray of weak Carbolic Lotion or Bimiodide of Mercury (1 in 4,000) may be constantly used, and will be of great service in keeping the skin wound healthy and sweet.

The tube may be finally removed about the sixth day in most cases, and if its aperture be blocked by a plug of lint, and the patient is found able to speak and breathe, it can be removed at any time after the first 3 or 4 days.

After the operation the treatment must be scrupulously continued as before—food, stimulants, and a mild expectorant given regularly. Iron may now be ordered with great advantage. For a child two years old the following may be employed—

R. *Tinctura Ferri Perchlor.* 3iss.
 Vini Ipecacuanhæ 3ii.
 Potassii Chloratis 3j
 Glycerini et Aquæ ad 3ii *misce.*

Fiat mistura. Sumat 3j ex 3ii. aquæ omni quarta hora.

The method of intubation of the larynx, first performed by Macewen, and now perfected by O'Dwyer, is especially valuable (according to the reports of those who have performed the operation) in the case of children under 5 years of age. The child is made to sit bolt upright on the lap of a nurse with the head slightly backwards. The mouth is opened widely, and a gag inserted. The operator introduces his left index finger, and hooks the epiglottis forwards, whilst with the right hand he inserts a suitably-sized O'Dwyer's metal tube upon the point of an "Introducer," passing it under the tip of the left index finger into the larynx. The introducer being withdrawn, the tube is pushed home with the left index finger. After a few moments' coughing the tube is generally easily tolerated.

Its extraction is difficult, and special forceps are devised, made so as to enter the upper orifice of the tube, guided by the tip of the left index finger. Once inside the tube, the blades are opened and the tube removed. Dr Waxham has invented an artificial epiglottis of metal, which is attached to the upper end of the tube. It enables the patient to take liquid nourishment with ease.

The great advantage of intubation, which is steadily gaining ground, is that it will certainly be performed at a much earlier stage of the disease than tracheotomy. There cannot be a doubt that the high mortality after a cutting operation is largely owing to the objections of the patient's friends, who refuse permission till too late. (See page 187.) Statistics show that, all round the mortality from tracheotomy and intubation are very much alike, but there is a decided advantage upon the side of intubation when the very early ages are contrasted, but the mortality rate of both operations is enormously lessened by the serumtherapy.

Millard in the *Ed. Med. Journal*, 1898 gives twelve strong reasons in favour of intubation, and regards it as the operation for an emergency. The operation is an easy, rapid, and simple one and the operator acquires the knack of doing it. The one great drawback to it is the danger of the tube becoming obstructed, and this requires the interference of the surgeon himself.

CYSTITIS—See Bladder, Inflammation of.

back in bed by gentle persuasion and mild restraint than to allow him to once get up and initiate a struggle, when considerable force will be necessary to get him again into bed. Where this method fails with a restless patient a sheet may be so tied across the bed or tucked in that his movements will be considerably hampered. The straight-jacket—rightly regarded by every physician with disfavour—must in rare cases be employed, and the writer has seen it induce rest and calm, without which the patient's struggles could not have been subdued, and death from exhaustion would inevitably have supervened. Such cases are, however, rare and are no justification for the coarse or cruel abuse which sometimes may be noticed at the hands of untrained nurses or attendants.

The physician should insist that save one relative or friend who may have the right of passing in and out of the sick-room all visitors must be strictly forbidden, and the most complete rest and quiet made to prevail.

Food should be administered with regularity, and it should be of the most sustaining and stimulating kind. Solid food, owing to the state of the digestive organs, cannot be taken. Strong soups, beef tea, beef essences, and beef jellies, with an unlimited supply of milk, should form the diet of a patient during the acute stage of the disease. Feeding by the nasal tube and per rectum may be demanded.

Attention to these measures will safely carry a large majority of patients through their attack, and without any narcotics or hypnotics, upon the third night or fourth morning the patient, exhausted and wearied by his restless movements, falls into a natural slumber of variable duration, from which he generally awakes comparatively well and free from hallucinations.

To properly treat the disease in all cases, the physician must keep this spontaneous tendency towards recovery always before his mind. Many cases, nevertheless, will demand some further therapeutic measures, and few instances will occur in which some of the distressing symptoms may not be removed or modified by judicious administration of medicine.

The first question which the physician must decide is the one of alcoholic stimulants, and, as mentioned under Alcoholism, the popular prejudice is strongly against the withdrawal of the patient's favourite beverage. In many instances it will be found that he has already ceased drinking just before or soon after the first symptoms of the affection have declared themselves. The distaste for alcohol is often the first symptom of the disease. The physician may be certain that in the great bulk of cases alcohol will do no good, and in very many, especially in young subjects in their first attack, its administration will do harm.

The case is different with older patients, especially those who have taken alcohol for long periods, and in whom symptoms of pneumonia or of cardiac failure manifest themselves. Here alcohol must not be withheld unless at great risk; but such cases

uncomparatively rare and even in them the alcohol should not be started at the very beginning of the attack. When stupor is part of the case or when there are grounds for suspicion of stupor with failure of pulse alcohol must be given freely in conjunction with large doses of chloral or spirit of Aconite, digitalis, and a hypodermic of strychnine.

The great question in the treatment of delirium tremens is the use of narcotic or hypnotics. There cannot be a doubt but that some cases would be better with them all through the attack, and it is equally certain that they should not be given in any case at the beginning. It appears probable that a patient who would not fall into natural sleep at the first onset of delirium, and not be sent to sleep for several weeks after. It is almost nightly probable when sleep has followed the onset of a narcotic in the early stage that the case has changed to be one of those mild forms of the affection which would have terminated in sleep if left to itself. Should hypnotics then be administered at all in delirium tremens? The answer to this question must be in the affirmative.

It must also be remembered that drugs like the Bromides and Hyoscyne, even if they fail to induce sleep, may nevertheless quiet nervous excitement and husband the strength of the patient.

The writer has satisfied himself that even a very short curtailment of the period of excitement in bad cases may save life, and one cannot help reflecting after witnessing the death of a patient, say upon the fourth day of a restless and exhausting delirium, that had sleep been induced by any means, even by Chloroform, a short time before the fatal termination was due a different result might have been obtained. Had the patient lived for another hour possibly sleep might naturally have occurred and the question in such terribly serious cases is can sleep be artificially induced at even a brief period before it naturally might fall due? This seems so highly probable that one must be undertaking a very serious responsibility who would withhold all narcotic or hypnotics from a patient sinking from the exhaustion caused by a restless delirium and want of sleep.

At the same time, it must be remembered that many deaths have been attributed to the free use of the narcotic and that Wilks stated he had seen many cases of delirium tremens sent to their last sleep by opium. With this statement all observers would agree had Wilks spoken of chloral instead of opium.

The physician thus finds himself placed in a grave difficulty, when dose after dose of narcotic fails to induce sleep in a patient apparently sinking from the exhaustion which sleep would soon banish.

The difficulty is made no less by the knowledge that owing to the state of the digestion and absorption these doses may lie in the stomach or intestines unabsorbed for a time and then may all rapidly enter the circulation at once, hence solid opium should

never be administered in this condition, and hypodermics of morphia are clearly indicated when absorption is in abeyance.

Another plea for the use of narcotics in this affection might be made out by stating what the writer believes to be the fact in some cases, that when sleep does occur it is sounder and more lasting, and hastens the recovery of the patient.

If the judgment of the physician leads him to believe that a moderate hypnotic will be beneficial in a given case, he should not think of giving it sooner than 24 or 30 hours after the onset of the symptoms.

Early restlessness and activity may be to some extent benefited by full doses of Bromide, though it fail to induce sleep.

Of all the hypnotics used none is so dangerous as Chloral, though this was the drug considered by Anstie to have the power of cutting short the disease, and the drug for which he thought there was a marked tolerance in delirium tremens. The writer has seen it tell with fatal rapidity upon the heart in this disease, and he has long since ceased to prescribe it. Chloralamide is not so treacherous, but it requires watching.

Forty minims of Laudanum or Liquor Morphia may be given about the ordinary sleeping hour of the patient upon the second night of his attack and if sleep does not follow it should not be repeated till the early hours of the morning, and not again till bedtime the following night. Should the state of affairs be the same upon this night as upon the second, one dose of 30 minims may be given early upon the fourth morning. If sleep does not supervene by the fourth night (say 72 hours after the onset of the disease), the situation will become serious, and the full dose may be again repeated, to be followed by 20-30 minims every four hours till sleep comes on. Should excitement follow each repetition of the opiate, its administration should be suspended, and it has been long observed that rapid improvement often follows one or two doses of Tartarised Antimony ($\frac{1}{4}$ - $\frac{1}{2}$ gr.), or the Hot Pack may be tried.

It is advisable to clear the bowels out by a smart purge before beginning the opiate treatment, and if the physician suspects that the remedy is not being absorbed, he may give a corresponding amount by the hypodermic needle when the next dose falls due in 4 hours. Wood states that "the combination of chloral and morphia far exceeds in efficiency and general applicability all other hypnotics," though some physicians believe that this combination is far more dangerous than full doses of either drug when given separately.

Paraldehyde, in 60 minim doses, Sulphonal, in 40 grain, and Trional, in 30 grain doses, have been used to great advantage, and many physicians are content to treat all cases with one or other of these drugs. They are, moreover, perfectly safe in the above-mentioned doses.

Hyoscine hypodermically, (1/10 gr.) has been tried as a hypnotic, has given splendid results in delirium tremens.

Digitalis, in very large doses, has been freely given, and it is rather surprising to find that a heavier mortality has not been reported after doses of 240 minims of the tincture every 4 hours. These heroic doses have unfortunately been followed by some dangerous symptoms which may have the effect of preventing the administration of the drug in delirium tremens. It is, in reasonable doses, a most valuable remedy where there are signs of cardiac failure, but to be of use it must be given early, as the slowness of its action, which is often overlooked by physicians, renders it of little use in sudden failure of the cardiac muscle.

Strychnine acts much more quickly, and has an antagonistic action to alcohol. (See under Alcoholism.) The Tincture of Nux Vomica may be given in doses of 15 minims every 4 hours with 10 minims of Tincture of Digitalis, and, where cardiac failure threatens seriously to cut off the patient, in addition to the free use of Whiskey with Ammonia, as already mentioned, it is a good practice to give a large hypodermic dose of Strychnine, 1/10 gr. will be enough, and may be repeated in 3 hours. The doses mentioned in many text books (1/20-1/10 gr.) are useless in a condition like this. Hot Mustard poultices to the cardiac region and spine should be used at the same time.

The following is a good formula :—

R. *Liquor. Strychnina Hyd.* 3iiss.
 Tinct. Digitalis 3iv.
 Hyoscina Hydrobrom. gr. 1/4.
 Tinct. Card. Co. ad 3iij. *misce.*
℞. mst. St. 3j. ex aquâ secundis horis.

Capsicum, in 20 grain doses, has been strongly recommended to produce sleep, but the writer has been disappointed in the results obtained by it in hospital practice, and, if there be any chance of acute gastritis supervening upon the debauch which led to the attack of delirium, he fears it might do harm by adding fuel to the fire. Nevertheless, good results have been reported in the hands of reliable authorities, even when gastritis was a prominent symptom. In the early stages 2 oz doses of Mindererus Spirit may be combined with it to promote elimination of retained alcohol.

Belladonna, Hyoscyamus, Arnica, Sumbul, Lupulin, Stramonium, and many other remedies of the same class, have been used with varying success.

Albuminuria may indicate kidney lesion, which seriously complicates the attack, and uræmic convulsions may occur. They should not be mistaken for epileptic seizures, which also often

occur. A convulsion coming on, accompanied by a large amount of albumin in the urine, should be promptly treated by Saline purgatives and a Hot Mustard pack, and obviously Morphia is contra-indicated. (See Bright's Disease.)

Complications, as they arise, must be treated upon the general principles mentioned under the head of each. As a rule, they are an indication for stimulants. Pneumonia is especially serious.

Delirium tremens, the result of an injury or accident in intemperate and irregular living subjects, is very common in the surgical wards, and generally turns out a grave affection. It may come on with alarming rapidity, and it is the writer's experience that the delirium in these cases is often of a more active and dangerous kind, and free stimulation is much more frequently indicated in this group of cases than in the ordinary medical varieties of the disorder; this is especially true when erysipelas supervenes.

DEMENTIA.

In the acute variety of this affection, much can be done by judicious treatment. The essence of all treatment lies in forced feeding, and if carried out systematically and persisted in, even when the case appears hopeless, great improvement and even permanent cure often results. The food should be given in the liquid form, and, practically, in unlimited amount. By the India-rubber tube of the stomach pump, 6 to 8 pints of peptonised milk may be put into the stomach daily.

Rectal feeding may be necessary in extreme cases.

There is, however, no remedy like Massage but this should only be attempted when the forced feeding is being freely carried out. Thyroid feeding has occasionally proved successful by making a profound impression upon the general metabolism, and where the disease arises in the progress of myxedema this remedy will give sometimes startling successes.

Malt Extracts, Cod Liver Oil, Iron, Quinine or Bark, with Dilute Nitro-Hydrochloric Acid, alternating with small doses of Arsenic, may be given with advantage.

Stimulants should, as a rule, be freely given at first till the activity of the alimentary canal and the nervous system be roused from its torpor by the increased nutrition.

The constant current, 20 Leclanche cells, may be applied to different parts of the body for a period of 15 minutes twice daily, and Static Electricity has a powerful influence over the general nutrition.

The patient's body should be enveloped in thick flannels, and artificial warmth is almost always required.

Where the dementia is secondary to some brain disease or functional disorder, the treatment of the original affection is indicated. In mild cases following mania, the patient should be removed from confinement, and, if his means permit, great benefit

may accrue from travel and change of scene. In syphilitic patients a mild mercurial course, and in cases of tumour large doses of Iodides may prove most valuable.

DENGUE.

The patient should be sent to bed and fed on liquid diet, and as in ordinary short febrile affections he may have a simple diaphoretic mixture preceded by one smart purge.

Quinine in 5 grain doses may be maintained as long as the temperature keeps high, and the new antipyretics are of value, especially as the initial fever is short and sharp. Sometimes the cold pack or douche or sponging must be resorted to when 105° F. is reached. Salicylate of Soda has given good results.

Belladonna has been found of great use for the relief of the joint pains, and may be combined with Opium thus:—10 minims each of Laudanum and Tincture of Belladonna may be given every 2 or 3 hours for 4 or 5 doses with marked benefit. After the subsidence of the acute symptoms, Bromides and Iodides are valuable, though generally anti-rheumatic remedies afford little relief to the arthritic complications. The convalescent stage may be managed upon the general principles indicated in the treatment of our own specific fevers.

DENTITION, Disorders of.

A great deal of importance has been attached to the conditions often found associated with or attributed to the eruption of the milk teeth, and various disorders having nothing whatever to say to dentition are being constantly brought before the physician as cases of delayed or irregular teething. Nevertheless, it is a daily matter of observation that certain symptoms appearing at this period demand prompt treatment.

Convulsions may be fairly traced to this source, and under that heading the indiscriminate scarification of the gums has been dwelt upon and the evils resulting therefrom mentioned. (See Convulsions, page 172.) Where the tooth is near the surface it should be released by scraping through the thin tissue over it down by the sterilised finger nail. Where the gum seems very tender and the tooth too deep for scarification, a little 1 per cent. Cocaine Solution may be rubbed over it.

The chief indications for the treatment of the various combinations of symptoms noticed at this period in young children may be easily decided by a study of the mechanism causing these disturbances. The very marked impressibility of the different nerve centres in the young child, owing to developmental causes, renders any peripheral irritation liable to be followed by phenomena more or less general. This impressibility of the nervous system may be controlled or altered by drugs, and there are few conditions in which more immediate and striking relief may be harmlessly obtained. Opiates should not be employed; the relief

they afford is dearly purchased, as they leave the nerve centres still more susceptible to impressions which in the normal condition give rise to no reflex manifestations.

Bromides are invaluable, and no harm can follow the administration of full doses of the Potassium or Ammonium Salt. The domestic remedy—Nitrous Ether—has a decidedly beneficial effect, the writer thinks that its soothing influence depends upon its power of causing dilatation of the small vessels. It appears to do good also in causing the skin to act, and thus relieves the irregular fever so constantly found associated with symptoms depending upon delayed dentition. Peevishness, restlessness, wakefulness, muscular twitchings, night terrors, vomiting, diarrhoea, and the characteristic series of teething troubles often rapidly yield in an infant of about 12 months old to the following simple combination—

R. *Ammon. Bromidi* gr. xxx.
 Spir. Ætheris Nitrosi ℥iss.
 Liquor. Ammon. Acet. ℥iv.
 Syrupi Simplicis ℥iv.
 Aquæ Chloroformi ad ℥ii. misce.
Fiat mistura. Sumat ℥j. omni secunda hora.

The bowels should be cleared out by a tea-spoonful of Castor Oil, preceded by a dose of 1 grain of Grey Powder. It is a good plan to give the Mercurial in a tea-spoonful of Syrup of Senna, and to omit the oil. The Senna can be repeated without the Grey Powder every 4 hours till the bowels act. It is easily taken by all children.

DIABETES INSIPIDUS.

The treatment of this affection is very unsatisfactory, and though many drugs have been used, and successes unquestionably recorded, nevertheless the drug which benefits one case will have no effect whatever upon the case next presenting itself, and we have no real knowledge of the pathology of the affection. Hence the treatment here mentioned can only be a brief list of the drugs or remedies which have been given, with very decided benefit in some cases.

The continuous current has been used in different ways. A strong current is employed, and the best method appears to be by placing the positive pole on the nape of the neck, and the negative over the loins and pit of the stomach, alternately, for four or five minutes at a time.

Some physicians have contented themselves with a weak current, and have passed it through the base of the brain; others report improvement by placing one pole over the loin behind, and the other deeply pressed into the corresponding hypochondrium, galvanizing each side daily for five minutes. In most cases this treatment has signally failed.

Antipyrine has been reported as markedly successful in several recent cases. It should always have an early trial. The daily dose should begin with 30 grs., steadily increased till 60 grs. are reached.

Trousseau's great remedy was Valerian in enormous doses. He administered a drachm of the extract three times a day, and in one case he gave one ounce daily. The nausea which follows is the great drawback. Ralfe administers 10 mins. Tincture of Cannab. Ind. with 6 drs. Tr. Valerian and 30 grs. Bromide at bed-time. Valerianate of Zinc in 10 gr. doses may be given in capsules.

Nitroglycerin has been favourably reported upon. So also has been Ergot and about half the drugs in the B. P.

Suprarenal Extract has disappointed expectations. The writer has tried it without the least benefit.

Amylene Hydrate has been one of the newest additions to the list, in doses of about 1 dr. at night, and Paraldehyde has its advocates.

Roberts, noticing how often the disease was relieved by the presence of some intercurrent inflammatory affection, was led to apply a large blister to the pit of the stomach with some benefit.

Opium, Morphia, Codeine, and other narcotics generally do harm. Iron, Strichnine, Gallic Acid, Creosote, Alum, Belladonna, Muscarine, Pilocarpine, Cream of Tartar, Nitre, Salts of Silver, Mercury, Arsenic, Zinc and Gold, Bromides, Iodides, Permanganate of Potash, and many other drugs have been at times found useful in diminishing the amount of the urine. Some cases are upon record where, after failure of all drugs tried, rapid improvement has followed a change of air to the sea-side.

Warm clothing should be insisted upon, and the general health carefully looked after, signs of emaciation being treated by Cod Liver Oil, and the usual remedies applicable in the treatment of wasting diseases.

A diet of dry or solid food with little liquids always causes rapid diminution in the amount of water passed, but produces such intense discomfort and depression that as a method of treatment, it has to be soon abandoned in each case. Where phosphaturia exists, Opium and Codeia may be tried for a short period, and then food rich in phosphates may be given, and whole-meal flour is indicated. There is little benefit from ordinary phosphates.

DIEET.

The most important portion of the treatment must be a well-regulated diet. If this be not strictly attended to, drugs will avail little. The physician will always keep before him the main object of furnishing for the patient a dietary as far as possible containing the least amount of sugar or starch, or substances easily convertible into sugar. But no two cases of the disease will thrive best upon an exactly similar diet table, and in this comes in the secret of

treating the affection successfully. By daily estimation of the amount of sugar voided in the urine, and by weighing the patient at short intervals, the diet may be adjusted from time to time, so as to make life comfortable, and in many cases lead to a complete and permanent cure. The amount of sugar excreted will often convince the physician that some articles can be taken with safety and benefit by one patient which may seriously increase the disease in another.

The best method for practical purposes of estimating the daily excretion of sugar is the one introduced by Roberts. It can be carried out by any intelligent patient (whenever it is wise to trust a patient with the details of his own ailment). It is carried out in the following manner :—

About 4 oz. of the saccharine urine are put into a 12 oz. bottle, and about the size of a small walnut of German Yeast is added to it. The bottle is then covered with a nicked cork (which permits the escape of carbonic acid), and set aside on the mantel-piece or other warm place to ferment. Beside it is placed a tightly corked 4 oz. phial filled with the same urine without any yeast. In about 24 hours the fermentation will have ceased, and the scum cleared off or subsided. The fermented urine is then decanted into a urine glass and its specific gravity taken. At the same time the density of the unfermented urine in the companion phial is observed, and the "density lost" ascertained. Fermentation is generally complete in about 18 hours, if the locality be sufficiently warm; and it is desirable to remove the two phials into a cool place two or three hours before the densities are taken.

The difference between the two densities—i.e., the density *before* and *after* fermentation—will give approximately the number of grains of sugar in each fluid ounce of the urine. Thus, suppose that the unfermented sample by the urinometer registers S.G. 1050, and that the fermented sample registers S.G. 1020, the urine for practical purposes may be regarded as containing 30 grains of sugar per fluid ounce.

By multiplying the total number of ounces passed during the twenty-four hours by 30, the total amount of sugar in grains will be easily obtained. Thus the physician will have a fairly accurate method by means of which he can determine the result of dietetic and medicinal treatment without which he would have to grope his way in the dark a good deal.

In selecting a diet, the following must be avoided :—Most vegetables (exceptions will be afterwards enumerated), especially Potatoes, Turnips, Cauliflower, Carrots, Peas, Beans, Parsnips, Sea Kale.

Fruits—especially all sweet fruits—Apples, Oranges, Pears, Gooseberries, Currants, Plums, and Peaches, must be forbidden. Lépine thinks Apricots are admissible in most cases as their sugar is chiefly levulose.

Farinaceous food must be strictly avoided—thus Corn Flour,

Bread, Rice, Sago, Macaroni and Vermicelli, Tapioca, Sweets, Pastry Puddings, &c.

Of the articles allowable, nearly every animal substance may be freely partaken of—any kind of Meat, Game, Fish, or Poultry, indeed, the only animal products which are injurious and must be avoided are Liver, Molluscs, and Honey.

In the cooking of animal substances, strict attention must be paid to the avoidance of adding any starchy or saccharine flavouring ingredients to the meat. Green vegetables, Cabbage (when quite green), Lettuce, Cress, Spinach, Watercress, Celery tops, Endive, young Brussels' Sprouts, Spring Onions, French Beans (when quite young), and green Artichokes may be allowed in moderate quantities.

Cheese, Cream, Butter, and Eggs may be used in quantity. The question of Milk will be considered afterwards.

If cream be mixed with a large quantity of water and the mixture allowed to stand, the perfectly pure cream devoid of all lactose can be skimmed off, this added to water, with which the white of an egg has been blended, will form a mixture almost identical with good cow's milk. Williamson adds a little saccharin or salt.

There is, after all, but one difficulty in the treatment of diabetes by diet, and that is the question of bread. To provide a substitute for it which will contain neither starch, sugar, nor anything easily changed into sugar, and which will, at the same time, be both palatable and capable of sustaining life, is the great desideratum.

Bran made into cakes by Camplin's method, with eggs, butter, and a little milk, are used, and may be obtained from various makers.

Gluten Bread, made from carefully-washed gluten, in which as little starch as possible is left, is, if made carefully, a palatable substitute.

The writer has had several poor diabetics kept alive upon home-made bread prepared by themselves from the crude gluten obtained from the starch works. This compound is far from being a proper diabetic food, but, amongst the poor diabetics discharged from hospital as incurables, it is the best that can be done for them. He directs them to take 4 breakfast-cupfuls of the finest bran, and a small tea-cupful of the best white Indian flour or meal, and rub these up with 6 oz. butter and a tea-spoonful of bicarbonate of soda. This mass is then made into dough with the thick part of the washed gluten, which has been left to settle in a pail of water over night. This mass is to be rolled into cakes, and baked in a slow oven for two hours.

Gluten flour, as sold, often contains large amounts of starch. Dr V. Fielden has found as much as 68 per cent. in samples obtained from good houses.

Sundby states that the best gluten bread contains at least 25 per cent. starch, and that many samples contain 40 per cent., while ordinary wheaten bread only contains 42 per cent. Ordinary baker's bread cut thin and thoroughly toasted through

and through is undoubtedly much less objectionable than many of the gluten bread, buns, and cakes freely advertised as safe diabetic food.

Alcock found only 27 per cent. of starch in the bread made by the Protene Food Co.

Pavy believes that there is no article of food better suited to the diabetic than the Almond. Its highly nitrogenous and rich oily materials supply him with every want, and from it bread, buns, and cakes can be easily made, which are very palatable substitutes for bread. Purdy also speaks strongly of the almond flour, and shows that it should be prepared fresh, because of its speedy deterioration, owing to the 50 per cent. of oil contained in it. Rubbed up with eggs and well beaten, and a little baking powder added, it may be baked in small tins in any good oven without difficulty.

Saundby recommends for almond cakes—1 lb. ground almonds, 4 eggs, and 2 table-spoonfuls of milk, and a pinch of salt (or saccharin); the eggs to be beaten up, and the almond flour stirred in, divided into cakes, and baked in a moderate oven for 45 minutes.

Soya bread has not maintained its reputation. Kinch has shown that it is rich in starch.

Danype's bread is made with flour obtained from the embryo of wheat, after the separation of its starchy endosperm. It is used in France for diabetics, and is said to be very poor in starch. Furbringer's Gum bread is used in Germany.

Ebstein's Westphalian bread is made from "Aleuronal," a patent gluten flour, consisting of vegetable albumin. R. T. Williams gives particulars about the making of aleuronat into cakes with cocoa nut in the *B. M. Journal*, April 27, 1895.

Desiccated Cocoa Nut may be used, and Saundby recommends—12 oz. with 12 oz. Almond flour, 6 eggs, 4 oz. milk, mixed, divided, and baked for 25 minutes, if a little gluten flour be added and the dough fermented, a good palatable food results.

Levulose and Inulin are recommended, and Hale White suggests the use of dahlia tubers boiled as a vegetable, on account of their starch being in the form of inulin.

Tea, Coffee, and Cocoa made from nibs, may be freely partaken of, sweetened with Saccharin or Glycerin, and containing good Cream. There is little use in trying to diminish the amount of fluid consumed, and thirst may be assuaged by acidulated drinks made with Cream of Tartar, Phosphoric Acid, or Lactic Acid.

A very palatable liquid is made by dissolving a dessert-spoonful of pure Citric Acid in a quart of water, and adding Glycerin to sweeten it according to taste.

Stimulants should be most sparingly used, and, when given, should consist of whiskey, brandy, or Hollands, or very bitter ale. Sweet wines are decidedly injurious.

The patient's hours should be very regular, and he should, as

far as possible, be saved from bodily fatigue, worry, or heavy brain work. Against changes of temperature he should be protected by being well clad in flannel, and should wear thick-soled boots. Gymnastic exercise may be advised, when weather and other contra-indications forbid exposure, but most authorities now lay stress upon the necessity of constant open-air exercise, and many recommend cycling and riding.

Before passing to the treatment by drugs, mention may be made of Donkin's method of treating diabetes by an exclusive diet of skimmed milk. About one gallon or more is the daily allowance. This treatment has met with pretty general condemnation. The writer has seen, however, excellent results in obese patients from an exclusive milk diet, and it is invaluable in albuminuric cases. Lépine advises that the milk be fermented.

In poor patients who turn up at hospital, and who may gain admission for a few weeks or even months, when they are compelled to leave and return to their homes, milk is really about the only available safe diet for them. Severe cases of diabetes will, unfortunately, be often found where milk acts most injuriously but fat patients sometimes do well upon it.

In agricultural districts, good buttermilk turned acid is a very valuable diet for the poor diabetic.

Too much cannot be expected from a pure dietetic treatment of the disease, and though, now and then, the physician may meet with a case where the sugar disappears entirely, nevertheless in young subjects especially, the sugar can sometimes be very little influenced by diet.

Landby places the patient upon a rigid diet for a week, and after determining the maximum of the effect produced by analysis of the total urine passed in 24 hours, he permits one large baked potato daily, and at the end of another week, if no increase in the amount of sugar be found, two potatoes daily are permitted. The principle being to allow the maximum amount of carbohydrates which the patient can assimilate.

There is no doubt that often harm is done by a too strict enforcement of a rigorous dietary, and the excessive use of animal food adds to the danger of acetonæmia.

In every case there are various drugs which may be employed with more or less benefit, though the drug which is to exert a specific action in diabetes has yet to be discovered.

Opium comes foremost amongst these. It can be tolerated in very large doses. The watery extract, in doses of $\frac{1}{2}$ gr. three times a day, may be started with, and the dose need not generally be pushed beyond three or four grs. Morphine may be employed in proportionately smaller doses.

Codaine is less likely to cause disturbance from its narcotic action, being a much weaker narcotic than morphine, and the good which opiates unquestionably accomplish in diabetes is altogether independent of their anodyne properties, and Bruce

has shown, when they are exercising their best effects in diabetes, that narcotic symptoms seldom are manifest. Fraser insists that codeine should simply be regarded as weak morphine. The dose of codeine may commence with $\frac{1}{2}$ gr., increased to 2 or 3 grs., three or four times a day. It will be found not to interfere with digestion, and is always well borne. Under its influence the amount of sugar generally markedly falls in a few days. Fraser found that the therapeutic value of 1 gr. morphine daily in diabetes exceeded that of 15 grs. codeine.

In cases where the codeine treatment with strict diet fails, any of the following drugs may be tried. The list might be much further lengthened out, as nearly every remedy has got a turn in the management of this serious ailment.

Antipyrine is placed next in value to opium and its alkaloids, and some observers go so far as to state that it possesses more influence over the diabetic process than these agents. It must be given in full doses, *i.e.*, 10 grs. 4 or 5 times a day, to be suspended as soon as any albuminuria appears.

Phenacetin, Antifebrin, Exalgine, and the other members of the same class, appear to have a similar but less certain effect.

Recently Ebstein has obtained marked results from Salol. As many as 60 grs. daily have been administered by Tesmacher.

Carlsbad Waters drunk freely at Carlsbad, in conjunction with strict dietetic treatment, till the urine becomes alkaline, with or without the opium or morphine treatment, have given satisfactory and lasting benefits in many cases.

The other natural alkaline waters in repute are:—Vichy, Neuenahr, Fels, Contrexeville, and Vals; and it is insisted by those at the places that the drinking of the waters at their source is much more efficacious than undergoing the treatment at home.

Alkalies have been much used, and the good effects of the Carlsbad water is doubtless owing to their presence. The waters of Vals and Vichy are, no doubt, of value in some cases. The alkaline carbonates and ammonia phosphate, the citrates of soda and potash and free ammonia, or its carbonate or acetate, have been pushed, but apparently with very little influence upon the amount of sugar. Alkalies and their carbonates are by Ebstein supposed to act by directly supplying carbonates and free carbonic acid to the protoplasm of cells throughout the body.

Saccharin has been vaunted as a cure. It is of use as a substitute for sugar, but here its therapeutic virtues end. Large quantities are liable to upset the stomach, and by leaving a permanent sweet taste in the mouth may destroy the appetite. Almost the same may be said of glycerin.

Permanganate of Potassium and Peroxide of Hydrogen have failed signally in the hands of most physicians, though the former is still recommended by Lépine.

Bromide and Salicylate of Soda, Cocaine, Picric Acid, Calcium Sulphide, Lactic Acid, large doses of Quinine, Ergot, Benzozol,

Camphor, Magnesium Salts, Lithia Salts, Creosote, and Arsenite of Bromine have been reported to have caused cures, but in other hands have almost always proved useless.

Jambul gave promising results. The dose is 3-5 grs. of the powdered seeds. Saundby and others, however, state that the drug is useless.

Rennet and Pepsin have been used and found wanting, and the same may be said of the plan of giving large doses of Yeast. Roberts has given Strychnine and Belladonna till their physiological effects have been evident without the least influence upon the sugar. Calabar Bean and Ozonic Ether have proved to be comparatively valueless. Sugar and Honey have been given with the idea of replacing the amount lost through the kidney, but with almost disastrous results.

Massage and Electricity, Quinine, Cod Liver Oil, Iron, and Laxatives of the Castor Oil or Cascara type, are generally useful in combating symptoms or complications arising during the disease.

Martineau's Specific, consisting of an aerated solution of Arsenate of Sodium and Carbonate of Lithium, has done some good as a nervine tonic and diuretic. Dujardin-Beaumetz spoke very highly of this treatment, which he modified in the following way—He gave 8 grs. of Carbonate of Lithium in a glassful of Vichy water, with 2 drops of Fowler's Solution, before each meal.

Oxygen, pumped into water and given as an aerated beverage, has proved beneficial in some cases.

Nitrate of Uranium, now recommended in much larger doses (10 grs. three daily), is still believed in by West.

Strontium Bromide has not proved of much value. The same may be said of Piperazine, Phosphorus, Iodoform, Ouabain, and Methylene Blue.

Powdered Eggshell, in tea-spoonful doses, is used at Neuenahr by Grube.

The above seems but a small portion of the list of drugs whose praises have been from time to time sung in the treatment of diabetes. It would appear that many observers, when getting a case of diabetes, place it at once upon a diet devoid of sugar and starch, and any drug which their fancy induces them to try they prescribe, and often fall into the error of ascribing all the good effects to it alone.

The complications arising during the disease are to be treated upon general principles.

Coma should be promptly met by large doses of free Alkalies, or the intra-venous injections of Bicarbonate of Soda Solution, or, better still, by large hypodermic doses of saline solution, as mentioned under Anæmia.

Keynolds lays great stress upon the necessity of very large doses of the Citrate of Potassium and great quantities of fluids to be swallowed by the mouth. Many cases are recorded where the

coma has disappeared after drachm doses every hour in large quantities of water.

As soon as the daily examination of the urine shows that the dietetic treatment has failed to make any further reduction of the daily excretion of sugar, or when the greatly reduced amount begins to remain at a standstill, then the opium treatment may be commenced. It is a mistake to do this without previously ascertaining the daily amount of sugar by Roberts' method.

The diet should be carefully regulated from day to day, and as much variety as possible afforded to the patient. Much will depend upon this, for if the patient be allowed to become disgusted by the sameness of his diet he is sure to suffer.

When the sugar has disappeared, a few ounces of bread may be tried, and if no sugar appears this may be gradually increased, but sugar should not be allowed, no matter how small the quantity.

Lépine's researches upon the part played by the pancreas in manufacturing a ferment which destroys the sugar in the blood have as yet not led to any therapeutic advance, though some authorities state that they have seen marked benefit follow the administration of zymme. Lépine has found benefit from the administration of a glycolytic ferment prepared from the diastase of malt, but the benefits are temporary.

The writer believes that he has seen unmistakable evidences of the value of Pancreatic Extract in keraline coated capsules.

Thyroid feeding, though recommended, has often done harm. Spermin is also vaunted.

Extract of Liver is recommended by Lamoreux, who gives it per rectum.

Saundby gives the following diet as containing 2,450 heat units with not more than 500 grs. sugar-forming carbo-hydrates—*i.e.*, 6 oz. cooked meat; 2 oz. fat bacon; 2 eggs; 2 oz. cream; 3 oz. butter; 3 oz. cheese; 6 oz. green vegetables; 9 oz. Callard's brown loaf, biscuits, and sponge cakes; $\frac{1}{2}$ pint bouillon; 1 pint tea; $\frac{1}{2}$ pint claret; 2 oz. Scotch whiskey.

The physician may find it advantageous to refer to the following diabetic dietaries, which are given in detail, along with much valuable practical information, in Yeo's book on "Food in Health and Disease."

PAVY'S DIETARY.

The following articles are allowed:—

Butchers' meat in every form except liver, bacon and ham, game, poultry; all kinds of fish, both fresh and cured, including the crustacea; animal soups (without thickening), including beef tea and broth.

Eggs, cheese, cream cheese, cream, and butter.

Almond, bran, or gluten substitutes for ordinary bread.

Greens, spinach, turnip-tops, watercress, mushrooms, mustard-and-cress, cucumber, lettuce, endive, radishes, and celery.

In moderate quantity, after boiling in much water, are allowed:—

Turnips, French beans, Brussels' sprouts, cabbage, cauliflower, broccoli, sea-kale, asparagus, vegetable-marrow; also pickles, olives, vinegar, and oil.

Jelly, flavoured but unsweetened, savoury jelly, blanc-mange made with cream and not milk, custard, made without sugar.

Nuts of all kinds except chestnuts.

Tea, coffee, cocoa from nibs.

Dry sherry, claret, hock, dry Sauterne, Chablis, Burgundy.

Brandy and spirits, unsweetened, soda water, Burton bitter ale in moderate quantity.

The following are forbidden :—

Sugar in any form, wheaten bread, and ordinary biscuits of all kinds.

Rice, arrowroot, sago, tapioca, macaroni, and vermicelli.

Potatoes, carrots, parsnips, beetroot, peas, and Spanish onions.

All kinds of pastry and puddings, and fresh or preserved fruits of all kinds.

Milk is forbidden except in very small quantity, and also port wine.

Sweet ales, mild and old porter and stout, cider, liqueurs, and all sweet and sparkling wines.

SIR WILLIAM ROBERTS' DIETARY.

The following articles are allowed :—

Butchers' meat, poultry, game, and fish.

Cheese, eggs, butter, fat, and oil.

Broths, soups, and jellies made without meal or sugar.

Cabbage, endive, spinach, broccoli, Brussels' sprouts, lettuce, spring onions, watercress, mustard-and-cress, and celery.

For bread is substituted—Bran cake, gluten bread (and meal), almond meal, rusks, and biscuits, also, "Torrified" or charred bread.

Dry sherry, claret, bitter ale, brandy and whiskey in small quantities.

Tea, coffee (without sugar), chocolate (made with gluten meal), soda water, bicarbonate of potash water.

The following are forbidden :—

All saccharine and farinaceous foods, bread, potatoes, rice, tapioca, sago, arrowroot, macaroni, etc.; turnips, carrots, parsnips, beans and peas.

Liver contains much sugar-forming substances, therefore, oysters, cockles, and mussels, which contain enormous livers, are forbidden; as is, also, the "padding" of crabs and lobsters.

All sweet fruits—as apples, pears, plums, gooseberries, currants, grapes, oranges, etc.

Port, and all sweet wines; sweet ales and porter; rum and sweetened gin.

EBSTEIN'S DIETARY.

For early breakfast he allows one cup of coffee or tea (black), without milk and sugar, white bread toasted, 30 to 50 grammes, or brown bread, well buttered, butter 20 to 30 grammes. The yolk of an egg, a little fat ham, or some German sausage (if required).

If any food be required between this meal and dinner, let it be a cup of broth with the yoke of an egg.

For dinner he allows—Broth, with yoke of egg or marrow (the marrow-bone is boiled for half an hour to solidify the marrow). Some peptone may be added to the broth.

Meat (180 grammes, free from bone), roasted, boiled, or stewed: beef, mutton, pork, veal, fowl, or venison (fat meat preferred). Gravies, with cream or yolk of egg, not flour. Or fish, with melted butter.

Vegetables, prepared with much fat; purees of leguminous plants. Salads, dressed with vinegar and oil, and some cream. The food should be well salted and spiced.

After dinner a cup of coffee or tea.

For supper are allowed one cup of tea or broth, meat roasted, ham or cheese, or an egg, or fish, caviare, bread (30 to 50 grammes) with butter (30 to 50 grammes). Apples, pears, and stone fruits are allowed in small quantities.

Beer is forbidden, and the use of spirits is limited. Half a bottle of wine daily is allowed. If the patient digests milk well, he is allowed it in moderate doses, and cream especially.

DÜRING'S DIETARY.

This dietary may be useful in some forms of glycosuria, but many of the substances permitted are positively injurious in most cases of diabetes.

Burney Yeo points out that this dietary differs from most others and is founded on the theory that the most important factor in the causation of diabetes is a faulty diet and disturbed digestion. Düring, therefore, insists only on a restricted diet, and the selection of the most digestive foods.

For early breakfast are allowed milk, with a little coffee, but no sugar (some lime water to prevent milk from becoming sour in the stomach); stale white bread *ad libitum*, or oatmeal, barley or rice gruel, made with water, a little salt, but no butter (if bread cannot be borne).

For second breakfast are allowed white bread, stale and well baked, an egg lightly boiled, rice or oatmeal gruel, with or without milk (a breakfast-cupful), or half a glass of good red wine (with water in certain cases).

For dinner (taken between two and three o'clock) are allowed soup with rice, barley, or oatmeal; meat, roast, 250 grammes (game, ham, and smoked meats, as free from fat as possible are permissible); no condiments, no fatty sauces.

Compôte of dried apples, plums, cherries, dried peas or white beans in some cases, green vegetables, asparagus, French beans, carrots, cauliflowers, cabbages (boiled in water with salt, not with fat or stock).

Dessert of a little raw fruit, apples, cherries, and one small glass of red wine, diluted with water.

For supper (about 7 p.m.) give gruel of barley, oatmeal, or rice, with salt (but no butter), and strained; in some cases may be made with milk ice or iced water, to relieve thirst between meals.

He lays great stress on the mode in which these vegetable foods are prepared, especially the cereals used for making gruel, and the legumes are, before being cooked, to be steeped for some time, and boiled long enough to make them more easily digested.

DIARRHŒA

Is but a symptom of various affections of a widely different nature, and the first duty of the physician before treatment is begun is to try and find out the cause of the condition. There can be no worse practice than to administer opiates in every case

of diarrhœa, or to follow the routine practice of pouring down trenches of chalk and catechu or other astringents. Severe and persisting diarrhœa may be produced by a mass of old feces lying in the large intestine, and in elderly people this cause should always be looked out for.

Most of the cases of acute diarrhœa met with in practice may be classed under the head of "Irritative." They follow some indiscretion in diet, and, especially in adults, may be safely regarded as if the patient had taken a cathartic which was irritating the small intestine, causing sometimes intense griping and smart purging. Such cases will require little treatment, and certainly should not be checked at first. The diarrhœa is nature's method of getting rid of a poison introduced from without in the food, or generated within the bowel, and if the physician must interfere, it may be best to assist nature, and give a mild dose (a drachm) of Castor Oil, or a tea-spoonful of Gregory's Powder. The severe pain is best combated by a large dose of Whiskey or Brandy, or 5 minims of Oil of Peppermint or other essential oil.

Salines, though often employed, are not, in the writer's opinion, suitable in these cases. They increase the pain, and, by rendering the motions quite fluid, may sweep past and not remove the source of irritation.

This form of diarrhœa is very common in infants fed upon cow's milk, and the early diagnosis of it will enable the physician to often save life. It can be recognised at once by an examination of the child's napkins, or by a description of them when not available for inspection. The motions consist of masses of indigested curd, closely resembling glacier's putty in appearance and consistence; these masses can be easily shaken off or detached from the napkin which they scarcely soil. They are often green in colour and are passed solid, with a little acid watery discharge often mistaken by the nurse for urine. Here the employment of vegetable astringents or opiates means delay, and too often death.

The first symptoms may be rapidly followed by vomiting, and if the cause be not promptly removed, a low and fatal form of enteritis sets in which is beyond the reach of drugs. The symptoms are so treacherous that before the physician is summoned this may already have taken place. The cow's milk should be instantly stopped, and a healthy wet nurse obtained. When this cannot be accomplished without delay, which is usually the case, two courses are open. Raw Meat, grated or pounded to pulp, may be given or made into strong beef tea; or Nestle's Milk Food should be tried. In emergencies of this kind, the writer is satisfied that there is no other food will give such good results. He has used it since its introduction into this country in 1873, and believes he has often seen it save life, which otherwise would have been lost. Excellent results are also obtained by Benger's Food. Directions must be given that no cow's milk

should be administered till long after the attack is passed, and then only in very small amount, and but once a day at first, watching its effects.

It is upon the whole better never to return to it if the attack has been a serious one. As soon as the child takes to the new food, a smart dose (one tea-spoonful) of Castor Oil should be given to clear any indigestible curds out of the bowel. No further drugs are needed in the majority of cases.

Meigs' Milk-and-Cream Food is an excellent diet, and when cow's milk must be returned to, it is the safest. A child 6 months old may have the following modified formula. The lime water may be replaced by Solution of Bicarbonate of Soda (3 grs. to 1 oz.) :—

Pure Fresh Milk, 3 parts ; Cream, $1\frac{1}{2}$ parts ; Lime Water, 1 part ; Sugar of Milk, $\frac{1}{2}$ part ; Boiled Water, 2 parts.

Tirard, in his excellent book on "Treatment" draws attention to the importance of warmth to the abdomen, and emphasises the value of an extra flannel binder.

Summer Diarrhœa is of a different nature altogether ; it is a form of irritative diarrhœa, occurring in infants or children a little older, but still very young. Here also the milk—generally cow's milk—is at fault, and there can be little doubt that the irritant is a microbe or ferment which secretes a highly poisonous principle, causing profuse and frequent liquid motions, so that severe cases are spoken of as Cholera Infantum.

It is unfortunate that these names are used in different senses by different writers, thus irritative diarrhœa is often called inflammatory. The irritative diarrhœa caused by curds of milk in infants is sometimes spoken of as "simple" diarrhœa, but if it passes on into entero-colitis it becomes an inflammatory diarrhœa.

The treatment must be the immediate withdrawal of the milk diet, and the copious administration of Ice or Iced Water with a purgative ; after which, Nestlé's Food, prepared fresh every time, or sterilized cow's milk may be given, provided it is clear that prior to the attack there was no evacuation of the firm, dry putty-like masses before described. Castor Oil is the safest purgative in these cases, the following old-fashioned combination is an excellent one, and a child one year old may get a powder twice a day :—

R. *Sodæ Bicarb.* gr. iv.
 Pulv. Rhei gr. iss.
 Pulv. Cinnamomi gr. i. *misce.*

Fiat Pulvis.

Sterilized milk is a safeguard against ordinary summer diarrhœa, or the more severe cholera infantum, which is probably caused by some pathogenic micro-organism.

It can be best sterilized by being heated upon a water-bath in small bottles for 15 minutes. The writer has long been in the habit of having all tubes and bottles soaked in a strong Solution of Boric Acid, and he advises a few grains to be added to each pint of milk as it comes fresh from the cow in summer weather.

There is no doubt that tubercular disease is communicated often through the milk of cows with tubercular deposits in the mammary gland and it is a wise measure to *always* sterilize the milk of bottle-fed children where there is any doubt about the purity of it, or of the health of the animal supplying it.

Bismuth, or Chalk Mixture, with occasional purgatives, the best of which is Castor Oil, is harmless. The following is a good routine formula after the diet has been made right; it may be freely given to a child 1 to 2 years old:—

R. *Bismuthi Carbonatis* gr. xlv.
 Tinctura Camphoræ Co. ʒj.
 Glycerini ʒss.
 Mucilaginis ʒss.
 Aquæ Chloroformi ad ʒijj. *misce.*

Fiat mistura. Signa—"A tea-spoonful to be administered after each loose motion."

This mixture may be used for a child 4 years old, by doubling the amount of Bismuth and trebling the Compound Tincture of Camphor.

Naphthaline has been used with much success on the Continent. The rationale being that it destroys, in the intestinal canal, the putrefactive or pathogenic micro-organisms which cause the diarrhoea, it also stops fermentation. It may be given in doses of $\frac{1}{2}$ to 2 grs. four times a day in sugar or wafer paper, to 2 year old children, and this dose may be increased to 5 grs. for children 6 or 8 years old, and has been found by Rosbach to be valuable in cholera infantum. Beta-Naphthol, now official, and the Alpha Salt are also useful.

Salol acts equally well. A child 6 months old may get 2 grs. three times a day.

Salicylate of Sodium, in slightly smaller doses, may be administered with half a minim of *Ol. Menthae Pip.* with the same objects in view.

Resorcin, Carbolic Acid, Creosote, Corrosive Sublimate, Bismal, Eucalyptus, Glycerin of Borax, Lactic Acid, and Iodoform have been successfully employed by different physicians, with the view of acting as intestinal disinfectants, instead of the old-fashioned and irrational method of pouring in opium, catechu, kino, logwood, roatan, acetate of lead, sulphate of copper or iron, and many other so-called astringents.

For the frequent, green, foul motions of inflammatory diarrhoea.

there is nothing better than 1 grain of Calomel given in doses of $\frac{1}{2}$ grain every hour, for six doses, to a child one year old.

The writer has had no experience of Illingworth's treatment, which is so favourably reported upon by many observers. It consists in the administration of $\frac{1}{16}$ grain doses of the Bimiodide of Mercury dissolved in Iodide of Potassium, and combined with doses of 1 grain of Chloral.

Irrigation, by inserting a soft rubber catheter into the stomach, and washing out till the tepid water used begins to return clear and sweet, and afterwards adding a trace of Corrosive Sublimate to the water, has been successfully employed. Opium, Chlorodyne, Chloral, Belladonna, Cannabis Indica, Chloroform, and Camphor may be given to relieve pain, check spasm, and diminish increased peristaltic action, in appropriate doses.

Where the seat of trouble is in the great intestine, disinfectants do not reach it, and then Babcock's plan of passing up a large, soft rubber catheter through the anus, and injecting large enemata of rather hot sterilized water, is an excellent one. Rice recommends Glycerin enemata, and various authorities resort to weak Corrosive Sublimate and other antiseptic injections.

Where the attack has lasted for a considerable time in the child or adult, the same treatment may be carried out, employing the drugs in larger quantity, and giving Opium more freely to relieve the increased peristalsis. Half drachm doses of Bismuth, with half drachm doses of the Pulv. Cretæ Arom. C. Opio, may be given to adults every 6 hours.

Compound Decoction of Aloes has a very striking effect in diarrhœa. It may, in one full dose (1 drachm to an infant, 1 $\frac{1}{2}$ oz. to an adult), cause a firm, natural motion where watery stools have been the rule for many days, and it can be administered safely in the worst cases, as a morning dose, when the ordinary astringent remedies are being administered during the day. The writer has obtained better results from this drug than from any other after the very acute symptoms have subsided.

Chronic diarrhœa may exist long after the irritants which caused it have been swept away. After free purgation by the Dec. Aloes Co., astringent tonics, as the Astringent Iron Salts, may be freely given after the diet has been carefully regulated. The Pil. Plumbi C. Opio may be given every 4 hours in doses of 3 grains. The Acetate of Lead may be given every 4 hours in doses of 2 $\frac{1}{2}$ grains, or $\frac{1}{2}$ grain of Copper Sulphate may be administered in pill. A favourite combination is the following:—

- R. *Tincturæ Calechu* ʒiv.
 Tincturæ Kino ʒiv.
 Tincturæ Opii ʒii.
 Spiritus Camphoræ ʒiij.
 Mistura Cretæ ad ʒvi. misc.

Fiat mistura. Signa—"Two tea-spoonfuls every four hours."

It can be best sterilized by being heated upon a water-bath in small bottles for 15 minutes. The writer has long been in the habit of having all tubes and bottles soaked in a strong Solution of Boric Acid, and he advises a few grains to be added to each pint of milk as it comes fresh from the cow in summer weather.

There is no doubt that tubercular disease is communicated often through the milk of cows with tubercular deposits in the mammary gland, and it is a wise measure to *always* sterilize the milk of bottle-fed children where there is any doubt about the purity of it, or of the health of the animal supplying it.

Bismuth, or Chalk Mixture, with occasional purgatives, the best of which is Castor Oil, is harmless. The following is a good routine formula after the diet has been made right; it may be freely given to a child 1 to 2 years old:—

R. *Bismuthi Carbonalis* gr. xlv.
Tinctura Camphoræ Co. ʒj.
Glycerini ʒss.
Mucilaginis ʒss.
Aquæ Chloroformi ad ʒij. misc.

Fiat mistura. Signa—"A tea-spoonful to be administered after each loose motion."

This mixture may be used for a child 4 years old, by doubling the amount of Bismuth and trebling the Compound Tincture of Camphor.

Naphthaline has been used with much success on the Continent. The rationale being that it destroys, in the intestinal canal, the putrefactive or pathogenic micro-organisms which cause the diarrhœa, it also stops fermentation. It may be given in doses of $\frac{1}{4}$ to 2 grs., four times a day in sugar or wafer paper, to 2 year old children, and this dose may be increased to 5 grs. for children 6 or 8 years old, and has been found by Rosshach to be valuable in cholera infantum. Beta-Naphthol, now official, and the Alpha Salt are also useful.

Salol acts equally well. A child 6 months old may get 2 grs. three times a day.

Salicylate of Sodium, in slightly smaller doses, may be administered with half a minim of Ol. Menthæ Pip. with the same objects in view.

Resorcin, Carbolic Acid, Creosote, Corrosive Sublimate, Bismal, Eucalyptus, Glycerin of Borax, Lactic Acid, and Iodoform have been successfully employed by different physicians, with the view of acting as intestinal disinfectants, instead of the old-fashioned and irrational method of pouring in opium, catechu kino, logwood, rhubarb, acetate of lead, sulphate of copper or iron, and many other so-called astringents.

For the frequent, green, foul motions of inflammatory diarrhœa

the tincture twice a day is the most agreeable method of using the drug.

Pepsin and peptonised foods are most valuable in the chronic diarrhœa of children.

Coto Bark, 5 grains, Cotoin, $\frac{1}{2}$ gr. every 4 hours, are valuable in diarrhœas of phthisis and chronic intestinal catarrh.

Enemata containing many of the above may be used with a little Laudanum and Starch. The plan of washing out the colon with astringent and disinfecting solutions and Nitrate of Silver injections may be resorted to when the mischief is clearly a large intestine affair.

Quinine in large doses (to grs.) affords the best method of treating vicarious diarrhœa where it is safe to interfere. In uræmic diarrhœa, diaphoretics and diuretics are indicated.

Digitals and Caffeine are the best remedies where the diarrhœa is depending upon congestion of the portal system caused by cardiac embarrassment and failure.

Raw Meat and Beef Juice are very useful adjuncts. Niemeyer and Trousseau used the former in the chronic diarrhœa of teething infants with great benefit.

Arrowroot, or the old flour ball made by boiling common wheat flour in a bag for many hours until it becomes hard and then grating it, is recommended by A. V. Meigs in infantile diarrhœa.

For the treatment of the diarrhœa occurring in affections of the colon see Colitis. See also under Typhoid Fever, Dysentery, &c.

DIPHTHERIA.

Before mentioning the new antitoxin treatment, it is advisable to describe the general management of the disease.

Diet is of the most vital importance, and there are few diseases in which feeding should be so closely looked after as in diphtheria, though Weber affirms that sudden collapse is not prevented by over-feeding. Cormack insisted upon the uselessness of feeding unless Pepsin was added to the food. This is true only of the later stages of the affection, and must be kept in mind.

Strong stimulating food in large amounts, and in as short intervals as possible, should be the rule, so as to maintain the patient's strength. He should be kept in bed with light though warm clothing, his 'body heat' must be anxiously watched, especially in the later stages of the disease, and signs of coldness of the extremities must be met with prompt applications of local warmth.

Stimulants should not be commenced too early, and in very mild cases may not be required at all, but generally stimulants will be found necessary and if the physician can manage successfully to blend food and stimulant together it will be well, as food, stimulant, and medicine follow each other so closely, more time for feeding may be thus obtained. The best arrangement is to

give brandy or whiskey with the milk, or good old port with beef tea or sherry made into wine whey. Strong soups (oyster, turtle, or hare), beef jellies, good beef tea, or beef juice, or chicken soup peptonised, or paste made of pounded beef to which a few grains of pepsin are added, may be given at short intervals. If the disease progresses and emaciation occurs notwithstanding the consumption of a large amount of nourishment, and there appears a fair amount of albumin in the urine, it will become evident that the patient cannot long stand the siege unless the digestion be improved. Everything in the way of food must be peptonised, and enemata of peptonised food must be given at shortest possible intervals.

If the larynx is involved in the disease, the steaming, heating, and ventilating of the room as detailed under Croup must be carried out. In every case, ventilation and a generous supply of fresh, warm air must be kept up. Considering the highly infectious and serious nature of the disease, it will be the duty of the physician to direct measures for the prevention of the spread of the disorder to the other inmates of the house. The sick-room, placed if possible under a trained nurse, must be isolated, and all articles or persons leaving it must be regarded as possible conveyers of contagion. It is a good plan to have a large pail of water to which a liberal amount of Condys' Fluid has been added; this should be placed outside the door of the room, and with it all spoons, knives, forks, plates, cups, &c., should be dropped as they leave the hands of the nurse. As a probable source of the original virus, house drains the water and milk supplies should be looked into, and the part that living poultry (chickens and turkeys) play in causing the disease in man should not be forgotten. The disease has been spread by calves and cats, and the writer has known of a case where a fatal form of the disease was caught from a donkey.

The value of the diphtheritic antitoxin as a preventive or immunising agent will be referred to presently.

The local treatment of the disease has been placed upon a sounder basis since the pathology of the affection has been accepted to be the presence of the *K. Loeffler* bacillus which flourishes in the false membrane, and produces poisons which on being absorbed cause the constitutional effects of the disease.

It would appear at first sight that the main indication in the treatment of diphtheria would be to get at the false membrane as soon as possible and effect its destruction, but the *Klebs Loeffler* bacillus, which produces the membrane, is to be found only in its growing, active condition in the middle layers toward the surface, but not upon the surface where it can be reached by germ destroyers. This fact explains many of the difficulties and mysteries in connection with the failure of the various plans of local treatment in the disease. The physician who keeps painting the surface of the false membrane is simply bringing his remedies

or agents into contact with bacilli, the majority of which have already become innocuous.

Of local methods of treatment there is practically no end, but their use is largely neglected since the success of the serum treatment has become universally recognised.

Caustics are now seldom applied.

Strong Solution of Perchloride of Iron, Carbolic, strong Lactic, and other Acids are, or have been, freely used to cauterise the local seat of the disease, but it appears to be demonstrated that any substance which acts as a *caustic* and destroys the tissues must increase the mischief, the bacilli rapidly developing wherever injury to healthy tissue has taken place. Where good results have followed caustics it is in all probability because these agents have failed to act as caustics, but have become efficient *antiseptics*.

Of antiseptics, the best and most reliable is Perchloride of Mercury, and, as pointed out by Yeo, it is too often used in such a state of dilution as to be useless. Le Gendre swabs the patches with lint, *moistened*, but not dripping, with a 1 per cent. solution in alcohol every 6 or 8 hours. Next in value to this powerful germicide is a freshly prepared 10 volume (or 3 per cent.) Solution of Peroxide of Hydrogen, used as a swab or spray.

It is generally held that no attempt should be made to forcibly peel off or tear the membrane from the underlying mucous surface, though some insist upon this, and brushes have been devised for its forcible removal. Attempts have been made to cause the disintegration of the membrane by acting upon it with agents which have the power of digesting animal substances. Pepsin and Papain, or the raw juice—Papayolin—from which the Papain is derived, have been applied with what some authorities regard as brilliant successes. In the hands of others they have led to dismal failures. Finkler's Papain, dusted as a powder over the surface of the membrane, when reachable, is free from objection, and further trials may show its value, especially when we consider that anything which would break up, digest, or disintegrate the false membrane, would then permit of antiseptics being brought into contact with its deeper layers where the bacilli are growing actively.

Another class of remedies has been employed to cause solution of the membrane. Foremost amongst these come dilute Solutions of Lactic Acid and Lime Water, used as gargles or sprays. The Lactic Acid (5 per cent.) may be freely used, 1 part to 8 or 10 of Lime Water may be also tried, both as gargle and spray, and locally applied with a large soft camel's hair brush. There is no doubt that these substances possess considerable power of dissolving the false membrane. The fumes of Hydrofluoric Acid, given off when fluor-spar is acted upon by heated Sulphuric Acid in a leaden vessel, also possesses this power.

Whatever difference of opinion may exist about the utility of these various methods of local treatment, there is an overwhelming

mass of testimony in favour of repeated applications of mild antiseptic solutions. The writer has also satisfied himself of their great value, if not in cutting short the disease, certainly in minimising the risk of septicæmia, and in controlling suppuration and putrefaction in the neighbourhood of the membranous exudations.

One of the least objectionable and most innocent of these remedies, and one which may safely be entrusted into the hands of the nurse even when very young children and infants are to be dealt with, is Boracic Acid. A saturated solution of the acid in Glycerin may be freely applied with a soft brush every hour or oftener where there is much fetor. A solution of 3 drs. in 20 oz. water may be used as a spray or gargle as often as possible without causing worry and annoyance.

Corrosive Sublimate, as just mentioned, is strongly advocated as a powerful antiseptic in 1 per cent. solution, when applied to the patch of false membrane. A spray of 1 gr. to 8 oz. may be very frequently and safely used. Some authorities remove the false membrane by a brush and then apply a 1 in 500 solution. Loeffler, who has studied the action of the various germ destroyers upon artificial cultivations, finds this agent to be the most powerful of the series. Next to it he finds a 3 per cent. alcoholic solution of Carbolic Acid (i.e., 3 drachms in 12 oz.).

Carbolic Acid, 1 drachm in 10 oz. rose water, is a safe, valuable, and elegant spray solution; to it may be added Boracic Acid, 1 to 2 drs., with advantage.

Chlorinated Soda Solution, diluted with 20 times its bulk of distilled water, or Solution of Chlorine, mixed with 30 times its volume of water, may be used with advantage where there is much fetor. Chlorinated Lime may be used in the same way. Chlorate of Potash, 5 grs. to 1 oz. water, with or without as much Chloride of Sodium, is a favourite gargle or spray solution.

Solution of Perochloride of Iron, 1 part of the strong liquor to 4 of water and 2 of Glycerin, may be applied with a brush.

Permanganate of Potash, 6 grs. in 20 oz. water, may be used as an injection where the nostrils are involved.

Chloral Hydrate, 1 drachm dissolved in 1 oz. Glycerin, may be brushed on; or a solution, 10 grs. to 1 oz. water, can be used as a spray or gargle.

Oil of Peppermint (undiluted) may be freely applied with a brush.

Salicylate of Soda, Sulphates, Sulphocarbolates, Sulphurous Acid, Tannin, Quinine, Chinolin, Iodine, Resorcin, Iodoform, Creolin, and nearly all the newer antiseptics, have been employed in much the same manner, either as a spray, gargle, injection, or in stronger solution for brushing over the membrane. The popular remedy, Sulphur, should not be omitted. It is used as a gargle, $\frac{1}{2}$ oz. to the pint, and the powder is used as an insufflation, or dusted on with a dry brush, alone, or mixed with Quinine. Sulphur certainly may prove very efficacious; the sulphuretted hydrogen which is given off after its contact with the organic matter acts as a powerful

germicide. Vlemingh's Solution has been used by some practitioners; it is more active than Sulphur.

Dr Martin has published excellent results obtained by the insufflation of Sulphate of Magnesium.

Various inhalations have been employed. They are of great value as adjuncts to the more direct treatment, and may be the only available means of reaching the disease locally in cross and nervous children, who repel all attempts at spraying or brushing out the throat.

Oils of Turpentine and Eucalyptus, Terebene, Tar, &c., may be made to saturate the atmosphere of the sick room by mixing them with boiling water or steam. Iodine and Bromine may be also used in this way.

Where diphtheria extends to the larynx or trachea, or where it has started from or remains confined to these regions, its treatment may be carried out exactly on the same lines as laid down for the management of true croup. (See Croup.)

The question of Tracheotomy and Intubation is discussed under the head of Croup, upon page 187.

In the later stages of nearly all severe cases of diphtheria constant irrigation of the nasal cavities and the back of the pharynx by the nasal douche or by a syringe is of vital importance. A warm stream of any weak, unirritating antiseptic solution may be employed every hour, in order to remove all pus or decomposing secretions. The plan of forcible irrigation as a routine method in all cases of the disease is a mistake; it causes so much excitement in young children that the subsequent exhaustion may be very serious.

Internal or constitutional treatment.—Behring discovered that when a guinea pig was artificially rendered immune to diphtheria, its serum prevented the diphtheritic poison from killing another animal if injected a little before, at the same time or soon after the injection of the poison prepared from pure cultures of the Klebs-Loeffler bacillus. This discovery has opened up one of the most satisfactory fields of research in therapeutics.

The following is the most generally accepted working hypothesis for explaining these results.—When the poison of diphtheria gains admission to the blood of a patient suffering from the growth of a false membrane upon his air passages, it is met by an antagonistic substance which acts as an antidote to it, and in favourable conditions completely neutralises its poisonous properties. This substance, now known as Antitoxin, either already exists in the blood or tissues, or is rapidly manufactured by them under the stimulus of the diphtheritic poison. If there be enough of it in the blood the patient recovers; if not, the poison exerts its lethal action upon the system, and death ensues. As the outcome of many experiments, it was found that the horse and goat were naturally immune, or almost so, and their serum had to a certain degree the power of antagonising the diphtheritic poison.

or toxin when injected into man and other animals. It was found that by rendering these animals (the horse and goat) entirely immune a much more valuable serum or antitoxin could be obtained. The horse, for many reasons, was found to offer the best results, and the plan generally followed is to inject increasing doses of the diphtheritic poison (toxin) into the tissues under the skin. The animal shows practically no signs of illness or constitutional disturbance, and it is found that his blood or tissue soon manufactures large amounts of antitoxin, so that the protective value of serum drawn from his vessels increases greatly after the injections. At the end of about six weeks, when the animal has been receiving about 100 cubic centimetres of a *filtered* culture of the diphtheritic bacillus, he is bled from the jugular vein, and after the blood has coagulated, and the serum quite separated, the latter, under antiseptic precautions, is preserved in sterilised bottles for use.

Before being used its antitoxic strength must be determined. This is done by mixing it with known quantities of the diphtheritic toxin, and injecting it under the skin of the guinea pig, and it is easy in this way to determine approximately the dose for a human being. It must, however, always be remembered that as regards dosage everything depends, as shown by Kuffer, upon the interval elapsing between the introduction of the toxin and the antitoxin; thus, in the case of guinea pigs, which are very susceptible, a dose of the antitoxin, which, if injected at the same time as the toxin, would completely antagonise its action, would be useless if injected an hour later. When 11 hours elapse after the introduction of the toxin, a dose 5,000 times greater is required. This shows how important it is that no time should be lost in injecting the antitoxin as soon as the disease is observed by the physician. If the experimenter waits too long before injecting the antitoxin the remedy fails entirely, even in enormous doses, and hence Kuffer explains its failure in the human subject when its injection is delayed too long. The dose is now fixed not by measure but by the number of immunisation units; thus, an initial dose of 1,000 or 1,500 units may be given to a very young child on first coming under observation, and this may be repeated in 12 hours. Where the case is not seen till the disease has got several days' start, 4,000 units may be given to a 5 year old child. 8,000 to 12,000 units may be given in severe cases when first seen, and this dose may be repeated in 12 hours, and again in 12 hours. Apparently hopeless cases have yielded only after 20,000 units administered during 36 or 48 hours. The injection is made in any convenient locality with a large sterilised hypodermic syringe under strict antiseptic precautions. The subcutaneous tissue of the flank or back is generally selected, and no local trouble should ever follow.

There is occasionally a slight increase of temperature or evidence of reaction after the injection, soon followed by a steady decline

in the original fever. The membrane speedily ceases to grow, and rapidly disappears, and the constitutional symptoms begin to improve sometimes in a few hours after the injection. The results of many thousands of injections have demonstrated that the antitoxin is harmless. It is difficult to give even an approximate calculation of the mortality of diphtheria after treatment by this agent, as cases and epidemics of the disease vary so widely, but from a perusal of reports from all parts of the world during late years, it is safe to conclude that the introduction of the antitoxin has reduced the mortality of diphtheria to less than half what it was a few years ago. Rosenthal publishes some striking figures obtained from the official records in 157 American cities. In 183,256 cases treated before the serum period the mortality was 38·4 per cent. In 132,548 cases treated since, the death rate was 14·6 per cent., but as many of these did not get any serum treatment, this percentage does not represent the saving of life by serumtherapy. The mortality of all these cases which were treated with serum was only 9·8 per cent., thus showing that the mortality was four times as great under the old methods. Munn's Denver statistics also prove that four times as many cases died when antitoxin was omitted from the treatment as when it was used. Another important point is that it appears to be demonstrated that the remedy has decidedly *preventive* action, and upon an outbreak of the disease those exposed to its influence may be protected by injections.

It is, however, unfortunately evident that the period during which a protected person is immune is a short one, and this fact diminishes considerably the value of the serum as a protective agent. Klein has shown by direct experiment that its *immunising* power is not in proportion to its *curative* value. If the horse from which the serum is obtained has been rendered immune by injections of living cultures of the bacilli of diphtheria, the result is that its immunising power is much greater than if the animal had been immunised by injections of the *filtered toxin* as in the preparation of the more highly antitoxic serum of Behring and Roux. It thus appears highly probable that the antitoxin and the immunising constituents of the serum are different substances, and he thinks that it may in future be possible to combine both processes in the immunisation of animals used for the production of serum.

The introduction of serum dried *in vacuo*, the product being in the form of golden scales readily soluble in water, and which keep unaltered for indefinite periods, is sometimes a great convenience. One great advantage which this dried material possesses over the ordinary serum is that cutaneous rashes do not follow its administration. All those who have had extensive opportunities of trying the serum treatment of diphtheria are convinced of its great value, but some point out the importance of not expecting too much from it. Thus the percentage of

cases of paralysis has not diminished under its use, but this is probably owing to the fact that this sequel is more common after severe attacks, and as many of these patients are saved by the serum it may be expected that paralysis will be more commonly noticed. The agent is practically, if not entirely, harmless, and since its value is so absolutely demonstrated it should always be administered in all cases; even moribund cases should have the advantage of the slight hope which its use justifies. A very encouraging feature in the results is the diminished mortality in tracheotomy cases, and several observers have reported that operative interference was much less frequently needed, and some affirm that the treatment enabled them to perform intubation where tracheotomy would otherwise have been inevitable. Prof. Ranke of Munich reports that his mortality has fallen from 57 to less than 18 per cent., and he states — "What seems to me to prove the value of the serum treatment even more than these figures is the change in the clinical features of the disease—under its influence diphtheria loses its progressive character. Amongst all my cases I have not had a single one in which laryngostenosis developed itself after injection if symptoms of it had not been present already on admission."

The use of the antitoxin need not and should not interfere with the exhibition of internal agents which past experience has proved to be of value in the treatment of diphtheria. Chief amongst the best tried remedies is Iron, which should be given in large doses; 20-30 minims of the tincture well diluted may be given every four hours. If there be much feverishness or a dry skin the following is a good routine recipe for an adult —

R. *Tincturæ Ferri Perchlor.* ℥j
 Liquor. Ammoniac Acet. ℥iij.
 Glycerini ℥i.
 Aquæ ad ℥xij. misce.

Ft. mist. cujus capiat ℥ss. ex ℥i. *aquæ quartâ quâque horâ.*

A child one year old may get a tea-spoonful of the above.

Many substances have been recommended upon the antiseptic or anti-microbic theory, with a view of destroying in the system the micro-organism which was supposed to be the cause of the disease. These are mainly discredited since the discovery that the symptoms of diphtheria are caused by the toxins which enter the blood, the microbes remaining generally at the local seat of the disease. Nearly every known antiseptic substance has been administered by the mouth, but with, upon the whole, not very satisfactory results. The following have been tried:—Bichloride of Mercury or the Red Iodide of Mercury, in doses of $\frac{1}{4}$ grain, every 3 or 4 hours. (Jacobi gives to a child 4 years old $\frac{1}{2}$ grain of

the Bichloride in 24 hours for 1 week, diluted in 1 to 6,000 or 1 in 10,000 in milk or water) Calomel in 1 grain doses, and the Cyanide $\frac{1}{2}$ gr., are advocated.

Boric Acid is given in 15 grain doses, every 4 hours, and Borax in similar doses. Either of these drugs may be mixed with the milk. Noel believes that they are eliminated by the mucous glands of the throat and mouth, and act locally upon the disease.

Oil of Turpentine, 3 capsules of 10 minims each, may be given every 3 or 4 hours, or the oil may be given in emulsion.

Eucalyptus and Creosote have been given in smaller doses. They are supposed to act in a similar way.

Peroxide of Hydrogen has been given internally in drachm doses.

Salicin, Salicylic Acid, or the Soda Salt has been given alone, and in conjunction with the Turpentine treatment, with what appears to be success.

Sulphur internally has been extolled, and it differs from most of the previously-mentioned remedies in being perfectly harmless. Knaggs, after many trials, found that it could be best administered in Glycerin, which he "believes greatly enhances the efficacy of the sulphur." He gives 1 to 2 tea-spoonful doses of a mixture of 3 drs. pure precipitated Sulphur, rubbed up with 2 drs. Chocolate Powder in 6 oz. Glycerin, flavoured with a little Cinnamon. The writer finds that the best method of prescribing Sulphur is to mix it with Orange Marmalade.

Benzoic Acid or Benzoate of Soda, in large doses, has many advocates. $\frac{1}{2}$ drachm of the Soda Salt may be given.

Chlorate of Potassium—10 grs. in water every 3 hours. This is anything but a safe treatment, and the writer believes that its administration in scarlatina and diphtheria raises the death rate by its irritant action on the kidney.

Sulphocarbates—10 grs. in water 4 times a day. Sulphurous Acid—in doses of 30 to 60 minims, well diluted.

Guaiacum—30 to 60 minim doses of the Ammoniated Tincture in Sherry.

Liquor Potassæ—30 to 45 minim doses, well diluted.

Sodium Hyposulphite, and Sulphites—in 20 gr doses in water.

Calcium Sulphide— $\frac{1}{2}$ gr. in pill every hour or two hours.

Solution of Chlorine—15 minims, well diluted, every hour.

The above list is but a sample of the host of agents vaunted in the cure of this formidable disease. The writer, before the introduction of Antitoxin, had ceased to believe in any drug but Iron, and, combined with the new treatment, he believes it will always hold its place.

For cardiac failure in addition to stimulants and feeding, there is no drug to be relied upon but Strychnine, and it must be given in large doses hypodermically in the presence of grave collapse. Digitalis may be combined with it. Absolute rest, if possible, and the avoidance of all sudden changes of posture should be

mosted upon in most cases, and especially where there is evidence of cardiac weakness.

Diphtheria of wounds is best treated by sprinkling Calomel over them, or applying a strong caustic, as solid Nitrate of Silver, Chloride of Zinc, or pure Lactic Acid.

Diphtheritic paralysis is best treated by forced feeding or rectal alimentation, full doses of Iron, Quinine, and Strychnine, and the continuous and interrupted current in conjunction with massage and constitutional remedies calculated to assist the general nutrition, as Cod Liver Oil, change to the sea-side, &c. For further details see under Paralysis (Diphtheritic).

DISLOCATIONS.

The first indication for treatment in a case of dislocation is the obvious one of taking speedy measures for the restoration of the bone to its normal anatomical position.

If the displacement be seen *immediately* after its occurrence, in most cases it can be easily rectified by manipulation, as the great obstacle to reduction is not present to any extent. Thus is the reflex muscular contraction which offers such marked resistance to the efforts of the surgeon.

As is nearly always the case, some time has elapsed between the receipt of the injury and the visit of the surgeon, and then this reflex muscular contraction has developed.

Formerly force was the remedy always used for overcoming this, but the use of the general anæsthetics—Chloroform and Ether—has almost relegated the pulley, cord, and weights to the museums of surgical antiquities. Nevertheless force, when judiciously applied will always continue to be a valuable aid in some cases. The aim of the surgeon should be to replace the bone by manipulation when possible; as a rule this is easy when the patient has been thoroughly chloroformed.

By movements of flexion, extension, adduction, abduction, or circumduction, the bone is replaced noiselessly in its capsule, the exact nature and degree of movement being determined by various factors, such as the formation of the joint, the extent of the rent in its capsule, the displacement of tendons &c. Sometimes when complete narcosis has taken place the bone may be, as in shoulder dislocation, easily replaced in its socket by the direct pressure of the fingers upon its articular extremity.

When chloroform or ether is not available, or is contra-indicated, steady traction is to be made in the direction of the new axis of the limb till the resistance of the muscles is almost completely overcome, when the bone may be felt to slip into its place with a snap, being replaced by the action of its own muscles, as is witnessed in the reduction of dislocations of the humerus by placing the heel in the axilla, and making steady forcible traction upon the limb. Often patient and gentle manipulation will achieve this without any appreciable degree of force being employed, and

the writer, when resident surgeon in a large hospital for two years, nearly always reduced shoulder dislocations without chloroform in this way by raising the arm upwards, the bone being manipulated into its socket at a moment when the muscles were taken unawares, or during a brief period of relaxation or exhaustion. Dislocations of the hip in nearly all recent cases can be reduced by manipulation under chloroform. The surgeon uses the femur as a lever to replace the head through the torn capsule by executing the movements of flexion, rotation, abduction, or adduction, according to the position of the displaced bone.

In old-standing dislocations considerable force must be used, but even then pulleys are seldom required. It becomes a serious question to determine the limit of time since dislocation, which should prohibit some attempt being made to replace the bone. The humerus has been replaced after six months, and in one case after the lapse of one year. The hip has been reduced in several cases after six months, but many instances are on record where death from rupture of arteries has supervened upon attempts at reduction in long-standing dislocations.

Space does not permit of a detail of the various manipulations necessary for the reductions of the numerous dislocations occurring in the body.

After the bone has been replaced an ice bag or evaporating lotion should be applied to the joint. The mistake most generally made is to keep the joint too long at rest. Gentle movements should be commenced early, not later than one week, and the absorption of effused products promoted by massage. This is especially necessary in the elbows of children, and excessive care has been responsible for numberless ankylosed elbows.

Bennet argues the use of massage after the first day, with a view of preventing muscular wasting, which he says is the chief cause of recurrent dislocations.

DROPSY.

The treatment of this symptom or sign will be mentioned under the heads of the different diseased conditions which are the causes of the accumulation of serous fluid. Thus the treatment of general dropsy is referred to under Bright's Disease and Heart Affections, and dropsy of the peritoneum under Ascites.

DROWNING.

After the patient has been rescued from the water he should be turned upon his face for a second or two to permit the escape of any fluid. At the same time firm pressure should be made over the abdomen and thoracic margin. The following rules are recommended by the Royal Humane Society; they were drawn out originally by Sylvester

"Rule 1.—To maintain a free entrance of air into the wind-pipe, — Cleanse the mouth and nostrils, open the mouth; draw forward

the patient's tongue and keep it forward; an elastic band over the tongue and under the chin will answer this purpose. Remove all tight clothing from about the neck and chest. See that nothing is lodged in the larynx, pharynx, or oesophagus.

"Rule 2.—*To adjust the patient's position.*—Place the patient on his back on a flat surface inclined a little from the feet upwards; raise and support the head and shoulders on a small, firm cushion, or folded article of dress placed under the shoulder-blades. If natural respiration has ceased, instantly proceed to carry out

"Rule 3.—*To imitate the movements of breathing.*—Grasp the patient's arm just above the elbows and draw the arms gently and steadily upwards until they meet above the head (this is for the purpose of drawing air into the lungs); keep the arms in that position for two seconds; then turn down the patient's arms and press gently and firmly for two seconds against the sides of the chest (this is with the object of pressing air out of the lungs). Pressure on the breast bone will aid this.

"Repeat these measures alternately, deliberately and perseveringly, fifteen times in a minute, until a spontaneous effort to respire is perceived, immediately upon which cease to imitate the movements of breathing, and proceed to induce circulation and warmth (Rule 5).

Should a warm bath be procurable the body may be placed in it up to the neck, continuing to imitate the movements of breathing. Raise the body in twenty seconds into a sitting position, and dash cold water against the chest and face and pass ammonia under the nose. The patient should not be kept in the warm bath longer than five or six minutes.

"Rule 4.—*To excite inspiration.*—During the employment of the above method excite the nostrils with snuff or smelling-salts, or tickle the throat with a feather. Rub the chest and face briskly, and dash cold and hot water alternately on them. After natural breathing has been restored proceed to carry out

"Rule 5.—*To induce circulation and warmth.*—Wrap the patient in dry blankets and commence rubbing the limbs upwards firmly and energetically. Friction must be continued under blankets or over dry clothing.

"Promote the warmth of the body by the application of hot flannels, bottles or bladders of hot water, hot bricks, &c., to the pit of the stomach, armpits, between the thighs, and to the soles of the feet. Warm clothing may generally be obtained from the bystanders. A tea-spoonful of warm water, wine, warm brandy and water or coffee may be given as soon as the power of swallowing has returned. The patient should be kept in bed and sleep encouraged.

"During reaction large mustard plasters to the chest and below the shoulders will relieve the distressed breathing.

The above method of performing artificial respiration is known as Sylvester's. If the stomach should be full of water, pressure

made upon it may force the water up the gullet during the expiratory manœuvre, and this water may be sucked into the trachea and bronchi during the artificial inspiratory act.

Marshal Hall's ready method is sometimes useful in the absence of all assistance. It is carried out by placing the body first on the left side and rolling it over with the face downwards, so as to drive the air out of the lungs, and then rolling it back again till the face looks upwards and the dorsum is in contact with the ground, when the elastic recoil of the ribs will draw the air into the lungs. These alternating rolling movements should be performed about twelve times in the minute.

Howard's treatment consists in first turning the patient upon his face, with his forehead resting upon his wrist or forearm to keep the mouth from the ground. A firm roll of clothing is placed under the stomach, so as to cause the head to be considerably lower than the trunk. By pressing forcibly and firmly upon the spine, water is thus forced out of both stomach and lungs. The body is then rapidly turned over face uppermost, with the roll of clothing beneath the thorax, and the head and neck bent well backwards, and the arms held above the head by an assistant, who should also keep the tongue well forwards. The operator, kneeling astride the patient's hips, places the palms of his hands upon the thorax over the short ribs, with the tip of each thumb upon the xiphoid cartilage. Then by alternately throwing the weight of his body forwards for two or three seconds and suddenly easing off with a push and resting for three seconds, the air is made to leave and to enter the thoracic cavity at about the rate of ten times in a minute.

Laborde's method of seizing the tongue and making forcible rhythmical tractions upon it 12 to 15 times in one minute has saved life after failure of the above plans.

The induced current may be used by applying one pole over the phrenic nerve in the neck and the other over the sixth interspace between the right axillary and mamillary lines, so as to produce vigorous contraction of the diaphragm. The poles should be applied at the moment when the artificial inspiratory manœuvre is being performed.

The efforts at restoration should be continued for at least half an hour, and if there be the slightest sign of returning life at the expiration of this time, the operator should not cease for one hour longer at least. Hypodermic injections of Ammonia and Ether may be given after breathing is established.

Two minutes' submersion is held to be fatal. The writer has timed, at a private *seance*, a professional swimmer who remained under water in a large glass tank 4 minutes 5½ seconds, his features being under observation all the time. The performer was slightly exhausted, but in a minute afterwards appeared perfectly well. (See also Asphyxia.)

DUPUYTREN'S CONTRACTION OF THE PALMAR FASCIA

Can only be successfully treated by a free division of the contracted and thickened bands of palmar fascia with their prolongations. In mild cases at the beginning forced extension by elastic tractors and bandaging upon a splint applied to the palm of the hand at night, with passive motion assiduously kept up during the day, may effect a cure. The writer has seen one case, where the little finger was affected, yield to this treatment, but, as a rule, the contraction steadily progresses.

The free subcutaneous division of all the bands by a stout tenotomy knife, and the application of an inflexible splint extending from the middle of the forearm beyond the tips of the fingers, is the simplest method of dealing with this troublesome affection. If the contraction returns after this treatment there is nothing left but to dissect a flap of skin from the palm of the hand and divide each band of thickened fascia, continuing the dissection till the fibrous prolongations extending into the web of the fingers are completely excised, care being taken not to interfere with or open the sheaths of the flexor tendons. Kocher insists upon thorough *excision* of the thickened and shortened palmar fascia with its extensions, after simple longitudinal incision of the skin of the palm and this is the most satisfactory and efficient of all methods. He holds that no operation can guarantee against relapse unless it include prophylactic excision of healthy parts of the fascia.

There is still considerable difference of opinion amongst surgeons regarding the relative values of the subcutaneous and open operations. Adams operated by the subcutaneous method. Thus plan, though it does not admit of excision of the fascia, or the remedying of the gouty deformity of the joints, or of the division of the bands when they have become calcareous, nevertheless admits of repetition in cases of relapse, which is a great advantage over the open operation, as in many cases where this fails the relapse is incurable.

DYSENTERY.

For the epidemic form of the disease which is generally restricted to the colder temperate regions, and for the endemic form which commonly confines itself to the hotter parts of the globe, the treatment is practically the same. (Amibic dysentery will be referred to later on.) The patient should at once be ordered to bed, and a milk diet alone, or combined with strong soups or meat juice, is the best. Where milk can be freely taken it is all that is necessary in most cases, and solids in any form are to be prohibited as in typhoid fever.

Ipecacuanha affords the best chance in the great majority of cases. 30 grs. of the powdered root should be administered as soon as possible in water paper, and repeated every 8 or 10

hours till the motions begin to show some signs of an approach to their natural character. The testimony of many observers goes to show that with a little care vomiting seldom occurs. Should nausea supervene, a sinapism over the abdomen, a little ice by the mouth, and a small dose of Opium before the next dose of the remedy meet the situation.

Some recommend small and oft-repeated doses of say 5 grs., others give 60 to 90 grs. in one dose at the beginning, repeated in 12 hours again, when frequently all tenesmus and diarrhoea cease. Agents like Salicylate of Bismuth, Tannalbin, small doses of Salol, Beta-Naphthol, and other intestinal disinfectants, may be employed after a distinct impression upon the disease has been produced by the Ipecac. The use of de-emetised Ipecac. has not been followed by the success expected. Some observers state that the disease differs very much in succeeding epidemics, and that when the Ipecac. treatment fails, then the method by Saline purges may be tried, Sulphate of Magnesia or Soda being given in 1 oz. doses with the view of flushing out the intestinal tract from stomach to anus, and this method has many advocates. Buchanan recently published his results of the treatment of acute dysentery by Salines in Bengal; 855 cases were treated with 9 deaths. 1 dr. of Sulphate of Soda was given in 1 oz. fennel water, 4, 6, or 8 times a day, till every trace of blood and mucus disappeared from the stools, which generally happened in 2 or 3 days.

Calomel (15 grs. in one dose) has been given for the same purpose, or in smaller doses (1 gr.), every hour or every two hours, as an intestinal disinfectant, combined with a little Opium. Castor Oil is exclusively relied upon by many physicians having large experience of the disease.

Astringents and full doses of Opium are not only useless, but do much harm in the acute stage of the disease. But there can be no objection to small doses of opium to allay vomiting at the beginning of the treatment, or to quiet tenesmus by the injection into the rectum of moderate doses of laudanum mixed with 1 or 2 ozs. starch mucilage at any time during the disease. Yeo advises the application of a solution of Cocaine to the margin of the anus before inserting the enema tube.

When malaria is present, full doses of Quinine must be given, and it is a good plan to administer the Ipecac. in the morning and at night, and one large dose (20 grs.) of Quinine in the middle of the day.

The introduction of the plan of treating dysentery by *Irrigation* alone or combined with Ipecacuanha has given satisfactory results. Different observers lay great stress upon the value of various antiseptics, but it would seem this is not of much moment, excellent results being attainable by the use of large quantities of sterilised warm water. Summer recommends Pepsin to be added to the water. Fouquet irrigates the colon by injecting a warm saturated solution of Boric Acid through a double tube, and

washing out the bowel with about 1 gallon of the liquid. Yeo prefers the use of a solution, containing 100 grs. to the pint, of Bicarbonate of Soda and Borax, with a little Camphor and Tincture of Eucalyptus. 1 in 1,000 of Quinine, 10 grs. Nitrate of Silver to 20 oz., 1 per cent. Lysol and 1 per cent. Creolin, 5 per cent. Alum, 2 per cent. Lactic Acid, 1 in 2,000 Corrosive Sublimite, 1 per cent. Acetate of Lead, and Thymol, Creosote, Iodine, Salicylates, and nearly every antiseptic drug have been used, and often with success. Ipecac. has been added to the irrigating water by some.

The hot bath is of great use in relieving pain and tenesmus, and when it fails an abdominal poultice and hypodermic of Morphia may be tried where a rectal injection of laudanum cannot be retained.

Children may be similarly treated, and a child two years old may get 4 grs. of the powdered root night and morning.

Shiga has applied serumtherapy in the treatment of dysentery with results which look most promising. He immunised the horse and sheep by injections of his bacillus dysentericus, which took two years in the cases of horses and one year for sheep. He injects daily 20 to 40 c.c. of their serum in cases of human dysentery, in divided doses, and his mortality was less than one-third of that in cases treated by other methods during the same periods.

Valagussa has reported favourably of serumtherapy in the dysentery of children. He injects the Celli-Valenti serum obtained by the subcutaneous injection of increasing doses of colitoxprotein.

In the *chronic* disease Ipecacuanha may be tried, but often fails. The first thing in such a case is to effect the removal of the patient from his old surroundings, to change his food, improve his blood, if there be any purpura present, by the use of pure fresh lemon juice, and keep him at rest in a warm, well-ventilated room.

Ten grs. of the powdered Ipecacuanha may be given every 8 hours, and if speedy improvement does not appear to supervene astringents must be tried. The best of these is 1 grain of Nitrate of Silver, combined with 3 grs. of Ipecacuanha, and $\frac{1}{2}$ gr Morphia, every 6 or 8 hours.

Ten grs. of Tannalbin may be given every 4 hours, or 3 grs. Acetate of Lead, combined with 1 gr. powdered Opium, Sulphate of Copper, Sulphate of Zinc, and Sulphate of Iron may be tried. A favourite remedy is the Liquor Ferri Pernitratis in 30 minim doses largely diluted every 6 hours, or 10 minims every hour.

Castor Oil has been used at different stages of the disease with some benefit, and Calomel was formerly given, but is seldom indicated. Any of the vegetable astringents may be tried. Enemata of Starch and Opium often give great relief to the tenesmus. Where the mischief appears to be confined to the

lower part of the great intestine, much benefit in very chronic cases may be obtained from rectal injections of Nitrate of Silver. Eight grs. dissolved in 20 ozs. of warm distilled water may be used to wash out the rectum, or a small enema, 3 grs. in 2 ozs. water, may be thrown up with the view of being retained.

All the agents mentioned above may be used for irrigating the bowel, the best results being obtained in the chronic affection by Nitrate of Silver. Indian authorities are divided upon the utility of the Bacl fruit in dysentery. Naphthaline, Corrosive Sublimate, Cannabis Indica, Turpentine, Eucalyptus, Crocote, Iodine, and nearly every antiseptic have been recommended internally, and used with varying success. The plan of irrigating with them is more rational, and gives greater hopes of cure. Drummond, of Ceylon, has demonstrated the value of a compound decoction of fresh Cinnamon.

Amœbic dysentery is generally found not to yield to Ipecac. The Calomel treatment has given better results, but it is necessary to combine it with large doses of Ipecac. Nearly every form of intestinal disinfectant has been recommended or tried. From the lethal action of Quinine upon the malarial parasite and many other protozoa specific effects were expected, but they cannot yet be said to be demonstrated. Splendid results have, however, been recorded by flushing out the colon with a 1 in 1,000 solution several times a day. Many other antiseptic liquids have been used successfully, and the best results are obtained by using these agents as enemata, which should be retained as long as possible when there is no danger of perforation. A strict typhoid fever diet, with rest in bed, is essential, and attention to all details liable to lessen the risks of perforation, liver abscess, hæmorrhage, or peritonitis.

Maberly has reported good results from the internal administration of $\frac{1}{2}$ oz. doses of the 1 in 8 tincture of *Monsonia Ovata*.

DYSIDROSIS or CHEIROPOMPHOLYX.

Any soothing ointment in the early stage will relieve itching; the best application will be 1 drachm of the Liquor Carbonis Detergens, with 1 oz. of Cold Cream or Vaseline. When the vesicles appear the patient should be at once put upon full doses of Arsenic and a liberal diet; 5 minims of Fowler's Solution need not be exceeded. Considering that the hands, and sometimes though rarely the feet, are the only part of the body attacked, the local treatment is easily carried out. Tilbury Fox recommended diuretics. Iron, combined with the arsenic at a later stage, appears to prevent new crops making their appearance. Everything that improves the tone of the nervous system and increases the body nutrition should be persisted in. Pringle states that alcohol, tea, and tobacco are injurious.

DYSMENORRHOEA

Is a symptom common to several conditions, local and constitutional, and its successful treatment can only be arrived at after a careful diagnosis of the cause of the pain. The difficulty is not lessened by the various attempts at classification, some authorities describing many distinct varieties of dysmenorrhœa, whose existence is denied by others.

Difference of opinion exists about the possibility of dysmenorrhœa being caused by mechanical obstruction, and without entering into the question one may say that there cannot be a doubt but large numbers of cases of painful menstruation have been permanently cured by dilatation of the external or internal os. It is just possible that the dilatation strikes deeper than merely causing a widening of the cervical canal; it may relieve a congested or inflamed condition of the lining membrane which may be the cause of the dysmenorrhœa. Leon divides all cases of dysmenorrhœa into those depending upon endometritis and those caused by uterine spasm.

Mechanical or Obstructive Dysmenorrhœa.—Where the symptoms of obstructed flow are present, and the patient suffers intense pain of a paroxysmal character followed by the expulsion of small gashes of blood or clots, which compels her to take to bed at each menstrual period, a careful examination may reveal obstruction at the os internum or os externum, or the narrowing may be caused by a sharp or acute flexion of the uterus, especially retroflexion. Should this latter condition be found present, it should be remedied by a suitable pessary. Malformations, tumours, and other sources of obstruction must be met by appropriate treatment.

Where there is distinct evidence of a marked narrowing of the cervical canal, or internal os, there is a fair ground for expecting relief by dilatation. The operation under an anæsthetic may be performed in various ways:—

(1) *Gradual dilatation* of the canal and internal os, by means of vulcanite or solid metal tapering bougies introduced at intervals of several days.

(2) *Sudden dilatation* by introducing one size of bougie after another at the same sitting, till the canal is restored to its fullest extent.

(3) *Rapid, forcible dilatation* by an instrument with diverging blades introduced through the internal os, and the blades separated.

(4) By the introduction of sponge, tupelo, or laminaria tents—a method always associated with danger.

(5) By incision followed by dilatation with the finger or sounds.

Marion Sims divided the external os with scissors, and the internal os with a long blunt-pointed knife.

The operation of dilatation is best performed by introducing a Sims speculum into the carefully sterilized vagina, seizing the

cervix with a stout vulsellum forceps, and introducing one dilator after another till the canal is fully opened up, when the uterine cavity is washed out with a weak disinfectant solution.

If any endometritis is found to exist the lining membrane should be curetted, and the cavity washed out and packed with iodoform gauze.

Apostoli's method of using the strong continuous current has a powerful influence over obstinate dysmenorrhœa, associated with a narrow pin-hole or and conical cervix.

Where the obstruction to the flow is caused by flexion the use of the intra-uterine stem pessary for 6 or 12 months sometimes effects a complete cure, but its use is attended with considerable danger.

Neuralgic dysmenorrhœa calls for rest in bed, when this is possible, during the attack, and a hot hip bath, or the immersion of the feet and legs in hot water and Mustard. Every possible cause must be sought out and remedied between the attacks, thus common causes are constipation, dyspepsia, and anæmia, and no permanent relief can be obtained till these are attended to. Anodynes must be given with great caution, chiefly on account of the danger of establishing the morphia habit. Alcohol for similar considerations must be seldom permitted.

Where the agonising pain is unusually severe, Chloroform or Ether may be administered sparingly. A hypodermic injection of $\frac{1}{2}$ gr. Morphia, with 1 minim of Solution of Atropia, may be given; $\frac{1}{4}$ to $\frac{1}{2}$ gr. Morphia may be given in the form of a pessary or suppository; or 1 to 2 grs. Watery Extract of Opium in suppository; or 30 minims of Laudanum as an enema, with a little starch water.

These measures should only be used under exceptional circumstances. Most cases obtain fair relief by the use of full doses of Antipyrine, Phenacetin, Antifebrin, or Exalgin; 10 grs. of the first mentioned drug may be given every hour for 3 doses till the pain is relieved. The writer has had much satisfaction from the following, which minimises the cardiac depressant action of the analgesic:—

R. *Phenazoni* gr. x.
 Caffeinæ Cit. gr. iiss.
 Sparteina Sulph. gr. i. *misce.*

Fiat pulvis. Sumat unam omni hora ad tertiam vicem dolore urgente.

The following amongst other drugs have been recommended:—

Chloral, in 15 to 20 gr. doses, relieves spasm and induces sleep. Than Cannabis Indica there is no safer anodyne, and small pills, containing $\frac{1}{4}$ gr. of the extract, may be given every hour

for 6 hours. The writer prefers this drug to opiates in dysmenorrhœa.

Beladonna, 1 to 5 minims of the succus, every hour for 6 hours.

Butyl Chloral, 2 grs. in pill every hour for 6 hours.

Nitrite of Amyl, by inhalation, or $\frac{1}{2}$ minim by the mouth every hour for 6 hours.

Nitroglycerin. A tablet may be divided into 4 fragments, of which one may be taken every 15 minutes till relief is obtained.

Cajuput Oil may be given in doses of one drop on sugar every hour or two, till 12 minims be taken.

Sumbul in doses of 10 minims of the tincture every 2 hours.

Castoreum has been highly praised by Champneys, who states that he has known cases treated by nearly, if not quite, all the usual drugs unsuccessfully, which got well suddenly as soon as this drug was given. It is best given in the form of tincture, twenty or thirty drops three or four times daily during the pain, with or without a few drops of Tincture of Nux Vomica.

Guaiaicum, alone or with Sulphur, is also much used by Champneys.

Camphor, 2 grs. in pill or 5 minims of the spirit every 2 hours, may be tried.

Apriol, in capsules containing 3 minims each, may be given every 2 hours for 6 or 8 times. It is very useful where severe pain precedes for a time the appearance of the flow.

Electricity, in the form of the continuous current, is valuable in this variety of the affection, especially if the flow is habitually scanty. 20 Leclanche cells may be used with one pole placed over the uterus or ovarian region and the other applied to the sacral region. Intra-uterine application is much more effectual, if there be no objection to its use.

Gelsemium, in 5 minim doses of the tincture every 2 hours.

Hamamelis, in the form of Hazeline, may be given in doses of 20 to 30 minims every hour for 10 or 12 hours.

Ergot, by stopping the irregular contraction, sometimes gives relief in moderate doses.

Bromide of Sodium, Potassium, or Ammonium, in doses of 30 grs. every 4 or 6 hours, relieves spasm and diminishes pain.

Valerianate of Zinc, Asafetida, Musk, Guaiacum and Saline Purgatives have been successfully used in many cases.

The passage of a graduated bougie, though no evidence may be present of any marked obstruction, has often led to most satisfactory results in spasmodic or neuralgic dysmenorrhœa.

Champneys points out that the os internum is the sensitive point for the uterus. By stretching this, years of dysmenorrhœal agony are concentrated into a few minutes, the irritability of the uterus is exhausted, it rests, and has a chance of starting afresh—a chance it may or may not accept. He looks upon dilatation as the last resort. It should be done under an anæsthetic.

be necessary to exceed 50 to 70. Twice a week during the intervals between the passing of the membranous casts will be enough for all ordinary cases.

Improvement of a moderate kind has followed the use of the continuous current when applied externally with one pole over the uterine region, and the other over the sacrum, and in those cases where the physician does not wish to suggest or carry out intra-uterine treatment, the external application of a strong continuous current, say from 30 Leclanche elements may be occasionally tried with some hope.

Champneys advises the scraping of the uterus *repeatedly* with an irrigating curette flushed with antiseptic solution, preceded by dilatation, and, upon the whole, this method is gaining in favour over electricity, and though it often fails, it seems to afford the best prospect of a permanent cure if repeatedly tried.

The violent pain during the attack must be met by anodynes and hypodermic injections of Morphia, a very mild inhalation of Chloroform, or sometimes the Nitrite of Amyl may be enough. Castoreum, Antipyrine, Cannabis Indica, Chloral, and the other remedies may be tried with advantage when the peculiarity of the patient forbids the ordinary narcotics being administered.

The danger of the Opium, Chloral or Alcohol habit becoming established must be ever before the physician, especially as the diseased condition is a very chronic one.

The general treatment during the attack will, in the main, correspond with that of neuralgic dysmenorrhœa. (Page 232.)

The bowels must be carefully attended to, and between the intervals everything that will improve the general condition should be insisted upon. Tonics are indicated, and of these there is no drug equal to Arsenic in moderately large doses, say 4 or 5 minims of Fowler's Solution thrice daily after food. Belladonna often does good when administered for 3 or 4 days previous to the attack, it should be given in doses of 10 minims of the B.P. tincture four times a day. Large doses of Iodides may be tried.

Removal of the appendages has been recommended, and is said to have been successful.

The treatment of so-called *Ovarian* dysmenorrhœa resolves itself into the management of the abnormal condition of the ovary. The most important remedy is the constant current applied by means of one pole over the ovarian region, and the other over the sacrum. The induced current should be tried every third or fifth week in a similar way.

Bromide of Sodium may be given in full doses, 15 grs., three times a day during the intervals, and as the expected menstrual period arrives this dose should be doubled to blunt the sensibility. The Iodide of Sodium has succeeded after the failure of the bromide, they may be combined advantageously.

A smart purge is of great value, and if there be a prolapsed ovary the rectum should be kept empty by copious enemata of

warm water. After the establishment of the flow the Bromide and Iodide treatment may be stopped for 14 days, during which small doses of Arsenic and Iron may be given with advantage, and moderate doses of Quinine may be substituted occasionally. During the attacks Indian Hemp, Opium, Chloral, or even Chloroform may in some cases be required.

Counter-irritation and hot stupes with warm water injections, hot baths, and local hot packs afford relief. Where there is evidence of ovarian congestion, leeching relieves the symptoms promptly, and one of the best of all means is the large glycerin wool plug inserted and left in contact with the os. Any remedy which obviates the constant use of narcotics should be persisted in, and to gr. doses of Antipyrine, or 5 grs. of Antifebrin are often invaluable, and may be safely used for long periods. Removal of the ovaries, if diseased, should be advised.

DYSPEPSIA.

The treatment of dyspepsia cannot be successfully undertaken till the cause of the condition be determined, and it cannot be too clearly insisted upon that dyspepsia is but a *symptom* of a large number of different affections. Thus the dyspepsia of gastric ulcer, cancer, dilatation, catarrh, &c., can only be removed by treatment aimed at the fundamental condition causing it. Ewald goes to the extreme in this, and practically does not recognise dyspepsia. Under *Neuroses of the Stomach* he describes atonic and irritative dyspepsias (but very imperfectly), and remarks that they occur chiefly in females. He states that it is just as absurd to write about dyspepsia "as if we were to write about dropsy as an independent disease, for we have long ago advanced from the symptomatic to the anatomical classification of disease." The physician will find that a large number of cases will present themselves where an anatomical classification will be impossible.

Acute dyspepsia generally means an attack of acute catarrh of the stomach, produced by the ingestion of some irritant, or by some error in diet, and, as a rule, rapidly subsides when the cause is removed. Total abstinence from food for 18 hours will often be found to entirely remove all symptoms. Painful attacks of acute dyspepsia generally are cut short when vomiting occurs, and this suggests to the physician the wisdom of giving an emetic and clearing out the contents of the stomach. If there be ineffectual attempts at vomiting already established by the patient there should be no delay in giving a large draught of warm water with a dessert-spoonful of salt in it, or 30 grs. of powdered Ipecacuanha, followed by copious draughts of warm water. The fauces may be tickled with a feather to hasten emesis, and the stomach washed out by large quantities of luke-warm water. Though there be no effort or inclination to vomit when the patient is first seen, if there be very severe pain, it will be good practice to give an emetic. Warm infusion of Chamomile, in

tea-cupful doses, is a splendid emetic in these cases. Should a considerable period have elapsed between the taking of a heavy meal and the patient being visited by the physician, and there be evidence of undigested food in the intestines, a smart purge will give speedy relief.

This may be also tried in those cases where vomiting has not already given relief. One oz. of Rochelle Salt, dissolved in a tumblerful of aerated water, or 2 oz. of the *Mistura Sennæ* Co. answer well. Epsom Salt, or any purgative, however, may be given with advantage. Ewald recommends Calomel.

There should in all cases be abstinence from solid food. Small quantities of milk and kaff water, or of arrowroot, should be taken at short intervals, and when nausea is distressing ice may be given and tea-spoonfuls of meat juice. Should vomiting persist, Morphia may be given, and by far the best form for the administration of the drug in such cases is a pilule or perule containing not more than $\frac{1}{2}$ grain, and made up into the smallest possible bulk and finished in globular form with a thin gelatin coating. They can hardly be rejected, even if the vomiting be continuous. An effervescing mixture containing Hydrocyanic Acid (2 minim doses) may be given. Sodium Bicarbonate is often efficient.

Bismuth, in the form of Carbonate or Oxide, in doses of 5 to 10 grs., is a favourite remedy, but the writer has seen little benefit from it in the vomiting of acute dyspepsia.

One large sinapism over the stomach may stop the nausea and vomiting at once. The quantity of liquids permitted should be very limited, and stimulants are often injurious. Tea-spoonful doses of good old whiskey, mixed with 1 oz. of soda water, will be the least objectionable.

The return to ordinary diet should be postponed for some days, during which the patient may live upon light farinaceous food, or milk puddings, with beef tea, or chicken soup, rennet, &c.

Where the recovery from the acute attack is slow or incomplete, or where the first attack is followed by a series of subsequent attacks, the treatment detailed under chronic dyspepsia will be indicated.

Chronic dyspepsia is one of the most obstinate affections which the physician has to deal with, and his chief object before commencing treatment should be to determine, if possible, the cause. (Often the term is used as a synonym for gastric catarrh.) There can be little good results obtained by feeding the patient upon drugs or chemicals whilst the cause of his ailment may be mental worry, gluttony, alcoholism, sedentary occupation, or other violation of some important law of health.

The diet should be most carefully attended to, and advice given, after minute cross-examination upon this point. It will often be found that the patient has been injuring his stomach by habitual and unvarying adherence to some restricted form of diet, whilst

he has, owing to some pre-conceived error in judgment, been abstaining from articles of food necessary to life. He may be, however, only paying the penalty due to constant gourmandizing or general excess in eating and drinking.

Speaking generally, one may say that it is a mistake for the physician to have a stereotyped dietary cut and dry for every form of stomach ailment, though this is a popular and "taking" method of treating stomach complaints.

Few cases of irritative dyspepsia come before the physician in which he will fail, after proper painstaking, to discover one or more serious errors constantly made in diet. The correction of these errors may alone afford the best or only method of treating the disorder satisfactorily.

It is not unusual to find dyspeptics living upon a diet so restricted as to seriously interfere with the general nutrition, because they attribute the discomfort following eating to one food after another, but but a few remain upon which they strive to live. After a time, irritative dyspepsia gives way to a hopeless atonic condition. Thus, vegetables are at first found to cause such distress that their use is gradually given up, and when the patient comes under observation he may be suffering from a condition bordering upon scurvy.

It will be found difficult or impossible to lay down a hard and fixed law about certain articles of food in dyspepsia, but there are certain dishes about which one can speak as being generally liable to serious objections. Thus pork, pastries, veal, boiled or stewed but especially *baked* meat, *re-cooked* meat, rabbit, salted or corned beef, sweetmeats, cheese, eggs, crabs, lobsters, nuts, pickles, crude vegetables, especially young potatoes, carrots, parsnips, turnips, cucumbers, and *very fresh bread*, should be forbidden, or only allowed in very small quantities.

Beefsteak properly cooked upon a gridiron, with all charred portions carefully rejected, is the most digestible animal food that the dyspeptic can eat. Roast beef and mutton, game, poultry, and boiled white fish can be taken with impunity in most cases. Vegetables belonging to the cruciferae generally are doubtful or hurtful, though the heart of cauliflowers may be used. Vegetable marrow, stewed lettuce, and celery are innocent. Farinaceous foods are, generally speaking, admissible, though sometimes they aggravate the mischief.

It is, however, always to be remembered that strong dislikes or marked prejudice against any food may cause it to disagree. The writer has verified, in his experience, the statement of Flint — "It is never advisable for the patient to adopt a restricted range, or any particular system of diet. On the contrary, it is important to persevere in attempting to digest all the varied forms of wholesome food not being restricted to a meat or a vegetable diet, but aiming to eat like persons in health without the need of particular care in the selection. I have never known a dyspeptic to recover

vigorous health who undertook to live after a strictly regulated diet, and I have never known of an instance of a healthy person living according to a strict dietetic system who did not become a dyspeptic. On the other hand, in a great number of cases in which persons have been sufferers for years on a regulated diet, health has been speedily regained by simply eating in accordance with appetite." It is for this reason that the writer considers that pepsin and other digestives are so valuable. They enable the dyspeptic to leave his restricted diet and launch at once into a generous and varied one, which is sometimes all that is required to effect a complete and speedy cure. The writer has seen serious and nearly fatal consequences follow rigid adherence to the raw beef steak and hot water treatment of dyspepsia.

The following are very common errors which lead to dyspepsia, and their correction is of great importance in the treatment of the affection. — Improper mastication of food, generally caused by haste in eating, or by want of teeth, too long or too short an interval between the meals (4 to 5 hours is a good average), drinking of large quantities of fluid at meal times, especially cold water or cold milk; the habit of taking stimulants, especially wines, and strong tea or coffee in excess between meals. Severe mental work or too active exercise immediately before or after a full meal is very injurious. Breakfast should not be taken immediately after getting out of bed.

See under Acidity, page 17, where the values of different foods are discussed.

Hygienic measures, which improve the tone and vigour of the general system are indicated—as suitable clothing (Branton recommends an abdominal flannel binder), a healthy residence upon an elevated, dry situation, open-air exercise; sea bathing; change of scene and, if convenient, of employment, with early hours; and freedom from occupations causing high pressure or mental worry. Agreeable society, especially at meal times, is of much use, and it is a good rule which prevents the dyspeptic from dining alone. The habit of reading while the patient sits at meals is very objectionable.

The medicinal treatment of dyspepsia is only to be undertaken after a thorough revision of the dietary as before mentioned. If constipation be present it should be treated by Cascara. (See under Constipation, page 166.) Purgatives should not be habitually used, but the occasional use of a mineral water—like Friedrichshall or Harrogate—is beneficial.

Anæmia, when present, must be treated with Iron; though, in irritative dyspepsia, this drug must be used with great caution. It can be given in pill form, coated with Keratine. In the atonic form it often gives unexpected benefits.

For the stomach symptoms in irritative dyspepsia, accompanied with chronic gastric catarrh, sedatives are indicated, and for routine treatment, especially when pain is present, the Carbonate

of Bismuth, in powder, in doses of 10 or 15 grs., is the most innocent gastric sedative. It may be given in a mixture suspended with mucilage. Hydrocyanic Acid may be combined with it. Morphia is of great service, but only in doses of very small amount; the local, not the constitutional, effects are required, and this object is gained by doses of $\frac{1}{4}$ grain.

Magnesia is a valuable gastric sedative, and may be advantageously combined with the Bismuth thus:—

R. *Bismuthi Carb.* ℥ij.
 Magnesæ Carb. ℥ij.
 Morphinæ Hydroch. gr i. misce.

Divide in pulv. æquales xvij Sumat unum quater in die hora una post cibos

Or,

R *Bismuthi Carb.* ℥v.
 Acidi Hydrocyanici dil. ℥j.
 Liquoris Morphinæ Hydr. ℥ii.
 Mucilaginis Acacia Recentis ℥iiss.
 Aquæ Chloroformi q. s. ad ℥iv. misce.

St. cochlearium unum min. quater in die ante cibos p. p. d.

Schacht's Liquor Bismuthi, in drachm doses, is a valuable gastric sedative where pain, nausea, or acidity is present. It is undesirable to prescribe large doses of Alkalies to be taken habitually for long periods, though a full dose of Bicarbonate of Soda often gives speedy relief to the pain of irritative dyspepsia where Bismuth and other remedies fail. Carbonate of Ammonia, or drachm doses of the Aromatic Spirit in a wine-glassful of kali water, will be a good substitute for the Soda Salt. Huchard recommends large doses of Bicarbonate of Soda, sometimes giving $\frac{1}{2}$ oz. in the day, and sometimes for long periods.

Antipyrine in doses of 5 grs. in tablet form, gives temporary relief, and capsules of Creosote are invaluable in some cases. In very chronic cases full doses of Nitrate of Silver ($\frac{1}{2}$ grain) given before meals have a good alterative action upon the irritable membrane. It should be given in pilular form, and only for brief periods. Two grain doses of the Oxide of Silver act in a similar way. Oxalate of Cerium may be tried as a sedative during the intervals of the silver treatment.

Where much mucus is vomited, astringents like Alum (5 grs.), Kino (10 grs.), Tannin (10 grs.), with Opium, may be given. Counter-irritation by means of Sinapisms, Leeches, Dry Cupping,

small Blisters, or a band of lint soaked in Diluted Nitro-Hydrochloric Acid (1 part of the dilute acid in 10 of water), worn round the abdomen under oiled silk or thin mackintosh, often materially relieves catarrhal stomach troubles.

If the dyspepsia be caused by a chronic congestion of the gastric membrane caused by valvular lesion, the circulation should be promptly relieved by smart saline purges of Mag. Sulph. in strong solution (8 drachms in 4 or 6 oz. water) to ensure emptying of the vessels. Afterwards dyspeptic symptoms disappear when the cardiac muscle is strengthened by a judicious course of Digitalis and Nux Vomica in small oft-repeated doses.

When the gastric trouble is caused by a catarrhal or inflammatory condition depending upon a congested liver, a smart mercurial (8 grs. Calomel) at night, followed by a saline, will give relief. Should the dyspepsia be a part of the phenomena associated with renal disease, treatment directed to the uræmic state may afford rapid relief. (See Bright's Disease, page 84.)

Sometimes the sipping of hot water frequently through the day may give ease, and dyspeptics often get relief by sipping hot water before breakfast. The writer has seen several cases of ulcer and perforation where he was satisfied that the cause was the constant sipping of very hot water commenced for a harmless functional dyspepsia. Small doses of the Mineral Acids, if given immediately before a meal, seem to check the secretion of the gastric juice, and in mild cases of irritative dyspepsia this treatment sometimes gives relief; it, however, often aggravates. After the more acute or painful symptoms have been got under, treatment suitable to the atonic condition may be cautiously commenced - Quinine, Vegetable Bitters, small doses of Iron or Arsenic. Ipecacuanha is very useful sometimes in small doses.

The medicinal treatment of atonic dyspepsia includes all remedies calculated to increase the functional activity of the stomach. Alkalies, if given in small doses before meals, have been demonstrated to increase the amount of gastric juice poured out by the enfeebled gastric glands, and when combined with suitable tonics are a valuable means of restoring function and improving digestion. The Bicarbonate of Soda is the best, but sometimes the Potash, Ammonia, Lime, or Magnesia Salt may be selected. In large doses, a few hours after meals, they act in a very different manner, and give relief by neutralising the excess of acid present in the stomach, as mentioned under the head of Acidity and Irritative Dyspepsia, and thus are of much value in relieving cardialgia and putting an end to acid fermentation. In atonic dyspepsia a good formula will be one containing 10 grs. Bicarbonate of Soda, with a few grains of Carbonate of Bismuth, and 15 minims of Tincture of Chiretta in 4 drachms of Infusion of Calumba or Quassia to be taken half an hour before each meal.

As a powder the following is an excellent formula :—

- R. *Sodu Carb. Exsicc.* ℥j.
 Pulv. Rhei ʒvj.
 Pulv. Calumbæ ʒj.
 Pulv. Zingiberis ʒiv.
 Pulv. Doveri gr. xxxv.
 Quinnæ Sulphatis gr. xxv. *misc.*

Fiat pulv. *Signa.*—"An egg-spoonful in a little water before each meal; or a tea-spoonful two hours after dinner if pain or acidity be distressing."

Notwithstanding the law formulated by Ringer that "acids check all acid secretions," there cannot be a doubt about the value of the mineral acids in the treatment of atonic dyspepsia.

Their value is believed to depend upon their supplying to the gastric juice the acid in which it is abnormally deficient, and they also are anti-ferments. In whatever way they act the digestive process appears to be hastened and rendered less painful in some cases, but to produce this effect the acid must be given some time after a meal.

The Dilute Hydrochloric or Nitro-hydrochloric Acid in doses of ʒo to ʒo minims, with Quassia, Calumba, Chiretta, or better still, with Nux Vomica, given after each meal, is about the best routine method of dealing with a chronic dyspepsia caused by deficiency in the gastric secretion or delay in the digestive process.

- R. *Acidi Nitro-hydrochlor. dil.* ʒv.
 Liquoris Strychninæ ʒiss.
 Tincturæ Auranti ʒj.
 Tincturæ Calumbæ ʒj.
 Infusi Gentianæ Co. ad ʒx. *misc.*

Fiat mistura. *Capiat cochlearium magnum post cibos ex cyatho vinario aque ter in die.*

Lactic Phosphoric, Nitric, and other acids are also very useful. Pepin in its various forms is of much value, but it never should be used to digest the food before the patient swallows it, as the result is an unpalatable mess owing to the bitterness of the by-products formed. Where artificial digestion is indicated the products obtained from the pancreas should always be selected, and Benger's Food is the most convenient form. The wine of Pepin may be given with dilute Hydrochloric Acid after meals. Lacto-peptine in 10 grain doses, with $\frac{1}{16}$ grain Morphine and 2 grains Quinine, may be given with advantage with or without Bismuth.

It is of little use giving it after purely farinaceous food. Pancreatin, Liquor Pancreaticus, or Trypsin are frequently prescribed, but these substances are rapidly injured by the gastric secretion. Papain has been used with much success by the writer in doses of 3 grs. after each meal, and he believes the following to be the best all-round routine formula for most cases of atonic and for some cases of irritative dyspepsia. He has hardly ever seen it fail, and it is decidedly better than Begbie's Pulvis Mirabilis, which consisted of 10 grs. Bismuth, 10 grs. Bicarbonate of Soda, 2 grs. Rhubarb, 1 gr. Nux Vomica, and 3 grs. Compound Powder of Cinnamon :—

R. Papain (Finkler) gr. iii.
 Mag. Carb. Pond. gr. xxv.
 Sodu Bicarb. gr. xxx.
 Morphia Hydr. gr. $\frac{1}{2}$. misce.

Fiat pulvis. Signa—"One after each meal in water."

Taka-Diastase, in 5 gr. doses, is very useful in the dyspepsia following the ingestion of starchy food.

The favourite recipe for atonic dyspepsia with the late Professor Gordon was one containing in each dose— $1\frac{1}{2}$ grs. Iodide of Potassium, 5 to 10 minims Ipecacuanha wine, and $\frac{1}{2}$ oz. Infusion of Calumba.

Flint highly recommended 10 grs. Salicin in 2 oz. water, swallowed immediately before each meal.

1 minim of Fowler's Solution diluted with 2 drachms water and given ten minutes before each meal, has been found to be followed with marked benefit in some cases.

1 to 4 drachm doses of Glycerin have been given with some benefit, a little Nux Vomica may be combined to destroy its intense sweetness, and some physicians combine with the glycerin 1 or $1\frac{1}{2}$ minims of pure Carbolic Acid. The Glycerin of Pepsin may be advantageously given with Nux.

Massage and the Continuous Current, if regularly used, are of much value as adjuncts to medicinal treatment in atonic dyspepsia.

Weltendorfer, during the treatment of an eczema of the trunk by means of an elastic rubber bandage, noticed the entire disappearance of obstinate dyspeptic symptoms, and was thus led to treat all cases of irritable or painful dyspepsia by compression of the abdomen with a broad rubber bandage applied for one hour after meals. The ordinary hydropathic belt applied over a warm pad suits some dyspeptics.

Washing out of the stomach has been used in some cases with marked success. It has also been highly recommended in the dyspepsia of infants and very young children. After the contents have been removed, a stream of tepid water, bearing in solution

some antiseptic as Boracic Acid, Creosote, Boroglyceride, Condy's Fluid, Salicylic Acid, or Sulphurous Acid, should be passed through the organ in order to thoroughly wash it out. The writer has had most satisfactory results with this remedy, even in violent gastralgia.

Yeo lays great stress upon the value of natural mineral waters in dyspepsia, and he states that no more brilliant results are obtained in medicine than those which follow courses of Carlsbad, Marienbad, Kissingen, Tarasp, or Brides-le-Bains, which are "tonic" in the best and truest sense, and not "lowering," the first-named in the irritative dyspepsia of the gouty and plethoric, and the others in the atonic forms. Ewald points out the great mistake of sending anemic and nervous patients to Carlsbad, and he states that Carlsbad and Marienbad are frequently the most dangerous enemies of these patients. Tarasp holds an intermediate position. On the other hand, he recommends Franzensbad, Ems, Neuenahr, Wiesbaden, and Kissingen.

For the various symptoms arising during the course of chronic dyspepsia, the previously mentioned treatment will, in the majority of cases, afford relief, but sometimes special measures must be taken. Thus for

Constipation, the writer has found that the minute perules of Morphia ($\frac{1}{2}$ grain) are, upon the whole, the most satisfactory treatment. See Bismuth (5 grains), Creosote (1 minim), Hydrocyanic Acid (3 minims), Codeine ($\frac{1}{2}$ gr.), Arsenic ($\frac{1}{100}$ gr.), Carbolic Acid (1 minim), Effervescent Mixtures, Champagne, Chloroform (1 minim), Tincture of Iodine (1 minim), and Ipecacuanha (minim doses, of the wine), have been recommended. This latter has signally failed in the writer's hands. Koumiss, Pepsin, Papan, Pancreatin, Lime Water, Nux Vomica (5 minims of tincture), or Cocaine ($\frac{1}{2}$ grain) may be tried.

Counter-irritation over the stomach is useful when sarcinae, with very yeasty, acid vomiting, are present. If Creosote fails, Sulphurous Acid (1 drachm), Sulphite of Soda (16 grs.), Salicylic Acid (10 grs.), Bichloride of Mercury ($\frac{1}{2}$ grain), Sulphocarbolates (20 grs.), Oil of Eucalyptus or of Mentha Piper (3 minims) may be prescribed.

Acidity, if it fails to yield to alkalis, will not likely yield to acids in small doses immediately before meals. The writer has found that the best routine treatment is the Creosote capsule, given 4 times a day. (See the various methods of treatment fully discussed under the heading Acidity, page 16.)

Hamilton has, by an exhaustive study of the contents of the stomach at different stages of digestion shown that in *acid dyspepsia* there is a distinct increase of acid present. Lactic and Hydrochloric Acids are normally present during digestion, but at different periods, and in acid dyspepsia it is Lactic Acid which is in excess. This is caused by a prolongation of the stage of lactic acid formation, and is favoured by the absence of the normal

amount of hydrochloric acid. Hence an obvious explanation of the benefit sometimes obtained by giving Hydrochloric Acid in these cases.

In other cases, however, large amounts of hydrochloric acid are formed, and this has been demonstrated to occur even during fasting. The only relief in these cases is to be obtained by large doses of alkalies.

The writer has satisfied himself that many cases of very severe acid dyspepsia are caused by great excess of butyric acid, and the cause of this is owing to the practice of stewing or baking fat meat for a long time at a high temperature in a close oven. The fat undergoes chemical change, and after being swallowed it readily ferments; and he has seen the contents of the stomach so highly charged with butyric acid that the epithelium of the throat has been removed or excoriated during vomiting, producing alarming symptoms. Large doses of alkalies, combined with Papain, afford the best means of meeting such a difficulty.

Roberts recommends that Antacids should be used in the lozenge form, he suggests that the B.P. Bismuth lozenge should be made without the Bismuth, and that 1 grain of Chloride of Sodium should be added in its stead. Vichy lozenges are excellent antacids for the dyspeptic. These antacids Roberts believes, when properly used, may be regarded as harmless, even when administered for very long periods. The Bismuth lozenges he advises should not be used till after the expiration of three-quarters or one hour following breakfast, and one hour or more after dinner. Lime water possesses very feeble antacid properties, 15 grains of Bicarbonate of Soda being equivalent to about half a pint of the B.P. *Liquor Calcis*.

Flatulence is often a most obstinate symptom of dyspepsia, and the patient should be informed that the regurgitant or expulsive effort which he naturally makes in order to expel the gas from the stomach always causes air to be swallowed. In this way the gaseous contents never diminish, though gallons of gas are belched off in a few minutes, and the distress of the patient increases. He should be convinced that it is a mistake to make any attempt to "raise the wind." Friction, kneading, or massage of the abdomen may be tried with a view of dislodging the imprisoned gas. Many of the previously mentioned remedies which stop fermentation and hasten the digestive process will soon arrest the secretion of gas. Creosote is again of great service. Sulphites, Sulphocarbolates, Pepsin in large doses, and Papain are also valuable. Carminatives like Ginger, Cloves, Ol. M. Pip., Cajuput, &c., give relief. Charcoal, freshly dried and given dry (wrapped up in wafer paper), or in capsules, affords comfort and assists digestion by causing rapid absorption of gas. Poplar Charcoal is preferred by many. It may be given with advantage before meals. Naphthaline has been given as a gastric and intestinal disinfectant, in 8 grain doses, with varying success. Salol and Salicylate of Bismuth are much better,

and when the flatulent distension is intestinal, these drugs should always be tried.

Alkalies, as the carbonates of Lime, Magnesia, and Potash, either alone or combined with Strychnine, often afford relief. *Anteſtā* should be given by mouth or enema if the flatus is intestinal. Foods likely to ferment or decompose should be avoided, as soups, eggs, starch, and fruits. A dry diet—beefsteaks, and biscuits of charcoal—is generally much more suitable than aqua nourishment, and the patient should be warned against taking much fluids after meals. Sometimes copious drinks of hot or warm water give relief, but their use ultimately aggravates matters. Alcoholic stimulants act in a similar way.

Ewald, as already mentioned, considers irritative and atonic dyspepsia as true gastric neuroses, and his treatment consists largely of anodynes like Morphia, Chloral, and Bromides, Massage, War Mitchell feeding, Lavage, Valerianates, Iron and Arsenic.

His favourite formula is the following, which he has proved very satisfactory in the irritative form, in hysterical hyperæsthesia, *catulgia*, and vomiting:—

R. *Morphiæ Hydrochlor.* gr. iij.
Cocainæ Hydrochlor. gr. vi.
Tinct. Belladonnæ ʒij.
Aquæ Amygdal. Amar. ad ʒj. *misce.*

Sig.—“Ten to fifteen drops every hour.”

EAR, Diseases of.

The treatment of *Eczema* of the auricle and meatus differs in no way from the treatment of *eczema* in other regions—the free use of an ointment in the early stages, containing 30 minims of *Liquor Plumbi F.* to 1 oz. *Vaseline*, with a few drops of a weak solution of the lead liquor (1 to 40), dropped into the meatus. After the acute stage is passed, *Liquor Carbonis Deterg.* may be added to the ointment with advantage. The meatus should be occasionally filled with warm Almond Oil, and all secretion gently removed by mopping out the passage by means of absorbent wool upon a probe. Nitrate of Silver, 10 grs. in 1 oz. of Spt. *Æth. Nit.*, freely applied to the affected parts, is also a useful treatment.

Hæmatoma of the auricle is best treated by a free incision, and dressing with a weak Spirit Lotion (1 to 5) to which Perchloride of Mercury ($\frac{1}{2}$ gr. to 1 oz.) is added.

Bony Growths, or aural exostoses, when blocking up the meatus, are best removed by gouging, by grinding down with a dentist's drill, by sawing with the *ceraseur*, by inducing caries through the use of the trephine, or through the use of a strong continuous current; the various methods suggested for dilating the meatus with tents or plugs without removing the growths are condemned by the best authorities.

Inflammation of the external meatus is most commonly caused by the presence of small furuncles, boils, or abscesses; these occur with disheartening regularity and frequency, and render the treatment of this condition most troublesome.

In the acute and intensely painful stage prior to the pointing of the abscess, leeches to the auricle, followed by hot stupea, give relief. Cocaine--the pure alkalioid dissolved in warm oil (4 per cent.) affords some ease when dropped into the meatus; but to relieve acute pain in the ear, whether from the meatus or the tympanic membrane, the best application is a solution of 10 per cent. each Cocaine and Carbolic Acid in water. A very few drops poured into the ear out of an egg-spoon (previously warmed) seldom fail to give relief.

Von Stein extols a combination of Cocaine with Resorcin, which relieves pain, and increases the absorbent power of the blood vessels, diminishing secretion in a marked degree. He uses about 5 grs. of Resorcin and 25 grs. Cocaine in 1 oz. water, and drops a little into the ear where it is allowed to remain for a short time before being soaked out on wool. Abscesses should be opened with a fine-pointed abscess knife, and speedy relief follows.

MacCuen Smith cleanses the canal with alcohol, and applies tampons of Camphor-Phenol (carbolic acid 45, camphor 55 parts).

Since the writer learned that the pathology of these furuncles was probably parasitic, he was led to employ a solution of Corrosive Sublimat in them after-treatment with a view to prevent their recurrence, and the result was most satisfactory.

In one case which had lasted for years, notwithstanding the measures employed by more than one eminent specialist, the life of the patient was made very miserable for short periods every few weeks. The disease did not return after the use of the following solution had been commenced, though some years have elapsed. It was dropped into the ear twice a day, and afterwards once a day, and the orifice of the meatus plugged with cotton wool also moistened by the solution:—

R. *Hydrargyri Perchloridi* gr. ii.
 Spirit. Vini Rectif. ʒvi.
 Aqua Destillata ad ʒiii. misce.

Fiat solutio. Signa.—"To be applied to the inside of the ear on cotton wool."

Where the inflammation of the meatus is general and not depending upon furuncles, leeches, fomentations, and weak astringent injections, followed by dry Boracic Acid, speedily cure the disease.

Fungi—*Aspergillus flav* and *nig.*—are sometimes found infesting the meatus. They may be easily destroyed by the above liquid,

diluted with an equal quantity of water. Dry Boracic Acid insufflated, or a warm strong alcoholic solution, soon causes their destruction.

Wax and Foreign bodies in the meatus are best removed by syringing with warm water. The ordinary India-rubber enema apparatus answers very well, and it is hardly necessary to say that the nozzle should not be introduced *within the meatus*, but should be held within a few lines of its orifice.

The auricle when pulled upwards and backwards permits the free flow of water in and out of the meatus, and by persevering for some time, the stream, getting behind the cerumen or foreign body, forces it out. If this fails, variously-shaped instruments devised for the purpose may be used, about the best is a loop of wire, gently coaxed past the obstruction and drawn forwards. The loop end of a fine polished hair-pin answers all purposes. Forceps, or a very small scoop, may occasionally be required.

Should there be much difficulty in removing the wax, it will be well to adjourn operations for a time, as prolonged syringing sometimes causes faintness, tinnitus and deafness owing to congestion or extravasation in the labyrinth. The introduction of a little solution of Bicarbonate of Soda ($1\frac{1}{2}$ grains to each drachm) for a few days greatly assists in the removal of the wax. Papan also assists the disintegration of wax and other concretions.

MIDDLE EAR, DISEASES OF.

Acute Catarrh of the Middle Ear, if severe, will be best relieved by the application of 2 or 3 or 4 leeches to the auricle.

Hot fomentations will encourage the bleeding from the bites, and give further relief. Should the pain be severe and the tympanum found bulging, an incision with a fine, sharp double-edged knife or needle gives speedy relief.

When the symptoms are not very acute, the case often yields to a few insufflations of the tympanum by Politzer's bag. By inserting the nozzle of an ordinary enema apparatus well up into the nostril of the affected side, and forcibly injecting air at the instant when the patient is in the act of swallowing a little water, the air is driven through the Eustachian tube, and obstructions caused by accumulations of mucus may be easily overcome.

The naso-pharynx may be douched with weak saline solutions—Boracic Acid, Chloride of Sodium, Borax, or Bicarbonate of Soda (100 grs. to half a pint of tepid water). Dry Boracic Acid in fine powder may be blown up the nostril by means of an insufflator.

If the catarrh resists the above treatment, and shows signs of passing into the chronic form, the Eustachian catheter may be passed, and a weak astringent solution, if there be evidence of much mucus secretion, should be injected. The strength of the solution varies, but generally speaking about the strength of an eye lotion—1 gr. Zinc Sulphate to 1 ounce warm water. If the tympanic cavity contain thickened mucus—the remnants of an acute attack—some experts make a linear incision in the tympanic

membrane, and, through the Eustachian tube by means of the catheter, wash out the cavity by a stream of weak alkaline solution injected into the external meatus. A less heroic measure to promote the absorption of effused products in the middle ear is blistering over the mastoid, from which great benefit is sometimes derived.

Chronic Catarrh of the Middle Ear is best treated by remedial agents directed to the cause of the obstruction often existing in the Eustachian tube, constant inflation of the tympanum by Politzer's method, or the Eustachian catheter, with attention to diseased conditions of the naso-pharynx by local applications, or by the Chloride of Ammonium Inhaler. In very bad cases the incision of the membrane, and the injection of alkaline solutions, as just mentioned, may be tried, or Leil's operation for division of the tensor tympani muscle may be suggested. Bronner reports that intra-tympanic injections arrest the progress and in some cases improve the hearing. He draws attention to the fact that in most cases the left ear in men becomes affected first; the treatment may prevent extension. After trying numerous drugs, he relies upon a 3 per cent. solution of Bicarbonate of Soda, with equal quantities of Glycerin and water or Paroleine. The injection must be sterilised, and used warm, 20 or 30 minims may be injected by a Pravaz syringe through the Eustachian catheter, air being blown in afterwards. Another form of treatment widely used is the injection through the Eustachian catheter of a few drops of a solution of Menthol, 20 grs., and Thymol, 5 grs., in 1 oz. Liquid Paraffin.

Acute Purulent Catarrh should be treated just as if a case of acute simple catarrh of the middle ear, from which at first it cannot be distinguished. If perforation of the membrane has already occurred, there may be afterwards difficulty in getting the opening to close. It is better for this reason to incise the membrane early if the case comes under notice before perforation has occurred. Constant syringing with weak antiseptic solutions (10 grs. Boracic Acid to 1 oz., or 3 grs. Zinc Sulphate to 1 oz. water) must be carefully done at least twice daily.

Muller strongly advises early paracentesis for the abortion of acute inflammation of the middle ear. He succeeded in 23 out of 24 cases, and no after-treatment was required.

M. Shield has directed attention to the difficulty in having agents in the dry state applied to the interior of the ear, and he has wisely recommended the use of small pellets or round suppositories about the size of swan-shot, which quickly melt in the meatus and keep it aseptic for hours. In this way Iodoform, Tannin, Boracic Acid, and other agents may be easily used by the nurse or patient's attendant.

Inflation of the tympanum by Politzer's method should be daily performed before syringing.

Mastoid swelling and tenderness may occasionally be relieved

by one deep incision, but if pus is found, more vigorous measures must be at once adopted. (See under Mastoiditis, on this page.) The condition of the naso-pharynx must be carefully made right by local astringents and antiseptics. Gargles—Tannin (1 in 30), Chlorate of Potash (1 in 40), Carbolic Acid (1 in 80)—may be employed. It is a good plan to brush out the throat with Glycerin and Carbolic Acid (1 in 10), Tincture of Iron and Glycerin (1 in 2), or Nitrate of Silver (1 in 20).

Chronic Purulent Catarrh requires treatment generally for the perforated state of the membrane. Constant syringing, with very weak Carbolic solution (1 in 20), and insufflations of dry powdered Boracic Acid are the safest means of restoring a healthy condition of the affected parts. An instillation of warm alcoholic solution of Boracic Acid (1 to 20), or of strong Spirit of Wine may be tried, or where the discharge is offensive 5 grs. each of Sulphate of Zinc and Carbolic Acid to 1 oz. water.

Mackenzie Johnston has used a solution of Papain for cleansing the middle ear in case of suppuration, with the view of causing disintegration of the masses of dry pus or *debris*. He drops in 15 minims of a five per cent. solution into the ear so that it may reach the bottom of the meatus. One hour afterwards the ear is to be syringed out with warm Boracic Acid lotion. Papain should be a good means of treating cholesteatoma of the middle ear by means of the syringe and tubes used by Dundas Grant.

The Eustachian tube should be daily kept clear by inflation. Exuberant granulations round the perforations may be kept in check by the application of caustics as the solid or mitigated stick, or Chromic Acid. Ultimately the opening, if it does not close of itself, may be temporarily stopped up by an artificial tympanum of India-rubber like Toynbee's, or of the membrane which lines the interior of the egg of the common hen, or the opening may be closed by a moistened plug of absorbent cotton wool pushed through the meatus by means of special forceps till it rests against the perforated membrane. This plug or pad should be renewed every morning.

Mastoiditis should be promptly met by leeching, and as soon as pus is evident, a large, deep incision, down to or through the periosteum. If matter be not reached and brain symptoms are present, trephining should be resorted to without delay. Where dead bone exists, its early removal is necessary.

Polypi, which commonly appear during the course of chronic purulent catarrh, should be removed by the snare, forceps, or ring-knife.

INTERNAL EAR, DISEASES OF.

The treatment of the various groups of symptoms found associated with abnormal conditions of the nervous structures in the ear is very unsatisfactory.

Syphilitic affections, if of very long standing, are almost hopeless. Mercury by inunction in the early stages will give good results.

At a later period, large doses of Iodide of Potassium (20 to 30 grs.), with frequent mastoid counter-irritation, may be tried.

Tinnitus Aurium may be treated, with some slight benefit, by large doses of Bromide of Sodium, 30 grs. three times a day. The various suggestions for electricity, puncture of the tympanum, &c., are generally useless. Counter-irritation by blisters over the mastoid is occasionally of service, specially in cases which are not of long standing. The instillation of Cocaine has sometimes given considerable relief, and this is supposed to result from its influence on arterial pressure.

Menière's disease has been treated with occasional success by large doses of Quinine (5-10 grains), Bromides (30 grains), Salicin or Salicylates (30 grains), Digitalis, 10 minims of the tincture, every 4 or 8 hours, has been tried along with counter-irritation over the mastoid and the Continuous Current. More recently, excellent reports have been made of the value of hypodermic injections of Pilocarpine in small doses. (See also under the separate heading of *Tinnitus*.)

ECLAMPSIA—See *Puerperal Convulsions*.

ECTHYMA.

The original affection which is the cause of this must be treated. Thus prurigo, scabies, pediculosis, or any condition or affection of the skin accompanied by much itching may be the origin of ecthyma and this condition will rapidly disappear upon the removal of these causes. The affection is generally only seen in the filthy, those badly fed and unhealthy, and the indications in such cases are scrupulous cleanliness, good plain food in abundance and improved hygienic surroundings, with Cod Liver Oil, tonics, and proper clothing. The local treatment must be directed to the primary affection, crusts and scabs should be removed by poulticing or warm water, and a mild astringent ointment then applied to the base of the pustule. Zinc ointment with $\frac{1}{2}$ drachm of *Liquor Plumbi* and 10 grs. White Precipitate to each ounce answers well in most cases, or Dilute Ungt. Hydrarg. Nit. may be used with advantage. Lotions covered by oiled silk are to be avoided. Many authorities now regard ecthyma as a variety of impetigo contagiosa, and always caused by the same micro-organism. In any case the above treatment will be the best, and great attention should be paid to the relief of itching, as the consequent scratching inoculates the disease on fresh parts. Morris washes the surface with Boric Acid solution, and applies a weak Mercurial or other antiparasitic ointment.

ECTROPION—See *Entropion*.

ECZEMA.

The treatment of this common ailment is one of the most difficult problems that come before the physician. Unfortunately

there are some cardinal principles about which authorities differ, but too much is made out of these differences. The vexed question of the local *versus* the constitutional origin of eczema is a stumbling-block. It appears almost certain that both views are correct, and the error to be guarded against is the common one of taking either side of the question to the exclusion of the other. Thus at the start is a matter of vital importance as regards treatment. The physician who always regards eczema as a purely constitutional disorder, to be purged out or drugged out of the system will continue to treat an eczema with internal remedies long after the constitutional condition which caused it has been remedied. Upon the other hand, he who looks at the ailment exclusively from the local standpoint may find himself treating a case of the disease solely with topical remedies long after the original local cause which called the eczema into existence has disappeared, the condition being, in the meantime, kept up by some constitutional error. This constitutional error may be a factor possessing enough power to keep up the eczema when once produced by a local irritant, though it possibly, of itself, might never have been able to establish the disease. Hence the treatment of eczema must be both constitutional and local, and clinical experience amply proves that *the local treatment is much more successful in the great majority of cases*. Many authorities believe now in the parasitic or microbic origin of the disease, and consequently their treatment is entirely local, and it is most interesting to observe how this theory has changed the local treatment in late years: drugs which were forbidden as dangerously irritating are now frequently recommended, as Corrosive Sublimate, Sulphur, Chrysarbin, &c. Doubtless the reaction will soon set in in favour of the older and well-tried remedies. Unna has separated various cocci which he believes to be the cause of the disease. He states that numerous micro-organisms are present, and among these are several which, when re-inoculated, reproduce eczema, and he insists that eczema is thus a contagious disease and under certain conditions can become epidemic. His conclusions are stoutly denied by many dermatologists, who affirm that the early vesicles are absolutely sterile. It is probable though the disease is not parasitic in the first instance, that secondary infection may play a very important part in its development.

Diet must be carefully attended to, especially in acute cases, and, upon the whole a purely milk diet in the absence of special contra-indications, is the best where any considerable portion of integument is involved.

In chronic cases a good, generous mixed diet may be permitted, but sugar and coffee in any quantity should be forbidden, and all salted meats, pork, shell-fish, cayenne, spices, pickles, raw fruits, pastry, and cheese should be partaken of with caution. Any food or article of diet which the patient has found to aggravate the itching in the eczematous spot must not be again indulged in.

Some patients feel that the smallest sip of wine, in a very short time after being swallowed, produces tingling and itching in the seat of the eczema, and this is especially true if the head, face, or neck is affected. Upon the whole, stimulants must be allowed in very sparing quantity, and, where indicated, whiskey is the best. Acid wines are especially hurtful, and beer, as a rule, should be forbidden. In the presence of dyspepsia, or other gastric trouble, the dietary suitable to the patient's needs must be selected.

Everything that will improve the hygienic condition of the patient, as to proper rest, exercise, sleep, clothing, sunshine, cookery, &c., must be seen to when found to be faulty.

Change of air, scene, and occupation affords marked benefit in some cases but a bracing sea air or sea voyage is not to be recommended without serious misgiving, and sea bathing is generally harmful.

Internal treatment may be summed up by saying that the object of medicinal interference should be to correct any abnormal conditions present in the organs or secretions. Thus dyspepsia, or acidity, should be counteracted by appropriate remedies, and constipation by laxatives or purgatives. The use of these latter in chronic eczema is universally acknowledged. Salines are especially valuable. Friedrichshall, Carlsbad, Püllna, Hunyadi Janos Waters, or Rochelle or Epsom Salt may be used. There is no better saline than the "White Mixture" given early in the morning whilst fasting, so as to produce one or two copious motions of watery consistence.

R. *Magnesi Sulphatis* ʒiii.
 Vini Colchici ʒii.
 Magnesi Carbonatis ʒiij.
 Aquæ Mentha Pip. ad ʒxii. misce.

Fiat mistura, cujus capiat cyathum vinosum plenum omni primo mane.

Another favourite saline combination in these cases is:—*Magnesi Sulphatis*, ʒss. ; *Ferri Sulphatis*, ʒss. ; *Acid. Sulphurici Dil.*, ʒss. ; *Aquæ Destillatæ*, ad ʒxvi. ; misce. Signa—"A large wine-glassful to be taken in half a tumblerful of water every second morning, and to be repeated in three hours if the bowels be not well moved."

The saline should be occasionally preceded by a good dose of Blue Pill, given at bed-time. It is manifest that this purgative treatment cannot be pursued for long periods without serious drawbacks. In the intervals the bowels will likely become very obstinate, and *Cascara* or *Aloes*, in properly-regulated doses, as mentioned under "Constipation" (page 167), should be employed.

Where the tongue remains furred and appetite bad, especially

where there is a dry skin and scanty urine, an effervescing mixture containing 1 oz. Bicarbonate of Potash and 1 drachm Acetate of Potash, dissolved in 10 oz. water, may be given in doses of 1 oz. with $\frac{1}{2}$ oz. fresh lemon juice three times a day, to be swallowed during effervescence.

Where eczema is associated with anæmia there is no iron preparation better than Bland's Pill, but iron must not be given in acute cases.

In chronic cases associated with enlarged veins and a weak heart or diseased mitral valve, the eczema of the lower extremities is much improved by a combination of Iron and Digitalis.

Internal remedies may be called for to allay itching and sleeplessness. Opium, Morphia, or Chloral should be used for this purpose with the greatest caution. Sulphonal, in 20 grain doses, may be tried, but large doses of the Bromide of Sodium (30 grs.) allay restlessness, without producing any untoward results.

Pye-Smith strongly recommends Chloral in the eczema of children in order to ensure sleep and prevent scratching.

Gelsemium may be given alone or in combination, it sometimes allays itching in a marked degree (10 minim doses of the tincture). Belladonna or Hyoscyamus in full doses may give sleep where Opium cannot be given on account of its after-effects upon the nerves of the skin. Quinine has the power of preventing itching in young subjects when given in full doses 1 hour before bed-time. Antipyrine is better, and acts when given in small doses.

Tartarised Antimony certainly appears sometimes to have a modifying effect upon the course of eczema, especially in the more acute or sub-acute cases. Small doses only should be given. $\frac{1}{2}$ gr. in solution three or four times a day may be given for to days. M. Morris regards antimony as the best drug in all acute cases where the arterial tension is high.

Phosphorus, Strychnine, Hypophosphites, Phosphates, Malt preparations, Cod Liver Oil, Iodides, Chlorate of Potassium, Iris Versicolor, Lithium, Viola Tricolor, Rhus Toxicodendron, Tar, Ergot, Sulphide of Calcium, Turpentine, Copaiba, Guaiacum, and scores of other drugs have been vaunted from time to time as specifics for eczema when administered by the mouth.

Arsenic is, however, a valuable drug in *chronic* eczema, and it is indeed the only drug which in our present knowledge can be said to constantly modify the diseased action in this troublesome ailment.

It may be stated, as a rule, that Arsenic is of value in proportion to the *chronicity* and dry or scaly state of the eczema, and it is almost equally true that it is injurious in the acute stage, and should never be given then. One might safely tell the student that the nearer a case of dry chronic eczema, with its scaly surface and thickened base, comes to resemble psoriasis the more clearly does the internal use of arsenic become indicated.

It should be given in full doses, beginning with 3 minim doses

of Fowler's Solution after each meal, and in about a fortnight 10 minim doses may be reached.

Cacodylate of Soda is now vaunted as the great French remedy (see page 44). Hutchinson regards eczema as a local disease, and he believes that Arsenic rarely does good, and that it often irritates.

Pilocarpine has been given hypodermically in cases where the skin has remained dry and harsh, and good results have been reported.

Electricity, in the form of the continuous current, has been used with advantage in inveterate cases.

Blisters applied over the vaso-motor centres of the affected part are recommended by Crocker in those severe cases where fresh exacerbations occur at short intervals.

The local treatment of eczema might easily be made to fill a volume larger than the present. Only the more important leading principles and chief details can be enumerated. There is no specific for eczema—no royal road to its successful treatment—though there are few diseased conditions so susceptible to improvement or permanent cure. The secret of success in treating eczema lies for the most part in the ability of the physician to use the proper remedy at the various stages of the disease. The class of agents so valuable in the acute are worthless in the very chronic stages, whilst remedies of unfailing power when used in the chronic cases are fraught with serious danger when applied at the earlier stages of acute cases. The physician who wishes to treat the protean forms of eczema with success must learn to be patient, ever remembering that in the majority of cases the progress towards recovery is a slow one, and having fixed firmly before him the principle upon which his treatment is based, he should be content to wait till his local remedy has had time to act, before its failure is accepted. The constant chipping and changing of applications from day to day is one of the great causes of failure in the management of chronic or acute eczema.

The writer, before he had realized the natural progress of the affection through the hyperæmic to the papular, vesicular, pustular, weeping, scabbing, and scaly stages, had much disappointment in the results of treatment. He can recall cases now which were progressing towards recovery when an unfortunate impatience tempted a change in the local remedy, and caused the disease to break out afresh and run through all its stages over again. Had the treatment only been continued for a few days or weeks longer in these cases, uninterrupted recovery would have been the result.

Acute Eczema calls for soothing and bland applications. If seen at the very early stage the treatment should consist in the free smearing over of the part with an inert oil or grease, to protect the irritated surface from the action of the atmosphere or from

changes in temperature. But it is useless to cover over the seat of disease with ointments till scabs or altered or dried secretions have been thoroughly removed. These must be removed by one good cleansing with saturated Boric Acid solution, soap and water, by poulticing, or by bathing. This application of soap and water should not be repeated, and the rule should be laid down that the parts affected with acute eczema should not be washed, soaped, or poulticed till convalescence is fully established. At a later stage and during the progress of treatment, secretions may be easily removed by applying olive oil freely upon absorbent wool and gently wiping the part clean. If soap must be used, an over-fatted basis soap should be selected. Everything that can cause irritation, such as the friction of the dress rubbing against the part, profuse sweating, alterations of temperature, exposure to the air, scratching, &c., must be guarded against.

In the early acute stage the indication is, as just mentioned, to soothe, cover over the painful part, and to protect it from all external sources of irritation. For this purpose Lotions, Dusting Powders, Pastes, Oils or Ointments may be applied, and it is difficult to lay down any fixed rule for the selection of these remedies. The writer seldom uses lotions at this stage, unless astringents are required. Lotions must be applied on lint, and should not be covered with oiled silk, as they soon become poultices if this be done. The lint should never be allowed to dry, but constant moistening with the lotion must be kept up. This is impossible at night, ointments are consequently much more convenient, and the best one for routine treatment is the Unguentum Zinci Benz. It may be made of firmer consistence by the addition of more of the Oxide or of the impure Carbonate. The following is a good formula:—

R. Unguent. Zinci Benz. ℥ii.
 Calaminæ Præparatæ ℥ii. misce.

Fiat Unguentum.

Or,

R. Cremoris Frigidæ ℥ii.
 Zinci Oxidi ℥ii.
 Calaminæ Præparatæ ℥j. misce.

Fiat Unguentum.

Or M. Morris' formula may be used.—R. Aquæ Rosæ, 3x.;
Olei Amygdal. 3x.; Cerae Albæ, ℥j.; Cetacei, ℥j

This is a valuable basis for all other local remedies in eczema.
Powdered Arrowroot, 1 dr.; Oxide or Carbonate of Bismuth,
1 dr.; Cold Cream, 1 oz., make a bland, soothing covering.

Formulae might be given to any extent--the above meet most requirements. The ointment should be freely smeared over the surface, which should be then covered with lint or old linen, upon which a layer of the ointment has been evenly spread. Pure Olive, Almond, or Linseed Oils, or any of those mixed with an equal quantity of Lime Water, may be used. If secretion be profuse, after the mild ointment has been used for a few days an astringent should be added to it. Lead in some form is the best. 1 drachm of the strong liquor of the Subacetate may be added to each 1 oz. of Zinc Ointment. Hebra's Diachylon Ointment is a good one.

It is in those cases of acute weeping eczema that lotions may be used for a time with advantage. The dilute Subacetate of Lead Solution is a favourite; a few minims of Laudanum may be added to each ounce.

In acute eczema, with very profuse secretion, powdered Starch, Arrowroot, Carbonate of Lead, Carbonate of Zinc, Carbonate of Magnesia, Powdered Fuller's Earth, Oxide of Zinc, French Chalk, Bismuth Oxide, Nitrate or Carbonate, Lycopodium, Powdered Rice, and Talc may be mixed in various proportions, according to the amount of astringent action required, the lead being the most active in this respect.

Where itching is smart, Camphor in fine powder should be added to the above in the proportion of about 10 grains to each ounce of powder.

Pastes are becoming extensively used in the treatment of eczema. They possess the great advantage of absorbing the aqueous secretions of the skin, which are pent up under the ointments, and they leave a firm powdery residue on the skin not easily removed by friction, thus fixing the active ingredient.

Lassar's Paste consists of 2 oz. Vaseline, 1 oz. Starch, 1 oz. Oxide of Zinc, and 40 grs. Salicylic Acid. With this paste he envelopes the entire body of an infant suffering from acute eczema, after having previously washed it, and touched any bleeding spots with a solution of Caustic. The face, head, and joints are smeared over with a 2 per cent. ointment of Salicylic Acid in Vaseline, and muslin bandages are firmly applied.

Unna makes a paste by adding a small quantity of Silica to Zinc Ointment. Bulkley adds to the Zinc Ointment a small quantity of Ichthyol and Salicylic Acid, and thus makes a very efficacious combination.

Lanoline, Lard, or Vaseline may be used as the basis of a paste made with any of the previously mentioned powders.

Glycerin in undiluted form should never be used in acute eczema. Unna's Glycerin Jelly consists of Glycerin, 25 parts; Water, 45 parts; Gelatin, 15 parts, and Oxide of Zinc, 15 parts; to which any ingredient may be added. Unna allays the burning itch of acute dry eczema by painting on this paste warm with a camel's hair pencil.

Salve Muslins consist of muslin whose meshes are saturated with Benzoated Lard and Wax, to which any of the usual remedies may be added. Plaster Muslins, made upon the same principle, are used in chronic cases.

Morris (probably on the parasitic theory) recommends the use of an ointment consisting of 10 grs. Precipitated Sulphur to 1 oz. Benzoated Zinc Ointment. Resorcin and Ichthyol he also recommends.

Picric Acid in saturated watery solution is recommended by a large number of dermatologists in all weeping eczemas. The solution may be applied on lint.

Should the acute eczema not resolve within a short time under the above treatment, more stimulating measures will be called for, and it may clinically be regarded as a case of sub-acute or chronic eczema, and treated accordingly.

Chronic Eczema.—If the affection has failed to respond to the soothing treatment, or if it has existed for a considerable period before coming under observation, applications of a more stimulating nature are demanded. The list of local remedies for chronic eczema seems almost without end. The old drugs, which have stood the test for ages, are after all better, more certain, and more innocent than their modern rivals. Thus Tar, Mercurials, and Lead will cope, if skilfully handled, with most chronic forms of the disease. Upon the whole, ointments will be found more convenient and efficacious than lotions, though these latter are indicated under special circumstances. If there be very much exudation or moisture, the greasy nature of the ointment keeps the secretion in contact with the irritated surface. In some cases this is a serious drawback, and the discharge is, of itself, an irritant, and prolongs the mischief. In these cases a lotion containing an astringent must be used to check secretion. After an appreciable effect has been obtained in this direction, a stimulant like Tar can be combined with the astringent lotion. The amount of stimulating ingredient must be small at first, and gradually increased, the physician cautiously feeling his way before employing strong remedies.

A Tar preparation which may soothe and quickly heal an itchy, dry eczema, associated with much infiltration, may act like fuel to the fire when applied to a moist, weeping, red eczema. It is a good rule, with chronic, weeping eczemas of this kind, to begin with Lead Lotions containing a sedative to allay itching and heat; afterwards Tar can be safely used.

The strong Liquor Plumbi in water (1 to 40), to which a $\frac{1}{2}$ part of Laudanum or Camphorated Spirit is added, soon allays itching and diminishes secretion, but the number of cases in which an astringent ointment cannot be used instead is small. Liquor Carbonis Deterg. may be added to the above lotion with advantage (1 to 80.)

One of the best ointments ever used in chronic eczema is the

following. It is astonishing to find the number of cases in which it can be used advantageously. The proportions of the different ingredients may be altered to suit the symptoms or peculiarities of each case.

R. *Liquor. Carbonis Deterg.* ℥i.
 Hydrarg. Ammon. Chlor. gr. x.
 Lanolin ℥i. *misce bene.*

Fiat Unguentum.

If much secretion be present, one drachm *Liquor Plumbi* may be added. Should there be dryness instead, with scaldiness, the tarry ingredient may be safely doubled in amount, whilst the mercurial may be equally increased. The writer's advice to the student is to adopt this ointment, and use it in every case of sub-acute or chronic eczema which he meets with in the first years of his practice, till he becomes thorough master of the remedy and can alter its proportions to suit the varying stages or varieties of the disease, and the chance is that he will very seldom feel the necessity of resorting to anything else.

As a rule Coal Tar is preferable to Wood Tar, being less irritating, but many dermatologists prefer Birch Tar (*ol. rusci*), Beech Tar (*ol. fagi*), Juniper Tar (*ol. cedrum*), Pine Tar (*pix liquida*). The new B.P. *Liq. Picis Carbonis* is the official representative of the old *Liq. Carbonis Detergens*, both are saturated alcoholic solutions of Coal Tar. Creosote and Carbolic Acid are preferred by some, but they are certainly inferior. The B.P. *Ungt. Picis L.* is too concentrated. Beta-Naphthol and Naphthaline act somewhat like Tar.

The same rule which guides the student in selecting Arsenic in the treatment of chronic eczema applies equally to Tar and its preparations—i.e., the nearer the case appears to approach to psoriasis, the better will tarry compounds act.

The cases of chronic eczema where Tar is unsuitable are very few, and, as a rule, it may be said that where Tar fails it is because it has been used in a too concentrated form. Hutchinson regards Tar as the one remedy for eczema. If he uses two, they are Tar and Lead; if three, Tar, Lead, and Mercury.

Pastes as mentioned under acute eczema, are equally valuable when employed in the treatment of the chronic affection.

Lassar's Paste may be used as the vehicle for any of the above-mentioned more active remedies.

Unna uses Ichthyol, 10 or 20 per cent., or Sulphoichthyolate of Ammonia, 2 per cent., which may be incorporated with the paste. Ichthyol is undoubtedly a valuable drug. Morris states that, like Resorcin and Sulphur, its antiparasitic qualities are undoubted. It allays irritation, destroys parasites, contracts the cutaneous

vessels, and checks discharge, hence he uses it also in the acute disease.

Pick treats the moist stages of all eczemas by his Salicylic Soap Plaster, the formula for which is 5 parts of Salicylic Acid to 100 parts of liquefied Soap Plaster. When a weaker and more adhesive plaster is required, he mixes 2½ parts of the acid with 20 of Olive Oil and 80 of Soap Plaster. These are spread upon strong canvas, cut into strips, and firmly applied to the moist surface, where they may be allowed to remain undisturbed for several days. The itchiness is replaced by a burning pain, which rapidly disappears. Four days suffice for the first application before removal. Subsequent dressings may remain one week each. Sometimes three weeks may be allowed to pass without change of the dressings.

When the scaly or dry stage is reached, the Sublimate Gelatin is indicated. This is prepared by dissolving 30 parts of pure white Gelatin in water over a water-bath, and evaporating the liquid solution till its weight is reduced to 75 parts; 25 parts of Glycerin and .05 Perchloride of Mercury are then added. This is simply painted on after the plaster has been removed, and it can be allowed to remain for days.

Mercurials come in, in chronic eczema, in those cases where the use of strong tarry preparations is doubtful—i.e., in sub-acute cases, where there is not yet much induration, and where redness and irritability lead the physician to doubt the wisdom of using Tar; or they may be combined with Tar to great advantage. They should not be employed where a very large surface is affected. A dilute solution of the Bichloride (1 gr. to 2 oz. water) is an excellent alterative, and may be used with great advantage as a lotion where crusts, scabs, and dried secretion cover over and irritate the already inflamed surface. But perhaps the best of all the mercurial preparations is an ointment of the white precipitate (of the strength of about 20 to 30 grs. per oz.).

Calomel, in similar proportions, often acts well. The dilute Citrine Ointment (1 in 8) or Yellow Oxide is sometimes very valuable. These mercurials may be combined with Zinc, Lead, Tar, or other remedies.

The Unguentum Metallorum, containing Zinc, Mercury, and Lead, is a favourite with many skin specialists. It may be made by mixing equal quantities of the B.P. Benzoated Zinc, Acetate of Lead, and Citrine Ointments.

In very chronic profusely secreting eczemas, great relief and improvement have been obtained by painting over the weeping surface with a solution of Silver Nitrate (30 grs. to 1 oz.).

In chronic very dry eczema, painting over the patches with Blistering Liquid or Liquor Potasse sometimes gives good results; this really causes an acute eczema which can then be treated by milder measures. Morris uses Papain and Chrysarobin in some cases where there is great induration, and

Lustgarten uses the following combination for eczema of the anus and genitals:—Oleate of Cocaine, 2 parts; Lanoline, 40 parts; Olive Oil, 10 parts, applied twice a day, followed by some absorbent dusting powder.

Sulphur, in the form of ointment (40 grs. to 1 oz.), may be tried in very chronic dry cases or Pyrogallic Acid ($\frac{1}{2}$ dr. to 1 oz.), Chrysophanic Acid (15 grs. to 1 oz.), Glycerin of Tannin, Alcoholic Solution of Soft Soap, Boracic and Salicylic Acids, Alkaline Lotions, Eucalyptol, Thymol or Chloral (15 grs. to 1 oz.), Glycerin of Borax or Alum, Resorcin (1 dr. to 1 oz.), Iodol or Iodoform (10 grs. to 1 oz.).

Papan and Pancreatic Emulsion are recommended for the removal of thickened epidermis, and Salicylic Acid, dissolved in Collodion, may be used for the same purpose before applying any of the astringent ointments.

Unna, in seborrhoeic eczema, uses Resorcin. He states that there is no stage, no region, no age, no skin, nor any complication in which this drug may not be used, save in those rare cases of Resorcin idiosyncrasy. He gets the best results from a solution of 10 parts of Resorcin and 10 parts of Glycerin in 180 of strong spirit. Thin layers of cotton wool are soaked in a mixture of 1 part of this solution with 4 of water, laid upon the part, and covered with oiled silk. The horny layer swells, and the Resorcin must be stopped and greasy ointments applied till cure results. Thickening and induration of the skin rapidly yield to Resorcin when employed in this manner.

Hans Hebra uses Glycerinum Saponatum, a very elegant basis for ointments, and one which can be employed in chronic or acute eczema with advantage. It is a combination of Glycerin with an absolutely neutral Cocoa Nut Oil Acid Soap. It is made in two strengths. One contains 80 per cent. of Glycerin and 20 of the Soap basis, the other contains 92 per cent. of Glycerin and 8 of the Soap. Numerous combinations of this substance, with active skin remedies, are made. One of the most valuable is the Zinc Oxide Glycerinum Saponatum and Amylum. It is useful in both acute and chronic eczema, and consists of 78 parts of the 92 per cent Glycerinum Saponatum, 20 parts of Zinc Oxide, and 2 of powdered Starch.

The above are but a sample of the interminable host of eczema remedies, but the physician who selects the older remedial agents, as Lead, Mercury, Tar, and Zinc, will be surprised to find how seldom he will fail to cure with them, and how seldom he will have to seek the newer drugs for the relief of the commoner symptoms or complications.

The Martin's rubber bandage may be used with great advantage in the treatment of chronic eczema of the lower extremities, which so frequently is found associated with the varicose condition of the superficial veins.

A careful adherence to the details already mentioned will enable

the student to treat eczema upon whatever part of the body it may be located, without a special description of the treatment of each of the so-called special varieties.

As an instance of the importance of finding out the cause of the affection in every case where practicable, it may be mentioned that many instances of acute eczema have been observed to follow the handling of various hot-house plants, especially *primula*.

ELECTRIC CURRENT INJURIES—See under Lightning Injuries.

ELEPHANTIASIS.

The treatment should be that of filariasis, the most important being the preventive, which consists mainly in sterilising the water supply and sleeping under mosquito-netting. Blows or contusions of all kinds which are liable to cause abortion of the female filaræ are the chief factor in causing lymphangitis.

During the febrile attacks which come on at the different stages of this affection, the treatment will be that indicated in ague. Antipyretics, like Quinine, Antifebrin, Boiled Fresh Lemons, Arsenic, Iodine, and Diaphoretics, with mild saline purges. The local remedies are very uncertain in their action. The best appears to be the Mercurial Biniodide, made as an ointment and rubbed well into the hypertrophied tissue. It should be used of such strength as will not cause marked skin irritation, and where the situation of the tumour permits of firm continuous pressure being applied some form of elastic bandage may be used, and the affected parts placed in a position of absolute rest. At the same time they should be so elevated as to ensure free circulation. (See also under Chyluria.)

In advanced forms of elephantiasis, accompanied with great hypertrophy, these remedies are ineffectual. Blistering, Electricity, Mercurialunctions, digital compression of the main arteries, and even ligature of the chief blood vessel, though sometimes followed by great improvement are generally powerless to remove the hypertrophied tissue. If the leg be the part affected these means may be continued for a long time, and by their use combined with the continuous application of the elastic or India-rubber bandage, amputation may be avoided.

Where the scrotum is affected the only satisfactory method of dealing with the tumour is to dissect out the penis and testicles with the spermatic cords, and remove the entire tumour with the knife without attempting to form any flaps.

Tumours, weighing as much as a hundred-weight have been thus removed, and the patient after a few months has been completely restored to health. By the skilful employment of numerous good assistants, and the judicious use of Esmarch's bandage, the operation may be rendered as safe as an ordinary amputation and almost bloodless.

In some desperate cases penis and testicles must be sacrificed by dissecting out the patient from the enormous tumour.

EMPHYSEMA OF THE LUNG.

In the majority of cases of emphysema coming under notice, the treatment will mean the treatment of the disease which has produced the emphysema. Bronchitis, acute or chronic, pertussis, asthma, and other diseased conditions of the pulmonary organs associated with prolonged or violent expiratory efforts or coughing are the direct cause of the complaint whose management is now under consideration.

It will, therefore, be for the most part useless to think of checking the progress of the emphysema in the presence of a chronic bronchitis. In the treatment of a chronic bronchial catarrh, with this object in view remedies which render the sputum more liquid and less adhesive should have the first place; secondly, remedies should if possible, be used at the same time with a view to prevent all unnecessary coughing.

Thus in the various forms of dry bronchial catarrh, especially in the variety observed in those whose occupations compel them to breathe air charged with fine dust the incessant attempts at the expulsion of the irritating particles lead to the establishment of pulmonary emphysema of a severe type. The cough remains after the patient has ceased to breathe the irritating atmosphere, and it is out of proportion to the amount of bronchial inflammation present. The use of a stimulating expectorant, like Iodide of Potassium or Apomorphia, combined with Morphia, is of the greatest service in such cases. The treatment of the various forms of bronchitis is already mentioned under Bronchitis (see page 101), and need not again be enumerated.

Very often the physician will meet with patients whose lungs are much involved with emphysema; nevertheless they suffer no inconvenience except when labouring under an attack of bronchial catarrh. In such cases the greatest relief follows the judicious use of expectorant medicines.

The question, however, of great importance is whether anything can be done to remedy the emphysema in the intervals between the bronchial attacks. There are grounds for regarding the starting point of the lesion in the air vesicles as a degeneration. This being so, remedies which will have a contra effect will of necessity be of service. Foremost amongst these will be improved hygienic conditions and everything that will tend to raise the standard of health and as the emphysema itself tends to leave the patient very susceptible to attacks of bronchial catarrh, every means to prevent these should be persisted in as change of climate wearing of respirators, &c. Prolonged muscular exercise and athletic exercises must be avoided; indeed, everything which causes dyspnoea must be forbidden.

The excretory organs must be stimulated by gentle purgatives and active open-air exercise. The digestive functions should be improved when possible by attention to diet and tonics. The condition of the blood may be altered for the better by a course of Arsenic or Iron, or both. Arsenic is undoubtedly the best drug which we possess for the treatment of emphysema. It must, however, be given for a long time with great regularity and the dose need not be large in order to obtain the best results—2 or 3 minim doses of Fowler's Solution with each meal.

Next to Arsenic will come Cod Liver Oil and Iodides. The Iodide of Potassium has the great advantage of being one of the most valuable of expectorants and anti-asthmatics, and at the same time it acts as an alterative and stimulates the entire glandular system. It may be given in combination with the previously mentioned remedies, or in courses of a few weeks' duration, and alternating with them.

Various remedies are recommended for the breathlessness, but as a rule only those are of value which act upon the bronchial irritation nearly always present. Thus of inhalations, Oxygen, Eucalypti Spray of Vin. Ipecac., Turpentine, Eucalyptus, Iodide of Ethyl, and the whole list of expectorant medicines internally, especially *Grindelia*, have been tried.

Depressing expectorants are injurious in the majority of instances, as they interfere with the appetite, and may seriously tell upon the dilated heart, with its thinned walls. Their use should be occasionally suspended during the treatment of the chronic bronchitis present.

Attempts have been made from time to time, to treat emphysema independent of the affections from which it has arisen, and the treatment by compressed air has been followed with satisfactory results in some cases. This is carried out in various ways.

(1) The patient is made to inspire condensed air and to expire into rarefied air. The pressure exceeds the ordinary atmosphere by about $\frac{1}{2}$. The inspiration of the compressed air causes more oxygen to enter the alveoli, whilst the expiration into rarefied air ($\frac{1}{2}$ less pressure than ordinary) causes more carbonic acid and residual air to leave the air vesicles. There is, therefore, an unusually brisk and complete exchange of gases and an increase in the respiratory movements, which it is affirmed produce or lead to increased elasticity in the pulmonary tissue. The treatment must extend over several weeks.

(2) It is found in practice to be much more satisfactory to cause the patient to sit and breathe for a couple of hours daily in a chamber, the atmosphere of which has been gradually compressed to the extent of about $\frac{1}{2}$ to $1\frac{1}{2}$ atmospheres.

This atmospheric chamber or compressed air bath in a short time (according to Williams) causes the patient to breathe much easier, deeper, and slower. As the cardiac and hepatic dulness increase, the true vesicular murmur reappears. The vital capacity

increases, whilst the circumference of the thorax diminishes. An air bath of this kind every other day for two months is generally considered sufficient. The general nutrition of the body improves, and digestion is quickened and appetite augmented.*

Inhalations of CO₂ and Oxygen and Ozone have led to no satisfactory results.

In advanced cases of the disease the heart is generally dilated to a considerable extent and the cardiac tonics—Strophanthus, Digitalis, Sparteine, Strychnine, and Caffeine—always afford some relief. A dry climate is the best, but high altitudes are generally not to be recommended.

EMPHYSEMA (General).

The extravasation of the air into the cellular tissue of the body seldom calls for active interference. Unless the accumulation of air becomes so extensive as to jeopardise life by embarrassing the action of vital organs, the case had better be left alone, as absorption always takes place spontaneously in three or four days. Bandaging of the entire body from the toes to the chin has been resorted to. Should suffocation threaten, the skin may be tapped by a Southey's trochar and canula in several places at once, or several incisions may be made with an abscess knife.

EMPHYSEMA.

As soon as the presence of pus is demonstrated in the pleura by an exploratory puncture, no time should be lost in securing its removal. Delay means danger for several reasons, chiefly on account of the risk of the lung becoming so fixed and bound down by adhesions that expansion may never occur. Recent investigations regarding the cause of empyema have thrown considerable light upon treatment. It is now practically established that the common cause of the affection, especially in children, is the presence of the pneumococcus (*diplococcus pneumonicus*) which produces pneumonia. Washbourn, Hale White, and others have demonstrated that this microbe can cause suppuration in the pleural cavity without involving the lung, though the symptoms are almost identical. When the pus drawn off from the pleura shows that there is no other microbe present, a fair prospect of recovery by tapping is to be expected. Where the streptococcus pyogenes and saprophytes are found, as is generally the case with adults, no such prospect offers. Therefore it is clear that a simple drawing off of the pus may be practised in young subjects for several times, and in adults at least once, before resorting to the more serious measure of resecting ribs.

The usual site in the axillary line about the fifth or sixth space

* An excellent account of the various methods of artificial aërotherapeutics may be found in the second Volume of Allbutt's System: it is written by Theodore Williams, and gives the results of the compressed air bath in various diseased conditions.

may be selected, unless some intercostal space reveals marked bulging below or behind this region, when it may be selected. A trochar and canula, or any of the numerous forms of aspirators, may be used. A very convenient form of instrument is a canula to which a fine India-rubber tube is attached through the intervention of a short branch near its collar. The trochar of this apparatus works in the canula like a piston rod, and after both have been inserted into the pleural cavity, the trochar is withdrawn so that its point clears the opening into the branch of the canula to which the tubing is attached. This branch is furnished with a stop-cock. If the free end of the tubing (which should be about six feet in length) be dipped into some antiseptic fluid in the bottom of a basin placed under the patient's bed, and the stop-cock be now turned on, the purulent contents of the pleural cavity may be syphoned into the basin without any risk of air being admitted into the chest.

As much fluid may be removed as will flow spontaneously through the tube without causing symptoms of cough, dyspnoea, or faintness. Should such embarrassments arise the stop-cock may be closed for a time, and they will generally pass off.

The instrument is so made that the trochar cannot be completely withdrawn from the canula, and it possesses this great advantage, that when the latter is blocked up by clots or plugs of fibrin its lumen can be easily cleared by simply pushing back or driving home the trochar and pulling it forward again. It should be thoroughly rendered aseptic by immersion in Carbolic or weak Perchloride of Mercury solution. The patient may lie in bed with the shoulders well propped up by pillows.

Aspiration may be resorted to, but it is not safe to use the hollow needles in tapping the chest, their sharp points are liable to puncture the lung. When the aspirator trochar is withdrawn from its canula, the end of the mount attached to the rubber tube should be rapidly inserted into the extremity of the canula, and the admission of air avoided; this should be done during an expiratory movement.

In using Dieulafoy's instrument in the ordinary way the negative pressure or suction force is very unequal at different stages of the tapping. When the piston is drawn to the very top of the cylinder, and the vacuum thus created is suddenly brought into connection with the column of fluid in the canula by the turning on of the stop-cock, the difference of pressures is so great as to suck shreds of fibrin into the canula which may block it up. The jerky way in which the fluid is thus pumped out is, moreover, liable to bring on paroxysms of coughing or dyspnoea. The writer after the first complete exhaustion of the cylinder (which should always be made prior to the insertion of the trochar and canula) finds it much better afterwards to draw slowly up the piston as the fluid gradually flows into the cylinder. In this way a much more equable negative pressure is maintained than by the ordinary

method of alternately making a complete vacuum, and causing a sudden rush of fluid with great force into the cylinder.

As much pus should be drawn off as can be got away without causing serious embarrassment, and the opening should be carefully closed with a pad of carbolyzed lint secured by strapping.

The method of treating empyema carried out by Bulau is safe, simple, and satisfactory as far as results go. He inserts a wide trochar and canula between two of the lower ribs, withdraws the trochar, and passes into the pleural cavity, through the canula, a full-sized rubber drainage tube. This is fastened *in situ*, and connected by a bit of glass tubing with several feet of rubber tubing which is dropped into a vessel containing sublimate solution. As soon as the drainage tube is lodged well into the pleural cavity, the canula is pulled over it and removed, and nothing left but the tubing. The contents are slowly and painlessly syphoned off without the danger of the admission of air, or the risk of pulmonary embarrassment being created.

Revielod's method is a modification of this (as is Fagge's plan), by leaving the tube in, *continuous* syphonage is permitted till cure becomes complete.

Generally in a short time signs of reaccumulation show themselves, and in the absence of urgent symptoms the physician may try a second tapping with the hope that the pus may not return. Though this hope must have little grounds in the case of adults, nevertheless in the case of children a complete cure sometimes follows the second tapping. When the fluid collects after the second aspiration a free incision must be determined upon.

If there be any evidence of "pointing" the site of the opening will be the point at which the bulging is most prominent. Marshall has shown that this is most frequently in the fifth interspace in front, external to the cartilages—a spot in which it is found that the thoracic parietes are the least protected, and this surgeon advises the opening to be made here whether pointing has occurred or not.

There is much difference of opinion amongst surgeons about the most suitable site for incision, and the matter is not of vital moment. The incision may be made in the sixth or seventh space in front of the posterior axillary line, or in the eighth, ninth, or tenth space behind in the line of the angle of the scapula.

The most dependent part of the pleural sac would appear to be the best to secure thorough drainage, but the lowest part of the sac may be already sealed up by the pleuritic inflammation, and should the surgeon make an incision into the tenth or eleventh intercostal space as advised by some, he may find it impossible to enter the pleural sac.

[Whatever may be the site selected for incision, the surgeon should never omit the precaution of inserting a fine exploring needle at this spot, so as to ensure pus being found immediately *beneath* the wound. The empyema may be loculated, and I have

seen an operator receive an unpleasant surprise on finding that an apparently well-planned incision failed to give easy access to the pus.—A. B. M.]

Upon the whole the following will be found the most judicious line of action. The patient being under chloroform is placed upon his back, and very slightly rolled over upon the sound side.

Under strict antiseptic precautions an incision is made for about 2 inches over the ninth rib at the angle of the scapula till the periosteum is reached. This is divided in the direction of the rib for the entire length of the skin wound, and the periosteal membrane gently raised from the bone by an elevator, after which, by sharp bone forceps, $1\frac{1}{2}$ to 2 inches of the rib is cut out and removed. When all hæmorrhage is stopped, the pleural cavity is opened by an incision parallel to the rib, a pair of dressing forceps inserted to enlarge the wound, and then about 2 inches of stout drainage tube inserted, and after the discharge of pus the wound is dressed with sublimate gauze and a large pad of absorbent wool.

Care should be taken that the tube be so fastened by a shield and string that it cannot fall back into the cavity. It may be necessary to insert the finger into the cavity and explore it, breaking down adhesions and opening up loculi.

In adults the saw or chisel may be required to complete the division of the rib, and to avoid splintering.

Fagge in the case of children inserted the end of a fine rubber tube into the opening, which he made so small as to cause the tube to be firmly grasped by the skin, the other end of this tube he carried beneath the surface of some carbolized liquid in a jar placed beneath the bed. The negative pressure of the column of liquid acting hydrostatically he found to gradually cause expansion of the compressed lung, and rapid cure often resulted.

If no resection be performed, the incision must be made at a higher level and well to the front of the chest, as the ribs lie so close to each other that the opening readily closes and obstructs the tube in the posterior axillary line.

Where the contents of the cavity become putrid, weak injections of Condy's Fluid, Carbolic or Boracic Acids, Perchloride of Mercury, Iodine, Chlorine Solution, Quinine, or other antiseptics have been used. A simple plan, especially useful for children, is to place the patient daily in a Boracic bath, when the little sufferer unconsciously washes out his own pleura. The sudden deaths that have followed the use of the mildest of these injections should make one pause before resorting to their use, and innumerable successes without irrigation show that ordinarily the washing out is not essential.

If the above treatment fails to relieve, and the pleural cavity continues to secrete pus for months, and it becomes evident that delay in healing is owing to the failure of the lung to expand and

the inability of the chest-wall to fall in and obliterate the space because of rigidity of the ribs, there is nothing open for the surgeon but to perform Estlander's operation and excise portions of several ribs. As much as four inches of the third, fourth, fifth, and sixth ribs, with the thickened pleura attached to them, may be removed, and the chest-wall permitted to fall in and obliterate the cavity, after which a cure may be expected.

Delorme has performed a new operation suitable in very chronic empyema where the lung is hopelessly bound down by adhesions and false membrane. He makes a large opening in the chest-wall by a thoracic flap, cures the false membrane on the parietal pleura, and strips off, *from behind forwards*, the thick membrane from the surface of the lung, which immediately expands, after which he replaces the flap by sutures.

It is hardly necessary to say that during the slow-healing process there must be the closest attention to the general health of the patient. Everything that improves nutrition, appetite, digestion, sleep, cough, &c., must be from time to time pressed into the service. Change of air, scene, and climate may be demanded.

Attention should be paid to the position of the patient's body, so as to secure the most thorough drainage; and at first he should be made to lie upon the affected side, so as to ensure that the opening will correspond to the most dependent point.

ENDOCARDITIS.

The treatment of this affection, which is so frequently a complication of acute rheumatism, is to a large extent also the treatment of the rheumatism. In the early stages of the fever much can be done to prevent the development of serious endocardial inflammation. Sibson pointed out the enormous importance of *absolute rest*. A study of the clinical reports of patients so treated showed that endocarditis occurred almost though not quite so frequently amongst them as in those treated without rest. But it also showed that though endocarditis supervened it was *much less* likely to be followed by *permanent* valvular mischief in those subjected to a thorough rest treatment.

These facts prove the great importance of ordering the rheumatic patient immediately to bed as soon as the symptoms of fever and joint trouble declare themselves. Further on in this article, attention is directed to Caton's views on the prevention of valvular disease.

Conflicting opinions prevail about the value of Salicylates in preventing endocarditis. The writer has carefully watched the results of this treatment at the bedside, and has, as far as possible, kept an eye upon the patients afterwards. His experience though it does not lead him to believe that the Salicylic treatment more than appreciably lessens the chance of endocarditis, nevertheless leads him to believe that it will be proved that a larger proportion of the salicylic cases escape the more serious forms of valvular

lesion, if the patients be not permitted to get up as soon as the urgent symptoms are relieved.

Every means that will lessen cardiac activity and relieve pain must have some beneficial action in lessening the risks of cardiac complications, and must have some modifying action upon these complications when already established.

When the physical signs indicate that endocarditis has already supervened, the Salicylic treatment according to the great majority of observers, should be discontinued. The writer has, however, continued its administration in full doses where the pain and fever kept high.

Some authorities speak strongly in favour of the prophylactic action of Alkalies. There is nothing, however, to be said in their behalf. Yeo combines both treatments thus—

R. *Salicin* *ʒi.*
 Potassii Bicarb. *ʒiv.*
 Sodii Bicarb. *ʒiii.*
 Aqua Destil. ad *ʒxii* *misce.*

Et. mist. Signa—One ounce every two hours with an equal quantity of acid mixture.

The acid mixture consists of 24 grs. Sulphate of Quinine, 3 drs. Citric Acid, 1 dr. Tincture of Lemon, and Water to 12 oz.

In the absence of pain and fever, the Salicylic treatment should always be stopped. Absolute rest must be strictly enforced, and the patient should not be permitted to even sit upright in bed. The nurse must insist upon the use of the bed-pan on all occasions.

In place of the salicylates the best treatment now is full doses of Alkalies combined with Opium. 30 grs. Bicarbonate of Potash, with 5 minims of Laudanum, may be given every 4 hours. Should this line of treatment be pursued for any length of time, it will be well to substitute the Sodium for the Potassium salt, owing to the depressing effect of the latter upon the cardiac muscle. Quinine in large doses may be given when the temperature keeps high. At a later stage, stimulants may be demanded. Should the case become grave, Alcohol, Ammonia, and Digitalis may be given in combination, but only when there is evidence of failure of the ventricle. Harm is decidedly done by the haphazard employment of large doses of Digitalis the moment that any cardiac lesion is discovered. Moreover, it has little action whilst the temperature is high. Rarely will the embarrassed condition of the right ventricle call for venesection, though the writer has seen marked relief follow the administration of a smart saline purgative in endocarditis. Aconite in small doses in the early stage is recommended, but it should be discontinued as soon as the pulse falls.

Local applications are of value in endocarditis when præcordial

pain and distress are prominent. The application of a linseed poultice, upon which a little Unguentum Belladonnæ is smeared, is an effective remedy. The extract, rubbed up with Glycerin, may be smeared over the cardiac area. The liniment alone, or mixed with Chloroform liniment, and covered with oiled silk, or the Belladonna plaster may be applied. Leeches may in rare cases be called for, and Dreschfeld uses the ice-bag instead of poulticing.

Often a small blister, kept in contact with the skin above the apex area for a period not exceeding three hours, gives relief to distressing sensations in this region, and quiets cardiac action if tumultuous. The writer has seen acute rheumatism in its earliest stages treated by the late Dr. Harkin, who applied a large blister over the cardiac area (quite independent of the absence or presence of cardiac complications). The result of this treatment, as regards the prevention or occurrence of cardiac complications, will be of great value; at present the number of cases is too small for basing any conclusions upon. The effect upon the heart, temperature, and pains was always striking in those cases under the writer's notice.

Recently, Caton has published a striking report of the success of the prevention of valvular disease by a combination of rest, blistering, and iodides. His method of employing blisters is intended to stimulate the trophic centres by vesicating the skin areas most closely associated with the heart, i.e., the skin between the clavicle and nipple which is supplied by the first four dorsal nerves. Harkin was led to persevere in his method of blistering over the heart upon his own theory that acute rheumatism was in reality an endocarditis; he regarded the heart as a great joint. (The previous paragraph stands exactly as it was printed in 1895.) Caton lays stress also upon the value of absorbent drugs in removing the imperfectly organised material effused into the substance and upon the surface of the valve, and, though he sometimes gives Calomel, his routine is Iodide of Sodium.

Dr Sansom thinks that vesication, by applying the Liquor Epispasticus over the skin of the left axilla, is of service in endocarditis.

In the presence of symptoms suggestive of a thrombus having formed in the cardiac cavities, Ammonia should be freely given in large doses by the mouth, and, if dyspnoea continue with serious symptoms, it may be given also by hypodermic injection. In the absence of urgency, grave symptoms may be combated with the following combination of Bartholow's —

R. Ammonia Carbonatis ℥iij.
Liquor. Ammon. Acetat. ℥vi. misce

Fiat mistura. Capiat cochlearium magnum ex paululo
aquæ sextis horis.

The after-treatment of endocarditis will be best carried out by a course of Iodide of Potassium in small doses, and for a long time rest must be enjoined. From what has been already said, it will be evident that an early return to active exercise or to busy life will probably have a serious determining influence upon the nature and extent of the valvular lesion. Prolonged rest after apparent convalescence will give the patient the best possible chance of escaping without a permanent valve trouble. In the writer's experience, it is not rare to find systolic apex murmurs disappear at this period.

In Ulcerative Endocarditis, in addition to the above measures, hope of success seems to lie in the internal administration of large doses of antiseptics. Sansom strongly insists upon the continuous administration of the Sulphocarbolate of Sodium, in 30 grain doses three times a day, and, at the same time,unctions of Carbolyzed Oil (1 in 5) over the chest and back, morning and evening. He believes that the Soda Salt appears in the tissues as sulphate, the phenol being set free, rendering the tissues antiseptic.

Success has followed the administration of large doses of Quinine, and small doses of the Perchloride of Mercury, or of Arsenic combined with it.

Some cases have lately been reported as saved by the injection of Antistreptococcus serum.

Stimulants and, at a later stage, large doses of Iron preparations, especially the Tincture of the Perchloride, will be indicated.

ENDOMETRITIS.

Rest, in the horizontal position, must be insisted upon in the acute form of the disease. If the attack is the result of any septic mischief, caused by retained placenta, the accompanying metritis and peritonitis often present will call for remedies to relieve pain and reduce fever. Should there be evidence of any retained membranes, clots, or secretions, the uterus should be well washed out with weak Sublimate Solution. In the absence of such evidence, local injections in the early stages are mischievous. Poultices over the abdomen, or warm fomentations, should be constantly applied. The surface of the poultice may be smeared over with Belladonna.

Dudley recommends a mercurial followed by a saline purge, ice to the hypogastrium, and leeches to the perineum and inguinal regions as the best abortive measures.

Pain should be relieved by Morphia suppositories, and it is a good plan to give a little Opium by the mouth at short intervals, say 2 grs. of Dover's Powder every two hours with $\frac{1}{2}$ gr. Quinine. A dozen leeches may be applied round the anus in very severe cases.

After the more urgent symptoms have been combated by these means, hot sitz or hip baths may be frequently used.

Vaginal injections of large quantities of hot water whilst the patient is in the bath or afterwards, are very beneficial as soon as leucorrhœal discharge appears. Proper precautions must be taken to prevent the vaginal tube being passed into the uterine cavity.

Continuous flow by a can and syphon arrangement is better than the intermittent jetting of the ordinary rubber suction apparatus. The temperature of the fluid should begin at about 102° F and be gradually raised to 108° F. About one gallon of fluid should be used at each sitting, and this may be repeated 2 or 3 times a day. A table-spoonful, or double this quantity, of pure Carholie Acid may be thoroughly dissolved in the water.

Where the symptoms become grave, and there is evidence of serious septic trouble no time should be lost in dilating, curetting, and swabbing out the uterine cavity with Iodized Phenol or other powerful antiseptic, after a free irrigation with Sublimate Solution, after this the uterus and vagina should be packed with antiseptic gauze to ensure thorough drainage. Such a procedure is not to be lightly undertaken, as the results are very different from those following the same operation for chronic metritis, but when they are undertaken they should be thorough.

In the treatment of the *chronic* form of the disease constitutional remedies hold a high position. There are few diseased conditions whose successful management entails such a severe tax upon the skill of the physician.

Rest, except immediately after some operative interference, does more harm than good, but moderate rest should be advised during or about the end of menstruation, and during the early period of pregnancy if the condition be not so advanced as to cause sterility.

Every measure calculated to improve the general health and nutrition of the patient must be insisted upon. A most minute and searching examination should be made into the habits, family and previous history, and general condition of the sufferer, before this can be decided upon. Any violation of a health law must be set right before local treatment is thought of. Errors in diet, resting or taking of exercise, evacuating the bowels &c., may be easily set right. Constipation must be promptly and perseveringly treated, and the regular and systematic use of free saline purges preceded by mild mercurials always does good. Appetite, if failing should be aided by Mineral Acids with Quinine. Strumous, syphilitic or other dyscrasie can be met by appropriate remedies, and sexual excesses prohibited.

A prolonged course of Arsenic, Iodide of Potassium, or Iron may be given with advantage after the more urgent or important symptoms have been combated, and these drugs can be given in short alternate courses with great benefit.

During the management of the case the physician will find himself called upon to relieve symptoms, and to prescribe

temporary remedies until opportunity offers to strike at the root of the disease. Pain must be relieved when severe, and this should be done when possible without resorting to narcotics.

Hot water vaginal injections may be freely used and these may be assisted by the hot sitz or hip bath. One or two gallons of water at a temperature of not less than 105° may be made to syphon continuously through the vagina, soothing local irritability and influencing the entire pelvic circulation most beneficially. In the intervals between the use of the hot injections Bromides are of much value in diminishing local sensibility, and their use may be kept up where narcotics would be objectionable. The dilute Hydrobromic Acid, combined with Sodium Bromide and a small dose of Quinine, is a good routine method of relieving the distressing sensations so commonly observed during the course of chronic endometritis. For occasional use Antipyrine (10 grs.) or Antifebrin (5 grs.) often acts like a charm.

Opium, Morphia, Chloral, Codeine, Belladonna, Hyoscyamus, Alcohol, Cannabis Indica, Conium and other sedatives or narcotics may from time to time in emergencies be employed, but in a disease whose nature and duration are so essentially chronic, the habitual use of any of these potent remedies is to be strongly condemned.

Edis recommends counter-irritation by a series of small blisters applied over the seat of pain, and relief may be often obtained by applying upon lint a mixture of equal parts of liniments of Belladonna Aconite, and Chloroform under oiled silk. Plasters of Belladonna and Opium may afford considerable comfort when worn over the back and loins, and over the lower part of the abdomen in front.

Local treatment will consist in first setting right any complication that may be found to exist. Cervical endometritis, when present, should be dealt with by removing all discharge, dilating up the os if narrowed, curetting, and applying Caustics to the cervical canal by means of a Playfair's probe, armed with a layer of absorbent wool. A pin-hole os should be dilated, and treated by Fritsch's or Schroeder's operation.

Pure Carbolic Acid, Iodized Phenol (1 oz Iodine dissolved in 4 oz strong Carbolic Acid) Solution of Permanganate of Mercury, or Perchloride of Iron, Nitrate of Silver, strong Nitric Acid, Chromic Acid, or other escharotic may be applied to the cervical canal. Granular cervix may be treated in the same way. If there be much congestion, engorgement, or inflammation of the lower part of the uterus, a surprising relief often follows the insertion of a large plug of absorbent cotton wool saturated with pure Glycerin, and allowed to remain in the vagina for 24 or 48 hours.

Should the sterilised probe be found to pass easily up into the cavity of the uterus, and its lining membrane be found roughened and hypertrophied, and especially if the endometritis has been known to follow abortion, or to have had its origin in retained

placenta, the curette may be used. The strictest antiseptic precautions must be insisted upon, and the cervical canal should be dilated with great care. In this way, after drawing down the uterus with a vulsellum the curette is made to scrape the uterine walls from above downwards, beginning with the anterior. After the removal of the *debris*, and irrigation, a probe, well covered with wool and dipped in pure Carbolic Acid, Iodized Phenol, or any of the caustic solutions just mentioned, should be used to swab out the interior of the uterus. The uterine cavity should then be carefully packed with antiseptic gauze to ensure complete drainage, and the vagina filled with a tampon soaked in Ichthyol and Glycerin (1 in 10). In mild cases the application of the Iodized Phenol to the interior of the uterus, without curetting, is all that is necessary.

The method of inserting Chloride of Zinc pencils and other powerful escharotics is falling justly into disrepute, as the destruction of tissue following their use is too deep and uneven and impossible to control, and they leave behind dangerous stenosis and injury to the uterus. When it is really necessary to remove the diseased endometrium the more thorough the curetting the less danger and the better the result. Dudley points out the danger of using the dull curette: the sharp instrument should be used and the entire membrane removed. J. Campbell insists also upon the value of the sharp curette used with a firm hand, and he points to the rarity with which the lesions of metritis are confined to the uterus; when plugs of friable tissue appear in the *debris* removed, these will generally be found to come from malignant growths in the uterus.

Recently the intra-uterine application of steam (atmocautery) has been advocated and tried by several in many cases of endometritis, both for its bactericidal, hæmostatic, and caustic effects. Its value as a substitute for the curette is very doubtful and already serious injury has been reported from its unskilful application.

It is of great importance to remember that these operations should not be undertaken at a time close upon the menstrual period. The best time is about nine days after menstruation has ceased. As a rule, one application, or, at the most two, should only be made to the interior of the uterus every month, and rest for several days in bed should be insisted upon after each operation.

The subsequent administration of Ergot—20 minims of the liquid extract, or 1 grain of Ergotin—or 1 drachm of the liquid extract of *Ustilago Maydis* will do much in restoring the uterus to its normal condition.

In the endometritis following gonorrhœa the iodoform gauze method, in conjunction with irrigation by sublimate (1 in 5,000), gives best results.

The plan of dilating the canal curetting, and packing with iodoform gauze in grave cases of pelvic inflammation, arising

from septic endometritis and resulting in salpingitis or peritonitis, has given excellent results, and may save the patient from laparotomy and removal of the appendages in many cases. It may be resorted to in severe gonorrhoeal cases. Baldy states that curettage is positively indicated in every case of acute tubal and peritoneal disease where there is even a suspicion that the infection originated in the endometrium, that is, in the majority of cases.

ENTERIC FEVER—See Typhoid Fever.

ENTERITIS.

The treatment of this affection, which can hardly be regarded as existing as a primary disease, will correspond to the management of a case of acute or chronic diarrhoea or dysentery. (See under Diarrhoea and Dysentery.) Where the condition is obviously secondary to some other affection, its treatment will be referred to under the head of the primary affection.

ENTROPION.

Entropion or inversion of the eye-lids, and *Ectropion* or eversion of the lids, may be considered under the one heading for convenience.

If the *ectropion*, or eversion of the lids, be depending upon a hypertrophied conjunctiva, the result of old inflammation the excision of a longitudinal piece of the thickened membrane will bring the margin of the lid into its normal place. The solid stick of caustic, or the galvano-cautery may accomplish this. Any bands or adhesions of the skin to the margins of the orbit should be freely divided subcutaneously, after which it may be necessary to sew the lids together till the healing process is complete, in order to prevent a recurrence of the eversion.

Plastic operations, with transplantation of skin, may be necessary in bad cases. If the *ectropion* be caused by paralysis of the seventh nerve, ending in the loss of power in the orbicularis, treatment by hypodermic injections of *Strychnine* may be useful. The canaliculus may require to be slit in order to remedy the lacrymal overflow and measures must be taken to prevent destructive inflammation of the exposed conjunctiva.

Senile and spastic *ectropion* may be relieved for a time by bandaging the eye and applying a strong astringent solution to the swollen conjunctiva.

Entropion seldom fails to return after temporary strapping back of the inverted lid, even when the affection is simply owing to spasm. The best procedure is to pinch up a fold of skin close to the margin of the lid and snip it out with scissors, making the removed portion proportionable to the degree of inversion. At the same time, a small fold of the exposed orbicularis muscle should also be removed, and the marginal fibres of the orbicularis, at the

external angle, may also be cut through. The wound will heal without sutures.

Where there is organic thickening, with much trichiasis, a plastic operation will be necessary. Almost every surgeon has his favourite; the object in each case is to alter the direction of the edge of the lid, and, consequently, the direction of the cilia. To accomplish this, it is generally necessary to remove a small strip of the skin of the lid or a piece of the tarsal cartilage, and in some operations a graft of mucous membrane from the lip is required to form a new edge to the lid behind the cilia.

Arlt's operation is performed by deeply splitting the lid in its entire length, and removing a semicircular flap of skin along its margin, after which the edges of the wound are sutured. This turns forward the margin of the lid containing the lashes.

Other operators, as Streatfield and Wells, remove a wedge-shaped piece of the tarsal cartilage in order to secure more complete eversion of the margin of the lid.

Van Milligen's operation consists in splitting the lid, by a free incision in the intermarginal space, for its whole extent. The gap thus formed is kept open by sutures passed through the skin of the upper lid. A linear strip of mucous membrane is then dissected off the internal aspect of the lower lid, and adjusted into the hiatus caused by the splitting incision.

EPIDIDYMITIS—See Orchitis.

EPILEPSY.

The treatment of this affection will embrace the management of the patient (1) during an attack, (2) immediately before an attack, and (3) in the intervals between the attacks.

If the physician should chance to see the patient when the seizure is taking place, he will find that, beyond attention to a few details, his position must be one of "masterly inactivity."

The instant removal of all constrictions about the neck or throat should be seen to, and the patient should be placed flat upon his back if he has not already naturally assumed this position. A soft pillow may be placed under his head, and attention given to the state of his mouth. If the tongue protrudes, a large cork or piece of rubber tubing may be inserted between the teeth to prevent its being injured. Any artificial teeth or food should, if possible, be removed from the mouth.

It is useless to make attempts to restrain the movements by forcibly holding down the convulsed limbs; all that can be done is to watch and see that the patient inflicts no injury upon himself during the clonic spasms. There are, however, some measures which prove useful during a severe epileptic seizure.

Pressure over the carotid artery upon each side, by thrusting the thumbs deeply against the skin at the root of the neck, and making firm pressure backwards, compressing the tissues very firmly between the thumbs and the spine, may sometimes cut short the attack, and it has been said to sometimes prevent a threatening seizure.

Inhalation of the vapour of Nitrite of Amyl often modifies the attack in a marked degree; 5 minim capsules may be broken and the vapour inhaled through the nose. This is also said sometimes to prevent a threatening fit.

For the prevention of attacks in those cases where a warning or well-marked aura is experienced much may be often done. Tying a ligature tightly round the limb where the aura is felt, or irritating the region by pinching, pricking, or galvanism, may put off the seizure.

Where contractions of muscles warn the patient that an attack is coming on, prompt forcible extension of the contracted limb often wards off the convulsions.

Chloroform or Ether inhalations may also ward off convulsions if employed when the aura is felt. Many other means have been discovered and resorted to by patients who experience warnings—thus violent breathing, shouting, jumping, electric shocks, ammonia, and pungent snuff have been utilised by patients who have found their employment to cause postponement of the attack. Counter-irritation to the spot in which the aura is felt, or blistering of the limb above the spot, sometimes prevents further attacks. If any portion of the body is discovered upon which pressure or irritation causes an attack to come on, Brown-Sequard advised counter-irritation to be applied to this region.

The treatment in the intervals between the attacks has been very varied in the hands of different authorities, but there is no remedy equal in its effects to large doses of Bromine Salts. This should be the method employed first in every case of epilepsy, even where only one attack has taken place, as experience proves that every attack of convulsions predisposes to another seizure. After the first fit of epilepsy, or of *petit-mal*, the bromide should be given at once, and persistently continued for years, if the seizures recur. If no second attack happens the patient may be permitted to leave off in twelve months, having previously from the end of the first six months limited himself to one large dose at bed hour.

Different opinions prevail about the relative values of the different bromides. The Potassium Salt is still the most used, and may be given in doses of 20 to 25 grains three times a day after meals for a long time. The Ammonium and Sodium bromides may be given in similar doses. It is often to be found that the symptoms of bromism which supervene after the potassium salt has been given for some time, may be caused to disappear or lessen by substituting the sodium preparation for a time. The

potassium base has a very depressing effect upon the muscular and cardiac apparatus, and should not be ordered in large doses for indefinite periods. It will be found wise to discontinue the use of all bromides for a few days when severe headache, loss of appetite, great muscular weakness, malaise, and impairment of sensations in various regions appear. Gowers states that these symptoms should be met by tonics, and only as a last resource should the bromides be omitted, for this involves a risk of fresh attacks, which are less easily arrested a second time. In returning to treatment again, the writer begins with the dilute Hydrobromic Acid in 30 minim doses freely diluted three times a day. It is a good plan to keep the patient for one month at a time upon 20 grains of a bromide salt three times a day, changing it to another at the end of this period. Thus in turn the bromide of potassium, bromide of sodium, bromide of ammonium, and hydrobromic acid may be administered for four months. The writer believes that he has seen better results from the Bromide of Ammonium when given in the cases of children and very young adults. Some authorities prefer the ammonium salt to the other bromides in *pétit-mal*. Féré finds the Bromide of Strontium is borne in larger doses than the other bromides. In nocturnal epilepsy one large dose should be given at bed-time.

Brown-Sequard insisted upon a mixture of the bromides as giving much better results than any one singly. The following was his favourite combination given *before meals*, whilst *after meals* a tonic was ordered consisting of either Strychnine or Arsenic with a vegetable bitter:—

R.	<i>Potassii Iodidi</i> ℥i.
	<i>Potassii Bromidi</i> ℥j.
	<i>Ammonii Bromidi</i> ℥ij.
	<i>Potassii Bicarbonatis</i> ℥j.
	<i>Tinctura Calumbæ</i> ℥j.
	<i>Aquæ Destillatæ</i> ℥vj. <i>misce.</i>

Fiat mistura Signa—"A tea-spoonful before meals three times a day, and three tea-spoonfuls at bed-time, in water."

Where *pétit-mal* is present he advised the ammonium salt to be increased and the potassium salt diminished, and he stated that patients have taken the above combination for eight or ten years without harm.

There is no practical guide to the amount of bromides which an epileptic can tolerate without inconvenience, but Gowers' rule is a good one—*one drachm per day* meets nearly all requirements. The great secret of success in treating epilepsy by these drugs

depends upon regularity and perseverance in the dose. Chloral added to the bromide enables the physician to diminish the large doses, and, as Seguin has shown, the dose should be largely diluted with plain water or an alkaline liquid like Vichy.

This treatment should be persevered in for two years after the last attack, and should, if possible, not be interrupted even for a single day. At the end of two years the dose may be diminished to 20 grs. daily for another year.

Fere's plan is to begin with 1 drachm of bromide of potassium *per diem*, and to increase it gradually by half or 1 drachm in each year until it reaches 4 drachms of the potassium, or 5 drachms of the strontium salt.

Recently many reports favourable to Bromipin or Brominol have appeared. This is a compound of Bromine with Sesame Oil. It is prepared in two strengths (10 per cent Brominol and 33½ per cent). A dessert-spoonful of the weaker preparation may be given three or four times a day. The stronger preparation may be given in capsules. It is a very valuable drug to alternate with the alkaline bromides.

R Brominol. (33½ per cent.) ℥ii.
 Pulv. Acacie ℥j.
 Chloroformi gl. xvij. misc., et adde
 Aquæ Destil. ad ℥vj.

℞. mistura. Cpt. ℥ii. ter in die ex aqua.

This dose of 2 drs. is equivalent to 20 grs. Bromide of Potassium.

The acne produced by large doses of the bromine salts is prevented or modified by combining Arsenic with them; rarely does the anaesthesia of the palate and pharynx give any trouble.

Richet has proved that the dose of bromides may be reduced to a half if salt be omitted in every possible way from the food. Bechterew insists upon the wisdom of always giving Adonis Vernalis with these drugs, but often in heart cases Digitalis may be advantageously substituted.

The bromine treatment will be found to fail completely in a variable percentage of cases. In our present ignorance there is no method by which such cases can be recognised till the drug is tried. Probably such examples of the disease will be found to belong to a separate group, with totally different causation and pathology. Where a sufficient trial proves the failure of the bromides, the next remedy worthy of a trial is Belladonna or Atropine. Troussseau got good results from this drug when used over periods of one or two years. The green extract of Belladonna may be commenced in doses of ¼ grain in pills, given three times

a day, and this dose may be increased to $1\frac{1}{2}$ grs. 10 minims of the B.P. tincture may be given, or 1 to 2 minims of the official solution of the Sulphate of Atropine may be administered three times a day.

When belladonna also fails, the following list may be tried in the order in which the remedies are named—Borax, in the opinion of Gowers, is the most effective drug after failure of the bromides, in doses of 4 to grs. ter die; Salts of Copper, Silver, Zinc, Gold, Arsenic, Phosphorus, Cerium, Nickel, Lithium, Osmium, Boron, Sodium Chloride, and Nitrites.

Of the Copper Salts, the Ammonio-Sulphate is the one recommended by Brown-Sequard; $\frac{1}{2}$ gr. in pill three times a day will be a fair dose to begin with. It should not be continued beyond three or four months at a time.

Silver Salts have produced very good results in both forms of epilepsy, but serious permanent staining of the skin has so often followed their administration, that they must be given with caution, and on no account should their administration be continued for a longer period than eight weeks, and even then some discoloration may be produced. The nitrate in doses of $\frac{1}{2}$ grain, or the oxide in doses of 1 grain, may be given three times a day in pills.

Gold Salts have been substituted for Silver; they seem to be of more use in cases associated with structural brain lesion. The Chloride of Gold and Soda may be given in doses of $\frac{1}{16}$ gr. ter die.

Zinc Salts have been much used in the treatment of epilepsy, and their administration is not attended with the serious drawbacks attending the use of silver or copper compounds. The Bromide of Zinc may be given in doses of 5 grs., in water and glycerin, four times a day. It may be combined with other bromides. The oxide in doses of 10 grs., the sulphate (6 grs.), the acetate (4 grs.), the valerianate (4 grs.), the phosphide ($\frac{1}{2}$ gr.), may be given in the pilular form for long periods. The oxide has especial advantages in epilepsy occurring in children, and the valerianate in cases associated with hysteria. The action of the sulphate is the least satisfactory of the list.

Arsenic has been much praised in epilepsy, but it is very doubtful if any real permanent benefit has followed its use, except as a means of preventing acne, in 5 min. doses with each dose of bromide.

Phosphorus has been used and extolled, but much of the good results obtained from its administration may be fairly attributed to the Cod Liver Oil with which it has been often combined when ordered as a remedy in epilepsy. It may, however, be useful when a strict vegetarian diet has been persevered with for a long time.

Salts of Cerium (3 grs. of the oxalate), of Nickel (5 grains of the bromide in pill or syrup), or of Lithium (30 grains of the bromide

in gouty subjects), have been given with varying success. The latter salt acts like the other bromides.

Osmic Acid, which has been extensively used in obstinate scintica, has been administered in epilepsy in doses of 2 minims of a 1 per cent. solution. Wildermuth gave in intractable cases 15 puls. daily, each containing $\frac{1}{2}$ grain of Osmate of Potassium, with benefit in several cases.

Chloride of Sodium, in doses of 1 to 2 drs., has been followed by some remarkable successes in the hands of Nothnagel and others.

Nitrites possess unquestionable power over epilepsy, but unfortunately their effects are, as a rule, temporary. Thus Nitrite of Amyl, as already mentioned, will shorten the status epilepticus, will cut short the convulsions, or will prevent the seizure, in many cases completely if inhaled in time, as soon as an aura is experienced.

Similar effects may be produced by Nitroglycerin, in doses of 2 minims of a 1 per cent. solution, and the effects are more lasting, and this drug can be often advantageously combined with the bromides.

The Nitrite of Sodium has been given with benefit in *pelit-mal*, in doses of 1 grain four times a day in solution.

Where syphilis has been known to exist in a patient the subject of epilepsy there should be no hesitation in beginning with small doses of the Bichloride or Bimodide of Mercury. Afterwards large doses of Iodide of Sodium (30 grs.), three times a day, may be given.

Amylene Hydrate has been much praised by Wildermuth, in doses of 30 grs. thrice daily.

Chloral Hydrate has been given to prevent or modify the seizures, but in the writer's opinion this is a very doubtful procedure in most cases; he has, however, availed himself of its antispasmodic powers in infantile convulsions, probably of an epileptic nature. And, as just stated, it is occasionally of great use in permitting the physician to diminish the amount of the bromides for a time when these disagree.

Antipyrine and Antifebrin have been tried in numerous instances, and have been proved to possess little beneficial influence in epilepsy, except when given in very large doses, and even then the results are often very evanescent, and are sometimes followed by more violent attacks when the action of the remedy passes off. Dupardin-Beaumez strongly recommended antifebrin.

Wood has given strong reasons for believing that a combination of Bromide of Ammonium and Antipyrine will give better results than are to be obtained from either remedy separately, and Potts has published a striking report of 43 cases treated by this combination, the dose being 6 grs. of antipyrine and 20 grs. of the bromide three times a day.

Paraldehyde has been used with some success in place of bromides by H. B. Williams. Its effects soon pass off, however.

Of vegetable substances vaunted for the cure of epilepsy, there is practically no end. Some are, no doubt, valuable adjuncts to the treatment by the metals and their salts, but the great bulk of the list may be safely left aside.

Camphor, Lobelia, Musk, Asafetida, Bryonia, Cocculus Indicus or its active principle (Picrotoxin) Conium, Digitalis, Santonin, Rue, Sumbul, Ignatia, Valerian Turpentine Cannabis Indica, Cypripedium, Galium Aparine, Calabar Bean, Ergot or Sclerotinic Acid, Stimulo, Cocaine, Apomorphine, Caffeine, Codeine, and Curara have all had their advocates.

The above is but a portion of the list of remedies, the glowing accounts of which, in epilepsy and other allied conditions, help to swell the current literature of therapeutics from year to year. Scarcely a single member of the list possesses any anti epileptic virtues, and the use of many of them is fraught with serious danger. Sir W. Gowers perhaps the best living authority upon the action of drugs in epilepsy, after describing the value of the Bromides, Borax, Silver, Zinc, Belladonna, Indian Hemp, Hyoscyne, Nitroglveerin, and Strychnine, states that "the immense number of other therapeutic agents which have been extolled may be passed in silence. Most of them I have tried in vain, as well as a large number of drugs of which nothing has been heard."

Whilst still dwelling upon the treatment of epilepsy during the intervals between the attacks, there are some methods not yet mentioned which have been proved to be worth trial.

Electricity has been used in various ways. A continuous current may be passed through the brain from the occiput to the forehead (about 5 Leclanche elements). Three times as many cells may be used to the spinal column. Static electricity promises to give better results than the continuous current. General electrization, with sparks from the spine, may be tried.

Diminution in the severity and frequency of the attacks has been reported after several weeks application of a weak continuous current to the thyroid gland.

Hypnotism has been mentioned by Liébeault who advises the patient to be hypnotized between the attacks and when in the somnambulistic state suggestions should be made to him that he will not suffer from further attacks. The good results that sometimes follow the interference of so-called "faith-healers" prove the mysterious influence of the imagination in epilepsy, and would justify one in hoping that, when hypnotism is taken out of the hands of quacks and imposters, and scientifically applied in the treatment of disease benefits may be obtained thereby.

Ligature of the vertebral or carotid arteries and removal of the cervical sympathetic have been recommended and carried into practice, but with results that do not at present warrant a repetition of such formidable operations. Much has been written about the benefits to be obtained from surgical procedures in cases where local symptoms point to the possibility of trephining and excising

a portion of the cerebral cortex. Horsley and Gowers, with many other distinguished authorities, advise trephining when the fits are evidently caused by irritability of a known centre, as in so-called *focal epilepsy*, with limited convulsions. Sachs, who records to cases operated upon by Gerster in conjunction with himself, states that "we cannot claim a single decided cure."

Counter-irritation by means of blisters and the actual cautery, applied to the back of the head and neck, has been found to produce benefits of no mean value in epilepsy. A seton introduced into the nape of the neck has been followed by cessation of the attacks for a long time.

Ice to the upper part of the spine, and counter-irritants, like Croton Oil to the scalp have been used successfully by Brown-Sequard. Both agents may be found useful in conjunction with Hyoscine Nitroglycerin, Chloroform, or Chloral in dealing with the status epilepticus.

Diet, though mentioned last, is one of the most important elements in the treatment of epilepsy. The writer has treated several cases of the disease by this means alone and generally found very marked diminution in the frequency and severity of the attacks after putting the patient upon a purely vegetarian diet. After a little, when under the influence of bromides, milk, eggs, and fish may be permitted. It is remarkable that many epileptics, who protest against vegetarian diet at the beginning, can scarcely be tempted to return to animal food after several months' trial of this practice. Gowers sees no advantage in a vegetarian diet, but states that many patients find it wise to abstain from beef.

It is unnecessary to remind the physician that the general condition of the patient must be closely scrutinized, and every violation of health laws jealously guarded against. Over-work, worry, irregularities of every kind, and, above all, sexual excesses, must be prohibited. Ocular, aural, and nasal troubles have been credited with being the cause of epilepsy, and cures are reported after the correction of the former with suitable glasses, but it is possible that any good result might be explained by the impression made upon the patient's mind on being assured that his disease was cured.

The condition known as the status epilepticus is often very grave. Where the temperature is very high, the ordinary measures for hyperpyrexia must be resorted to. Ice to the spine may effect the reduction of the fever heat, and at the same time, reduce the excitability of the nerve centres. Bromides generally fail, but they should be tried: 1 dr. of the Potassium Salt, with 30 grs. Chloral, may be given by the rectum, and repeated in 4 or 6 hours. Morphia hypodermically ($\frac{1}{2}$ gr.), Amyl by the nose, and Chloroform may be tried when all these fail. Some authorities give the bromides hypodermically, but this is liable to lead to serious suppuration.

EPIPHORA.

The cause must be treated; thus if the punctum be displaced by ectropion or entropion these deformities should be removed by the operations described under their heading. If a stricture of the nasal duct be present it must be permanently dilated. This may be accomplished by passing a probe down at repeated intervals through the narrowed duct; to cause wide dilatation the probe may be kept *in situ* for a short time. Astringent solutions may be injected after a very large probe has been made to enter.

Should there be much difficulty in passing the probe either canaliculus may be slit up for a portion of its extent. This is best done by inserting through either punctum a fine grooved director into the sac along the canaliculus, and slitting up the canal in part or in its entire length. After this any form of probe, medicated bougie, tent or style, may be employed to keep up dilatation.

Silting, Weber, and others overcome the obstruction by incisions made with variously shaped knives, and the actual cautery and the galvano-cautery have been used with advantage to cause obliteration of the entire lachrymal sac after milder measures have failed.

Extirpation of the lachrymal gland has been practised.

EPISPADIAS

Is generally associated with ectopia vesicæ, and the only treatment of any service is a plastic operation, performed by dissecting a flap from the abdominal surface and two flaps from the groins, with a view to cover in the exposed bladder region. After the cicatrization of these flaps, another plastic operation, as devised by Nélaton, may be undertaken to remedy the epispadias.

EPISTAXIS

Should only be stopped when the bleeding occurs under such conditions as warrant interference. In plethoric subjects and in those suffering from congestive headaches, the discharge gives relief, and measures for its arrest should not be undertaken unless when the flow has already been plentiful. A writer, reported in the *Medical Annual*, gives the fluid extract of *Hydrastis Canadensis* in 10 drop doses as a sovereign *preventive* remedy for epistaxis, especially in children.

In severe and persistent cases such as will be found associated with renal disease, attention must be paid to the general condition, and, in addition the most efficient remedies will be found to be Chloride of Calcium in 20 gr. doses, or Suprarenal Gland Substance, 5-15 grs. repeated every 3 or 4 hours.

By placing the patient upon his back with the shoulders and head moderately elevated and the arms raised as high as possible above the head, whilst pressure is made upon the nostril, most cases will speedily stop bleeding. Should this fail, cold compresses or ice to the temples and occiput, and sinapisms to the calves of the

legs, may be tried. The reflex action following these applications often speedily causes closure of the bleeding vessels through the vaso-motor supply—Hot foot baths and hot water bags to the spine may be useful. Hutchinson states that by placing the patient sitting in a chair with his feet in a deep pail of very hot water the bleeding invariably stops.

When these measures fail, astringent lotions may be applied upon plugs of cotton wool or lint, which should be gently pushed up the bleeding nostril with forceps. In this way Tincture of Iron or solution of Suprarenal Extract, Spirit of Turpentine, concentrated solutions of Alum or Tannin, Styptic Collod, &c., may be used. The writer's method is, however, much better, and he has seldom failed by it in arresting copious hæmorrhage, even when this has been the direct result of injury, as in removing polypi, &c. It consists in drying out the cavity of the nostril with plugs of absorbent wool, and rapidly inserting small masses of the Puff-Ball (*Lycopodium Gigantum*) till the nostril is comfortably distended with the fungus. (See 7th Edition of the author's "Materia Medica and Therapeutics," page 560.) The plugs of this substance may be left *in situ*. They come away in a few days if left to themselves.

Rubber collapsible bags are made, and can be obtained from any instrument maker; after being inserted they are blown up with air, and can be made to exert a uniform firm pressure upon every recess in the nasal chamber. They are cleanly and effective. The writer has, however, discarded them for the Puff-Ball, because the inflated bag, with its dependent tubing and stop-cock, is, as a rule, so unsightly as to prevent the patient for the time pursuing his ordinary avocation. Should the hæmorrhage be far back, one of these bags may be inserted through the mouth, and after inflation it can be pulled forwards by means of its attached tube, brought out through the anterior nares.

By means of the nasal douche, a stream of astringent solution may be made to pass through the nasal cavity and out of the opposite nostril, if the palate be elevated by keeping the mouth wide open. Fresh Lemon Juice is highly recommended as an injection. Hot water may be so employed with great advantage, as in post-partum hæmorrhage. Astringent powders may be blown in by the insufflator. Ergot and other hæmostatics, by the mouth or hypodermically, are generally useless. The writer has never seen them do any good, but they may be tried. The Chloride of Calcium and the Suprarenal Extract are, however, certainly valuable.

Should all these measures fail, there will be no resource left to the surgeon but to plug the nostrils (with a roll of lint) from the posterior nares. This is one of the simplest and least painful of operations in the eyes of the surgeon—till he has tried it. Having once performed it, he will hesitate to repeat or recommend it. It should never be undertaken unless the loss of blood is serious. By

means of a Bellocq's canula, a thin double whipcord or hempen ligature is passed through the nostril, and one end brought out through the mouth. To this end a compact roll of lint, large enough to block the posterior nares, is attached. Traction upon the cord in the nostril hurls the lint tightly against or into the aperture of the posterior nares, where it is held in position by a plug of lint packed into the nostril in front. Over this plug the ends of the cord may be tied so as to render displacement impossible. It is advisable to leave a piece of string attached to the plug behind, this may be left hanging in the pharynx, or from the mouth. By pulling upon it, the posterior plug can be removed at any time through the mouth without difficulty.

Greville MacDonald finds that the erosion or venous rupture which causes epistaxis is almost invariably situated upon the anterior portion of the septum, and can be reached by a speculum and good light, when the galvano- or other cautery may be brought to bear upon it with definite results, or a small anterior plug may be inserted. Every surgeon will agree with him, when he states that posterior plugging is never necessary except in rare cases of post-nasal hæmorrhage. Chian has found a lesion upon the anterior portion of the septum in 70 out of 81 habitual nose bleeders; he also recommends the galvano-cautery. Several authorities touch it with saturated solution of Chromic Acid, and some with a 3 per cent solution of Trichloroacetic Acid.

Where death threatens from loss of blood, Saline Solution should be injected into the cellular tissue, or into a vein, or transfusion should be performed. (See under *Anæmia*, page 40.)

EPITHELIOMA—See Rodent Ulcer.

EPULIS.

Unless the portion of the alveolar process from which the growth springs be entirely removed, the tumour is almost certain to return. A tooth upon each side of the epulis having been extracted, the limits of the incision in the gum may be marked out by two vertical cuts made by a fine saw. Between these points the growth and adjacent alveolus is cut out by sharp pliers. The operation for the removal of epulis, even when it is large, is a remarkably safe one. The actual or galvano-cautery may be used when the epulis is small.

ERYSIPELAS.

Rigid isolation of erysipelatous patients must be insisted upon in all hospitals and where other patients with open wounds are liable to come into contact with them. The disease is spread in those cases where there is no skin wounds or abrasions by the poison finding an entrance through the nasal membrane or by the throat.

The treatment of the affection resolves itself into (1) *constitutional* and (2) *local* measures.

Everything tending to depress the vitality of the patient must be avoided. Bleeding, leeching, and profuse purging—favourite methods of treating erysipelas in times past—are always contra-indicated. A diet of the most sustaining and easily digested food should be given, solid meats being forbidden till fever disappears. A liberal allowance of good soup, beef tea, or chicken jelly, with milk in large quantity is essential.

In severe cases, alcoholic stimulants are always indicated. It is a mistake to give stimulants alone; when possible, they should be incorporated with the food. Thus, whiskey or good brandy may be mixed with the milk (one wine-glassful to each pint or quart); and port wine (one wine-glassful to each pint of beef tea) may be given almost *ad libitum*. The writer has seen harmful results follow the injudicious order to give unlimited alcohol in severe cases. Sometimes the patient takes the stimulant to the exclusion of food; this is sure to lead to serious trouble. This is got over by laying down the rule that the stimulant is to be mixed with the food. Where milk cannot be tolerated, the *Mist. Spt. Vini Gal.* is an excellent food and stimulant. The previous habits of the patient, the stage at which the disease is found when the case comes under the physician's notice, the condition of the heart and vessels, the amount of cutaneous surface involved, and the temperature will give valuable aid in arriving at a conclusion about the amount of alcoholic stimulants necessary. As a rule, very large amounts are well borne, especially in erysipelas following operations on intemperate or irregularly-living subjects. Mild cases will require no stimulants; they do better without them. As a rule, where alcohol is urgently indicated, Strychnine and Ammonia will also be called for.

Before commencing medicinal treatment, one smart saline purge should be administered in order to thoroughly empty the intestinal canal. A Mercurial may be given 8 hours before the saline if the patient be robust, but it should not be repeated. 1 oz. Rochelle or 4 drachms of Epsom Salt may be given in a tumblerful of lemonade.

Of the various drugs recommended from time to time for internal administration there are but a few deserving of confidence. These are in the order of merit:—Iron, Quinine or Bark, Ammonia, Aconite and Sulphocarbolates or Salicylates, and Jaborandi.

Iron, to be of any use, must be given in large doses—30 to 60 minims of the tincture every 2, 3, or 4 hours, according to the extent of local mischief or in proportion to the severity of the constitutional symptoms. The writer has seen it often do good and cut short the affection but he has sometimes found it to fail completely. If there be high temperature, with great prostration, from the beginning, the Iron treatment must be reinforced with

Quinine or Tincture of Cinchona. The best results will not be obtained by combining these drugs before administration. Though it is difficult to explain, the writer believes that by giving 40 minims of the Tincture of Iron every 6 hours, alternating with doses of 4 or 5 grains of Quinine every 6 hours—i.e., a dose of either drug every 3 hours—the effect will be better than if given together.

Should there be evidence of cardiac failure early in the disease, it is unwise to press iron; then teaspoonful doses of the Tincture of Red Bark, mixed with an equal amount of Aromatic Spirit of Ammonia, and a half ounce of brandy every two hours may be given, well diluted with water. Hypodermics of Strychnine will be indicated at a later stage.

Aconite is extolled. It may be given advantageously where at the very beginning there is high temperature, a dry skin and tongue, with a bounding pulse in strong subjects. The dose should be small and should be repeated every hour, and the remedy should not be continued after the end of the second day unless there be a fresh invasion of other regions. The symptoms rapidly yield to this method of using the drug, and mild cases quickly get well. Such patients generally recover rapidly in any case and it is doubtful if real permanent benefit follows the routine administration of aconite in erysipelas.

Sulphocarbolate of Sodium, in doses of 25 or 30 grains, given every 6 or 8 hours, sometimes succeeds where all these remedies fail, especially where there is diffuse cellular inflammation.

Benzoate of Soda, in doses of 30-40 grains every six hours, acts in a similar way, but generally is not well borne; it is also vaunted as a prophylactic. Strumpel urges the value of Camphor in doses of 3 grs. every two hours. It may be given dissolved in *Sal Volatile* with advantage. Belladonna has been recommended; it may be given with Ammonia or Digitalis should the circulation be much depressed.

Podocarpine hypodermically ($\frac{1}{2}$ grain) has been recommended in idiopathic erysipelas, and many very favourable reports of its value have been received during the last few years.

As regards the real use of internal remedies in erysipelas, the way has been cleared up greatly by recent pathological discoveries. It is clearly demonstrated that the disease is caused by the presence of a parasite, and hence the prevailing opinion that internal treatment can only be of use in correcting the poisonous effects of certain ptomaines or albumoses secreted by the streptococcus. This view does not entirely meet the case; it is clear that phagocytosis plays a very important part in recovery, and remedies like iron and quinine probably assist the phagocytes in their work of destruction.

Much has recently been written about the value of Antistreptococcal serum, and at the present moment it is difficult to decide upon its merits; one may safely affirm that it is greatly inferior in

efficacy to the antidiphtheritic serum, and it is really not strictly antitoxic, but bactericidal. The writer saw a crucial test given to the remedy in the case of a young infant at the breast, whose mother, the wife of a physician, developed mild facial erysipelas. The child was instantly weaned and watched most carefully, and as soon as the first signs of a faint, doubtful blush were observed the serum was immediately given in large doses, and repeated twice daily without the least apparent effect in even retarding a fatal issue. The remedy was administered at a stage long before a diagnosis of erysipelas was possible in ordinary cases. It was the dry, freshly prepared serum which was used. The dose of the ordinary fluid serum is 10 to 20 c.c., and it is claimed to be absolutely innocuous. Bond who publishes some marked successes, insists upon the importance of using the serum early.

The pathology of the disease proves the importance and necessity of local antiseptic treatment.

The local treatment of covering the inflamed surface with some harmless or inert substance, to exclude the air and protect the part from variations of temperature, has been practised from the earliest periods.

Of the innumerable methods from time to time suggested, the most popular is that of sprinkling dry flour or powdered starch over the affected part till a thick layer lies evenly upon its surface. This may be achieved by using a common flour dredger.

White lead paint has been successfully employed; it is less likely to be brushed off by friction, and it keeps out the air and is thus supposed to rob the erysipelas cocci of the oxygen necessary for their growth and multiplication. This is not likely; the micrococci grow in chains in the lymphatic vessels and spaces of the corium. Hewson uses an earth-dressing consisting of clay and water. Various other paints are used with the same intention—Collodion, Traumaticine, or B. P. solution of Caoutchouc, Carbolic Oil (1 in 8). Belladonna and Glycerin ointments are also useful by excluding air and preventing the growth of the parasite. The best results are obtained by smearing the part freely over with a mixture of Lanoline and Ichthyol in equal parts, and then enveloping it in salicylated cotton-wool as practised by Nussbaum. He states that it is seldom necessary to continue this treatment beyond three days, as pain, redness, and itching disappear rapidly after the first application.

This glowing account is not verified though many surgeons rely more upon Ichthyol than upon any other local application. Every one can testify to its failure in very severe cases, and to its weakness in moderately severe cases. Notwithstanding this and its filthy messiness, it is probably the best local application we have for erysipelas. It is generally sufficient to smear it over the skin, and also to apply it upon a lint mask without bandage. Koelzer paints on a 2 per cent. solution of Metacresolanytol (a derivative of Ichthyol). An ointment of Sulphate of Iron (1 drachm) and

Lard (2 oz.) is also a very good preparation. Duckworth uses an ointment composed of equal weights of Prepared or Precipitated Chalk and Lard, to which 6 per cent. Carbolic Acid is added, and covers the part with boracic lint. There are several means by which a local attempt may be made to prevent the disease from spreading. Higginbotham's "ectrotic" method consists in painting a strong solution of Nitrate of Silver (1 drachm to 1 oz.) upon the healthy skin around the margin of the diseased spot. The solid stick may be used after moistening the skin with distilled water. The writer has often observed striking results follow the application of Liniment of Iodine when used in this way.

Some surgeons now treat the disease by limiting its margins by the application of strips of adhesive plaster, which by their pressure prevent the spread of the parasite along the underlying compressed lymphatics, while others use the pressure of rubber or elastic bands for the same purpose. Both these plans are uncertain in their results.

Krause's plan is more drastic: he makes a ring of cross hatching by scarifications outside the advancing border of the disease, after which a spray of 5 per cent. Carbolic Solution is played upon it for a couple of hours. The operation is most painful, but is reported as very effective.

Bromine Solution may be used to surround the diseased area, and some surgeons apply it also over the affected surface. Collodion may be painted in a ring around the diseased spot. Carbolic Acid (2 per cent. to 30 per cent.) may be injected with a hypodermic needle into the subcutaneous tissue around the affected region. Salicylic Acid (concentrated solution) is used in the same way by Petersen, and Wilde uses Sulphocarbolate of Sodium Solution (8 per cent.). Resorcin (5 per cent.) has been also injected.

These injections are efficacious, but they are painful, and not entirely free from danger, and the great majority of cases will certainly yield to ointments.

Koch's great remedy is Creolin. He uses the following combination, and covers it over with oiled silk, and believes that decomposition occurs, Iodine being set free:—

R. Creolini ℥i.
Iodoformi ℥iv.
Lanolin ℥x. misce.

Fiat Unguentum. Signa—"To be smeared over the skin or applied upon lint to the diseased spot and beyond its margins, and then to be covered with oiled silk."

Creosote, made into a paste with Kaolin, is smeared over the diseased surface by Marshall. Valette applies a 30 per cent. solution of Perchloride of Iron, which should be well rubbed in

by a swab of lint. Dewey uses a mixture of equal parts of Glycerin and Sulphurous Acid. Rosenbach gets best results from the constant painting of the diseased surface with a 5 per cent. solution of Carbolic Acid in rectified spirit. Turpentine, Picric Acid 10 grs. to 1 oz. Sulphate of Iron 1 to 100, Tincture of Iodine, Nitrate of Silver 1 in 10, Boracic Acid concentrated solution, Perchloride of Mercury (1 in 1,000), Infusion of Digitalis, Permanganate of Potassium 1 gr. to 1 oz., have been used. As a rule, lotions are unsuitable in erysipelas where the skin is unbroken. Dry heat is essential, variations of heat and cold are certainly to be avoided, and poultices are, generally speaking, very harmful, unless to relieve the tension caused by the suppurative process.

In the great majority of mild cases, the best treatment will be to cover over the surface with Flour, mixed with half its weight of Boracic Acid, apply a thick pad of absorbent wool, and elevate the part affected. Seldom will there be any necessity for using a single member of the above formidable host of remedies. In erysipelas of the head and face, there is much inconvenience caused by the usual mask of lint, with flour and boracic acid underneath, the ointment, composed of equal parts of Ichthyol and Lanoline, leaves nothing whatever to be desired in such cases. It may be freely smeared on the face and scalp several times a day. Ichthyolised Collodion is preferred by some. Renoy's abortive treatment consists in circumscribing the affected region by applying a band or circle of a syrupy liquid, consisting of 3 parts of Ichthyol to 10 of a carefully prepared fresh Traumaticine. Over the affected part itself, inside the traumaticine and ichthyol application, is smeared an ointment consisting of equal parts Vaseline and Ichthyol. This is perhaps the best all round local method of treating severe erysipelas.

Pain and smarting may be relieved by smearing over the part with a paint composed of 1 oz. of Extract of Belladonna, rubbed up with 4 oz. Glycerin, when these symptoms have not yielded to the Ichthyol Ointment.

The cellulæ-cutaneous and diffuse cellular erysipelas are to be treated in the same way. Stimulants and nutritious concentrated liquid nourishment and free ventilation must be insisted upon. The local treatment, as described, should be carried out, and, as soon as tension is observed, hot Charcoal poultices and free incisions may be resorted to, after which the suppurating wound may be treated with weak lotion of Corrosive Sublimate.

In erysipelas affecting the nose the Ichthyol cream may be applied freely with a brush thrust up the nostrils, and these cavities should be washed out every 4 or 6 hours by syringing with saturated Boric Solution. The throat and larynx when affected call for urgent relief by scarification or free incisions. In the case of children, and even in adults, where there is much swelling or œdema, tracheotomy may be the only means at the disposal of the surgeon to save life.

ERYTHEMA.

Under this heading are included by most writers a variety of affections. Their differentiation is not, however, a matter of much importance, as they mostly tend to get well if left alone, and their treatment, therefore, is comparatively simple.

The cause of the erythema should be found out, and remedied when possible. This is essential in chronic or oft-recurring attacks.

Dyspepsia and gastric catarrhal conditions are answerable for many of these cases, and the state of the stomach and its digestive powers must be carefully remedied by appropriate treatment. (See under Dyspepsia.)

The erythema so common after eating shell-fish, pork, salt meats, &c., and commonly called urticaria, is generally found to cease after the offending article of food is discovered and discontinued. The urticaria or erythema following the administration of iodide of potassium, cubeb, copaiba, or turpentine soon ceases when these drugs are stopped. Should the affection appear without obvious cause alkalies, combined with bitter tonics, may be tried first. 30 gr doses of Bicarbonate of Soda or Potash, with 10 grs. of Carbonate of Bismuth, in half an ounce of infusion of Chiretta is an excellent combination. The writer's favourite mixture in such cases is the following :—

R. *Liquoris Magnesi Carbonatis* ʒx.
 Tincturæ Rhei Compositæ ʒiiss.
 Glycerini Purificati ʒss. *misce.*

Fiat mistura, cujus capiat cochlearium unum amplum ter in die horis duas post cibos.

If this be insufficient to cause mild purgation, one dose (2 to 4 drs.) of Sulphate of Magnesia should also be given each morning, in a tumblerful of Potash water.

Small doses of Tartarized Antimony seem to exert some specific action upon erythema or chronic urticaria, and cases are occasionally met with where this agent relieves, after all other plans, both internal and local, have failed. Two grains may be added to the above mixture. Atropine and Ichthyol are both recommended internally by Morris.

By far the best treatment, however, where there is much effusion or exudation, as in acute urticaria, is that introduced by Wright—Chloride of Calcium in 20 gr doses in chloroform water. It rapidly stops wheal formation by increasing the coagulability of the blood and diminishing the tendency to exudations of all kinds.

In severe chronic cases sleep is interfered with and hypnotics are indicated, like Sulphonal and Trional. The new analgesics

sometimes give great relief, and they may be combined with a small dose of Pilocarpine.

Whilst the stomach, liver, renal, or other affections are being treated by appropriate remedies, the local treatment of the case should be attended to.

Beech advises the patient's body linen to be impregnated with starch powder, which should also be freely sprinkled over the bed sheets.

Itching may be relieved by lotions of Alkalies or of Lead when the affection is local, and by tepid baths of Bicarbonate or Carbonate of Soda ($\frac{1}{2}$ lb to 20 gallons) if the general surface is involved. When warm or tepid baths aggravate, great comfort may be obtained by sponging over the body piecemeal with solution of Bicarbonate of Soda (1 oz. to 40 oz. water). Cloths moistened with such solution may be allowed to remain in contact with the itching part. A good lotion, when the Soda Solution fails, is one composed of 1 oz. of strong solution of Subacetate of Lead in 7 pints of distilled or rain water. To this half a pint of Methylated Spirit of Wine may be added. Borax (1 oz. to 3 pints water, may be useful when this fails.

Hydrocyanic Acid (1 drachm to water 15 oz.) may be used upon lint, and covered with oiled silk.

Evaporating lotions often give relief when bathing, sponging, and other means fail.

The following may be applied with a brush or sponge, and allowed to dry:—

R. *Eau de Cologne* ℥i.
 Zinci Oxidi ʒss.
 Liquor. Carbon. Deterg. ʒss.
 Aqua Destillata ʒvii. misc.

Fuit lotio. M. d. u.

Scratching should be forbidden, and variations of temperature, especially exposure to dry heat, always aggravates.

Sometimes the method of applying dry powders, as in the treatment of erysipelas by Flour, Oxide of Zinc, Starch Powder, or Calamine, gives relief.

Erythema Multiforme, Annulare, or Papulatum may be treated in a similar way. Often the writer has seen the ordinary treatment for acute rheumatism (Salicylates or Alkalies) do much good. When bulk form, ointments, such as the official Zinc Ointment, should take the place of lotions.

Erythema Nodosum is often accompanied by severe pain, and calls for special treatment. The elevation of the limbs may give much comfort. Lotions of Lead and Opium may be applied on lint, and covered with oiled silk. The swellings may be painted over with Collodion. The writer has obtained the best results by

enveloping the legs in several layers of warm, absorbent wool, and applying, with moderate pressure, a tight calico or woven bandage from the toes to the knee, whilst the patient is kept in the horizontal position with the limbs somewhat elevated. Should there be any erythema multiforme also present, Salicylic Acid or its soda salt, may be given. In very painful cases a warm poultice smeared over with the green extract of Belladonna, or fomentations of Poppy capsules, may be tried, but as a rule moist heat is not suitable.

Brownlie reports immediate relief by painting the nodes over with a solution of Ichthyol, 1 oz. of which is dissolved in a mixture of 1½ oz. strong spirit and 1½ oz. ether.

Erythema Intertrigo is best dealt with by removing all irritating secretions by gently rubbing the opposing or overlapping layers of skin with an oiled pad of wool or fine muslin, and dusting freely over with Zinc Powder, Fuller's Earth, Starch, or other harmless powder. The erythematous surfaces in fat people should be kept separated by a double fold of lint sprinkled with any of these powders, or the lint may be smeared over with Zinc or Lead Ointment. In infants the intertrigo about the genitals and nates should be covered over with a firm ointment, composed of Zinc Ointment 2 oz. powdered Calamine 2 drachms, and powdered Starch 4 drachms.

For the treatment of Erythema Pernio see Chilblains, page 139.

EXOSTOSIS.

When the peduncle is small the growth may be removed with chisel and mallet, gouge, sharp spoon, saw, cutting pliers, or bone forceps. Sometimes after exposure the knife will be found sufficient when the base is fibrous and not bony. The majority of exostoses should be left alone, unless by their presence they are causing disturbance or producing deformity. Hard or ivory growths upon the cranial bones may be removed by freely exposing their bases, and applying from time to time strong Sulphuric Acid to the peduncle till the death of the exostosis is produced. This result sometimes follows ineffectual attempts at removal of the growth. The galvano-cautery may be tried, but it is of little use save in cases which could easily be otherwise treated.

EXTRA-UTERINE FETATION.

All authorities agree that as soon as an extra-uterine gestation is diagnosed, there is but one safe course to pursue—i.e., to open the abdomen and remove the fetus, whether this be living or dead or suppurating, and with it the placenta and sac whenever this is possible. In those early tubal cases, where there is evidence of recent rupture and hæmorrhage, not a moment is to be lost; the tube is to be sought for and seized, and the pedicle treated as the circumstances demand, after the abdomen has been patiently

sponged out and disinfected as in an ordinary ovariotomy. In the intra-ligamentous cases it may be necessary to pack the cavity with antiseptic gauze and stitch its margins to the original abdominal wound.

In the advanced cases removal of the placenta is generally impossible. The cyst walls should be attached to the abdominal wound so as to completely shut off the peritoneal cavity. The cord having been allowed to bleed so as to reduce the bulk of the placenta, is now cut off close, the placenta left *in situ* and well dusted over with some desiccating powder as Tannin, Sodium Benzoate, or Iodoform, and the entire sac packed gently with Iodoform gauze. The placenta will come away piecemeal or gradually shrivel up. Tait, after cutting the cord off close to the placenta, shut the latter hermetically in the cyst by accurately closing the wound in the cyst walls. The usual practice is to insert a large drainage tube. In making the original abdominal incision by feeling for the spot at which the foetus is most distinctly felt, the placenta may be avoided by a lateral incision and the cyst opened without opening the peritoneal cavity.

This procedure will sometimes ensure the life of the child, and cases are recorded where the operation has been successfully postponed with the view of ensuring the viability of the foetus, but delay is obviously fraught with great danger owing to the increasing likelihood of rupture.

Duncan strongly condemns all electrical, tapping, or injecting methods of treatment in early tubal gestation as uncertain and dangerous. He urges that as the woman's life hangs upon a thread which may snap at any moment, the abdomen should be opened without delay, and this is the advice of most authorities.

Innumerable plans have been devised to cause the death of the foetus. These have for the most part ended in failure, or they have produced rupture of the cyst and the death of the mother, though still, some insist upon the value of the interrupted current. By far the best results have been obtained by making an exploratory abdominal incision, through which the foetus may be removed if the diagnosis prove correct. This line of treatment is also applicable to those cases where rupture has already occurred.

The operation may be performed through the vaginal walls by cutting through into the cyst with the caustery, but by far the best results follow the free abdominal incision: but in those cases where suppuration has already occurred in the sac, and the abscess has pointed or burst into the vagina, a free incision in the vaginal walls will be a safe procedure.

The old methods of tapping the cyst and draining off the liquor amnii of galvano-puncture, and of killing the foetus by powerful electric discharges or injections of narcotics, or by mercurialisation of the mother, are now abandoned.

EXOPHTHALMIC GOITRE See Goitre (Page 328).

FALLOPIAN TUBE DISEASES—See Salpingitis and Pyosalpinx.

FAVUS.

The management of this troublesome parasitic disease taxes to the utmost the patience of the physician. At the beginning, the reader may be reminded that the parasite will not live upon a healthy being. Hence the first indication for treatment will be to find out the "departure from health," and bring appropriate remedies to bear upon it. Pure air, good food, outdoor exercise, and warm clothing, with regularity in living, are essential to the prevention of relapses after the disappearance of the disease.

Local treatment must be vigorously and perseveringly pushed. The first step to be taken is to get rid of the accumulated crusts. This is best done by enveloping the scalp in a cap of lint soaked in Spirit Lotion and covered over with oiled silk. Poulticing and oiling are not satisfactory, but they may be resorted to occasionally for short periods. Epilation and Parasiticides are the main remedies to be relied upon in the tedious struggle against the *Achorion Schouletini*. Blistering is to be pressed into service occasionally, with the view of making way for other remedies to reach the parasite. All the remedies useful for ring-worm of the scalp may be used against favus, and success depends more upon the judicious way in which these agents are used, one after the other than in the persistent use of any one of them. Thus a solution of Sulphurous Acid (1 in 4) may be applied for some time till all the fungus confined to the surface is destroyed. A spray of Sulphurous Acid Gas has given good results. Then a solution of Corrosive Sublimate (1 in 250 of spirit and glycerin) may be applied for a few weeks. Afterwards, Creosote, Resorcin, Carbolic Acid, Salicylic Acid, Thymol, Myrtol, or Oleum Menthae Pip. may be applied in solution in spirit, to which a little Chloroform has been added.

If a greasy preparation or ointment be selected, the scalp should be well oiled to remove crusts, after which a weak ointment of Iodide of Sulphur (20 grs. to 1 oz.) may be well rubbed in. It is the most reliable preparation of its class. The Oleate of Mercury Ointment (5 per cent.) may be used with advantage. Epilation must be resorted to, and the process carried out with care and patience. A weak continuous current applied by means of sponges soaked in Sublimate Solution has been recommended. Zinsen destroys the parasite by using Leiter's tubes charged with water at about 130° F. placed over a compress of weak Sublimate Solution. It is clearly demonstrated that the disease is conveyed from the mouse to the cat and then to children who nurse or play with the affected cat.

The baldness resulting from favus has been remedied by Hodara's method of transplanting hairs.

FEBRICULA.

The physician will constantly meet with cases where the only departure from health that can be noticed will be found in the increased temperature. Such cases may be safely let alone till the cause of the fever declares itself. Simple febricula lasts but a short time (48 hours), and though a satisfactory termination may be safely calculated upon without treatment, nevertheless it is in the power of the physician to give very marked relief to symptoms. The same may be said in those cases where the feverishness is depending upon some other cause.

The patient should get a saline purgative—6 drachms of Rochelle Salt in a tumblerful of lemonade is an efficient, speedy, and agreeable cathartic in such cases. He should be put to bed; he should have light bed clothing, and should only be permitted to take liquid food, as milk, rennet, whey, corn flour, arrowroot, gruel, weak tea, toast water, barley water, &c. The hot, dry skin should be induced to act by diaphoretics and diluent drinks. The following are good combinations for this purpose:—

R. Tinctura Aconiti ℥xxiv.

Aqua Camphoræ ℥vi. misce.

Fiat mistura. Cpt. cochlearium magnum omni hora.

Or,

R. Liquoris Ammon. Acet. ℥ii.

Spiritus Ætheris Nitrosi ℥iv.

Potassi Citratis ℥v.

Aqua Camphoræ ad ℥viij. misce.

Fiat mistura. Capiat ʒss. omni hora.

Lemon Juice made fresh and diluted with hot water or warm barley water may be given *ad lib.*, or the lemon juice may be administered with effervescing potash water or ice.

Antipyretics proper, as Antifebrin, Antipyrine, &c., are not indicated in the treatment of febricula, or for the relief of a simple feverish condition depending upon some passing cause, but they may be used for the relief of headache and backache when very severe.

FEVER.

Under the headings of the different fevers, as Typhus, Typhoid, Rheumatism, Measles, Scarletina, &c., the treatment of the fever state, and of hyperpyrexia, will be mentioned.

FISSURE—See under Anus, Fissure of (Page 52).

FISTULA—See under Anus, Fistula of (Page 53).

FLATULENCE—See under *Dyspepsia* (Page 246).

FRACTURES.

The treatment of fractures is to be carried out on the simple principle of reducing any deformity by bringing the broken fragments of the bone together and securing them in this position by suitable splints, so padded as to overcome any tendency to override or return to their abnormal position.

As soon as a fracture comes under the care of the surgeon, no time should be lost in carrying out these principles. As in the case of dislocations, the great barrier to reduction is the reflex contraction of the muscles, and the sooner the attempt at restoration of the broken fragments to their normal position, the easier will the operation become. The popular idea of the importance of "setting" a fracture as soon as possible after its occurrence is therefore based upon sound pathology.

After the removal of the patient's clothing he should be placed upon a firm hair mattress, and the most gentle and thorough examination of the injured limb should be carried out, after which the surgeon, when all his appliances are at hand, proceeds to reduce the deformity. This should in all cases be achieved without the use of force, by so arranging the position of the limb as to cause the most complete relaxation of all its muscles.

Rough handling may convert a simple into a compound fracture at this stage of the proceedings, hence the great necessity for obtaining the fullest relaxation of the muscles, so that the fragments may be brought accurately together without any pulling or hauling of the limb. This is achieved by an assistant grasping the limb firmly above the seat of fracture, whilst the surgeon makes very gentle steady traction upon the lower part, during which the bones come into apposition, guided by the gentlest pressure of the fingers when necessary.

Having secured accurate adjustment of the bones, a well-padded splint of wood, gutta-percha, perforated tin or zinc is applied on each aspect of the limb. These splints should be so shaped, moulded, or lined with padding as to apply when bandaged an even pressure over the limb. As they are adjusted to the fractured member the gentle extension or traction is to be kept up until the whole is enveloped in a good calico bandage. The use of a few straps and buckles to secure the splints in position before the application of the bandage is a great convenience. Buckles should always rest upon the splints, and not upon the skin. Much skill and experience is required in graduating the pressure of the bandage, which should not be tight, and the seat of fracture should be left free and exposed when possible.

After the bandaging, the limb must be carefully maintained in the position which affords the most complete relaxation of the muscles. The less it is interfered with the better, though careful inspection is to be constantly maintained, lest the bandages may

get tight from subsequent swelling, as gangrene might thereby result.

The surgeon satisfies himself from time to time by passing his finger over the seat of fracture that the fragments are kept in position, and by passing his eye over the entire limb, and contrasting it with its fellow on the sound side, he sees that no rotation or deformity arises.

Cotton wool affords the most tempting padding; it should, however, be very sparingly used. The writer, when in charge of the fracture cases in his house-surgeon days, discarded it entirely, owing to its liability to become lumpy and uneven, and used instead a padding of strips of good old flannel, which answers every purpose perfectly.

In addition to the splints applied to the broken bone, it will be often necessary to use others, with a view of securing complete rest to the joints above and below the fracture, when their movement tends to disturb the position of the fragments. Extension and counter-extension may be required in special cases. Space will not permit of any enumeration of the various special appliances which are used in the treatment of different fractures. Those of them of any use fulfil their purpose only in as far as they carry out the simple indication of ensuring rest and accurate approximation of the fragments of the broken bone, while nature makes good their repair.

Lane has recently boldly advocated and carried into practice the plan of an antiseptic operation, which includes drilling of the ends of oblique fractures of the lower extremity and the insertion of steel screws, which may be left *in situ*, just as in the mending of a chair or table leg.

Plaster, Starch, Glue, Poroplastic Felt, and other immovable casings may be used when the surgeon considers it necessary to permit the patient to move about. They are, if applied from the first, open to the serious objection of hindering inspection at the seat of fracture, but if applied after the progress of repair has been well and satisfactorily started, they are amongst the most valuable adjuncts which the surgeon can command in the treatment of simple fractures.

Continental surgeons have carried the plaster treatment to an extent never thought of by former surgeons. Some thousands of cases of leg fracture have been reported where plaster was applied with various accessory steel and other secondary splints, and the patient permitted to walk about a few hours afterwards and attend to his business. There is no doubt in the writer's mind that this "walking" treatment, as it is called, will meet with sweeping condemnation as its practice becomes more widely tried; at present it is largely in the hands of experts who have acquired much dexterity in properly applying the splints, nevertheless bad results are not rare.

The time during which immobility is to be kept up varies much

in different cases. Less than four weeks suffice in young subjects, but in the old more than twice this period may be necessary. As a rule it may be said that the mistake is sure to be made of keeping the entire limb in a state of absolute rest long after the necessity for such has passed away, to the great retardation of recovery. In most cases gentle massage or kneading, and cautious passive movements, may be commenced after the middle or end of the third week, the splints being again applied. This effectually prevents the formation of adhesions, and greatly increases the vitality of the tissues and minimises subsequent pain and stiffness.

[The advantages of early massage, and early movement of muscles, more especially when the fracture is in the neighbourhood of a joint, have been clearly demonstrated by Mr. W. H. Bennett. The conclusions arrived at by him, after a most exhaustive investigation, in which he had at his disposal the opinions of all the leading surgeons of the United Kingdom, amount to a corroboration of the views of the author, expressed in the previous edition of this work, and which are therefore left unchanged.—A. B. M.]

Where it is available, it is a great assistance to have an X-Ray photograph of the fracture, which shows at once the amount of the deformity, and aids the surgeon in deciding a rational course of treatment.

Compound fractures are to be treated upon the same principles, with the addition of remedies suitable to the condition of the wound. All portions of loose bone are to be removed, the wound most thoroughly cleansed by washing out with antiseptic solutions, and if accurate approximation of the main fragments be not possible, excision of projecting spiculae may be required. Thorough drainage must be secured where there is no hope of rendering the wound aseptic, and the limb so bandaged as to permit of duly inspection and dressing. Amputation or excision of the joint may be called for.

FRECKLES—See *Chloasma* (Page 141).

FRIEDREICH'S DISEASE.

In this malady all drugs hitherto administered have proved utterly useless. Arsenic, Gold Salts, Silver, and many remedies recommended in Ataxia have no beneficial effect whatever.

FROST-BITE.

The affected part, if gangrene or vesication has not already set in, may in most instances be brought to its normal condition, even if white, hard, and insensible, by the judicious application of heat. The heat of the patient's own blood is by far the most effectual way of restoring the vitality to the benumbed part, and the way to secure this is by stimulating the local circulation through friction.

The sudden application of artificial heat may be followed by too rapid reaction, congestion, inflammation or gangrene. The gradual restoration which follows vigorous friction with dry snow is the most satisfactory termination. The part should be afterwards enveloped in fur, dry wool, or flannel.

Where gangrene has already occurred, the surgeon will probably find amputation necessary. As a rule, it will be advisable to use antiseptics freely and to wait for a well-marked line of demarcation if there be but a small bulk of the tissue destroyed. Where the gangrene affects a very superficial film of tissue, Perchloride of Mercury (1 in 2,000) or Permanganate of Potassium (1 in 400) may be freely used. Hermance uses Ichthyol in the slight cases, and where the parts become raw he finds the best application to be Acetanilid Ointment.

The later stages of mild cases can be satisfactorily treated as if they were burns.

FURUNCULUS—See Boils (Page 82).

GALL STONE.

The treatment will, in the first instance, be directed to the relief of the agonising pain produced by the passage of the stone along the ducts. Afterwards measures may be tried with the view of causing the expulsion or the solution of the calculus, or of preventing the formation of new ones.

The pain is best relieved by a hypodermic dose of Morphia— $\frac{1}{4}$ gr. or more, to which 1 minim of the B.P. solution of Atropine has been added. Morphia ($\frac{1}{4}$ grain), Opium (2 grains), Chloral (20 grains), Belladonna ($\frac{1}{4}$ grain of the Green Extract), Antipyrine (20 grains), Antifebrin (8 grains), Ether (30 minims), Turpentine (20 minims), may be given in suitable vehicles by the mouth if nausea or vomiting be absent. The dose may be repeated at intervals proportional to the severity of the pain. Mayo Robson has found relief follow doses of 1 grain of Exalgine dissolved in a teaspoonful of hot water, repeated every 30 minutes for three or four times. The hot bath (water at a temperature of 104°-108° F.) sometimes affords considerable relief. The patient should be kept immersed in the bath, under the surveillance of the physician or of an experienced attendant, till signs of weakness are observed. This treatment may often ward off attacks of pain if resorted to very early. Hot fomentations, local hot packs, and poultices may be tried where a hot bath is not at hand. Copious draughts of hot water alone, or containing Bicarbonate of Soda (20 grains), may be given and may be repeated notwithstanding the presence of vomiting. Yeo advocates the use of these hot draughts, and he recommends 1 dr. Bicarbonate of Soda and 20 grs. Salicylate of Soda, dissolved in 1 pint hot water, to be taken in mouthfuls during the paroxysm.

Emetics often afford marked relief, and the writer has found patients resort to their use without being instructed, having them-

selves discovered the relief which had followed spontaneous vomiting in former attacks. Sulphate of Zinc (30 grains), Ipecacuanha (20 grains), Tartar Emetic (1 grain), Apomorphia ($\frac{1}{16}$ grain hypodermically, $\frac{1}{4}$ grain by the mouth). Mustard (a tea-spoonful in 10 or 15 oz. of water), may be administered. Counter-irritation may give relief in some cases. Should the pain baffie the above list of remedies, Chloroform or Ether inhalation may be resorted to.

Many authorities maintain that there is no drug which gives so much relief in the paroxysm as Olive Oil, in doses of 5 or 6 oz. Some observers state that they never saw the oil vomited (the opposite has been the writer's experience). It may be given with a table-spoonful of whiskey or brandy, and 5 drops of Oil of Peppermint. It is claimed for it that it very often causes the rapid expulsion of the calculi, and greatly increases the flow of bile, and sometimes instantly relieves the pain. Glycerin (in 1 oz. doses) formerly had the same good things said of it. Blum injects into the rectum 15 oz. of the warm oil with good results.

The writer has come to the conclusion that the anodyne treatment of gall stones so generally adopted is quite overdone. He recognises that the paroxysm of pain is somewhat like a labour pain, and is caused by the contraction of the muscular fibres forcing the concretion onwards. The patient should be urged to occasionally try and bear it, with the hope that delivery may be thereby facilitated instead of instantly resorting to anodynes as soon as the pain is felt to be coming on.

In patients subject to attacks of biliary colic the following pom-pom may be left in their hands for use in emergencies till the arrival of the physician:—

- R. *Olei Menthae Pip* ℥ii.
 Spirit. Chloroformi ℥vi
 Spirit. Aetheris Sulph. ℥iv.
 Liquor. Morphinae Hydr. ℥iv.
 Tinctura Cannab. Ind. ℥ii.
 Spirit Ammon. Aromat. ad ℥ii). *misce.*

Fiat mixtura. *Signa*—"A tea-spoonful to be taken with a table-spoonful of whiskey in a wine-glassful of water when the pain comes on. To be repeated in half an hour if the pain continues, and every two hours afterwards till relieved."

Should vomiting continue after the attack, it may be relieved with Lemon Juice and Alkaline Effervescing Mixture, Ice, Bismuth, and Hydrocyanic Acid, or sinapisms over the abdomen. Morphia perules, containing $\frac{1}{4}$ grain each, generally afford marked relief and check retching.

During the intervals between the attacks, the patient should be advised to take free open-air exercise several times daily, and, if possible, to give up sedentary habits or occupation. Diet should be plain, and only in amount sufficient to thoroughly maintain nutrition, all excesses in eating being injurious. Alcohol should be sparingly used, and starchy foods and animal fats avoided. Branton lays stress upon the importance of diluent drinks and the free use of water in the diet.

Alkalies are believed to have a prophylactic effect, and the most popular treatment, and one followed by great benefit, is a prolonged course of Carlsbad water or Vichy water before breakfast. Liquor Potassæ (15 minims), Bicarbonate of Potash (30 grs.), Phosphate of Soda (30 grs.), Castile Soap (15 grs.), Salicylate of Soda (20 grs.), may be alternately tried.

The mineral Acids, especially the Nitro-hydrochloric Acid (30 minims), Iridin (1 gr.), Euonymin (1 gr.), Podophyllin ($\frac{1}{2}$ gr.), Calomel (1 gr.), Green Iodide of Mercury ($\frac{1}{2}$ gr.), purgatives, and so-called hepatic stimulants, have been given with doubtful success with the view of so increasing the amount of bile as to favour the solution of the stone.

Harley's method of expelling gall stones, by manipulation of the abdominal walls by the fingers, may be tried for the expulsion of concretions in the gall-bladder or duct, but it is generally condemned. An operation of the same sort has been recommended under the title of "pumping the liver." It is performed by making firm and quick pressure on the ribs over the liver, after the pressure is made the hands are suddenly withdrawn.

Durand's remedy consisted of a mixture of Ether and Spirit of Turpentine (3 parts to 2); 15 minims of this may be given in capsules, three times a day, during the intervals between the attacks, or every 4 hours while the attack is on. Turpentine alone appears to have some power also of dissolving or causing the solution of small calculi. The writer gives it in capsules (10 minims each) for weeks at a time.

The extraordinary successes said to have followed the administration of large doses (20 to 40 oz.) of Olive Oil require confirmation, though many reports show that benefit may be derived from doses of 5 or 6 oz. As already mentioned the drug is said to have the power of cutting short the paroxysm caused by the passage of the calculus.

Recent literature is full of reports of cures by this method, and the dose is as various as the results; as a rule colossal doses are unnecessary. The rationale of its action is doubtful, but the solvent action of the oil is beyond doubt when stones are submitted to it in the laboratory.

Robson, referring to Brockbank's experiments demonstrating the remarkable solvent action of Olive Oil in 24 hours on gall stones outside the body, states that he has never seen any good result in its employment; but Brockbank points out that a digested

fat appears in the bile as oil, fatty acid, and soap, and all these have marked solvent action on cholesterol, especially the soap. He has also demonstrated that Cholagogues, like Salicylate, Benzoate, and Sulphate of Soda, have no action upon the calculi *in vitro*. Kishkin affirms that the so-called gall stones observed in the motions after Olive Oil are solid fatty salts of lime produced by the remedy.

The writer has seen large numbers of calculi expelled by one heroic dose of Calomel (15 grs.), followed by a large dose of Castor Oil, and he believes that given a case with a history of repeated attacks of biliary colic the best routine treatment is to administer 10 grs. Calomel, followed in 6 or 8 hours by $\frac{1}{4}$ to 1 oz. Castor Oil. If gall stones appear afterwards in the bowel discharge, as he has several times seen, the patient may be exempt from further active treatment, and he should be advised to place himself under a mild course of Carlsbad or Vichy water for a few weeks. If no calculi have been expelled he should be placed alternate weeks upon full doses of hot Carlsbad water, and 30 gr. doses of Salicylate of Soda, with a large dose of Calomel and Castor Oil at long intervals.

Electricity, in the form of the Faradic current, with one electrode over the gall bladder, and the other over the spine, has been tried, with the view of causing vigorous contraction of the muscular fibres of the gall bladder and its ducts, and in a few cases has been found successful. Belladonna is said to act in the same way.

Where the common duct remains obstructed by a calculus, or where the patient's life is rendered unendurable from incessant attacks of biliary colic, or where the gall bladder is found to be distended, or where suppuration, ulceration, or perforation, resulting from calculi, is believed to be present, surgical procedure is not only justified, but may become urgently imperative. The practice of opening the gall bladder early is steadily on the increase, though there can be no doubt that many lives are still lost by a blind persistence in medical treatment.

The operation of *cholecystotomy* is performed by making a vertical incision, 2-2½ inches long, external to the border of the right rectus muscle, commencing one to two inches below the costal arch. This is the usual situation of the tumour if present. The point of the tenth rib is a good guide in the absence of swelling. Having felt the gall bladder by the finger thrust into the wound (after ligature of all bleeding points), its contents are drawn off by the aspirator. The collapsed sac is then drawn forwards, its walls incised, and their margins stitched to the aponeurosis or to the parietal wound, after a thorough exploration and evacuation of any calculi in the gall bladder or ducts. Impacted calculi may be removed with forceps or scoop, or they may be crushed or broken up with forceps, and the *debris* washed out with a stream of warm water. A rubber drainage tube is

inserted into the cavity, and left projecting from the skin wound. After all discharge has ceased, the tube may be removed, and the fistulous opening left to close spontaneously.

This operation is safer and more satisfactory than that of sewing up the incised gall bladder, and returning it within the abdominal cavity, and it is to be preferred to *cholecystectomy* or excision of the dilated gall bladder, as performed by Langenbuch.

Where after opening the gall bladder the ducts cannot be cleared of calculi, *choledochotomy* or crushing of the stone *in situ* in the duct by padded forceps is recommended by Mayo Robson as the next step. Where this fails the duct must be incised and sutured—*choledochotomy*. Teale has successfully broken up the impacted calculi by transfixing them by a stout acupuncture needle. He first tries to crush the concretions between the finger and thumb, and when this fails he resorts to the needle in preference to the crushing forceps.

When the ducts cannot be cleared, and their incision is difficult and dangerous, owing to the depth of the wound, Murphy's operation of *cholecystenterostomy* is the safest, quickest, and most satisfactory. In this way, by means of Murphy's button, an anastomosis between the dilated gall bladder and duodenum may be expeditiously effected, or the concretions may be left *in situ*, and dissolved by a daily injection into the gall bladder of Ether, Oil, Turpentine, or a strong solution of Animal Soap.

These various operations have been frequently performed many times by some operators without a death, and Mayo Robson's opinion is that when confined to the hands of abdominal surgeons the all round mortality will not exceed 5 per cent.

GANGLION.

The small, simple ganglions found upon the posterior surface of the wrist may be best treated by rupturing their walls and squeezing the jelly-like contents into the neighbouring tissues. This is best done by forcibly bending the wrist joint, to make the tumour tense, and then, by applying strong pressure with one or both thumbs, the ganglion can nearly always be ruptured. A smart blow with a blunt instrument may be tried, but this is not desirable. If the ganglion cannot be burst with the surgeon's thumb, it is better to insert a slender knife blade, and incise the wall of the cyst along one side, allowing the contents to escape freely into the surrounding tissues. A mere puncture of the cyst is not sufficient, and is almost invariably followed by recurrence. Pressure by a pad of lint and a firmly-adjusted bandage generally is all that is required.

The writer has caused old recurring ganglions to disappear permanently by folding a coin (a penny) in a piece of lint, applying it accurately over the tumour, and bandaging it tightly for several hours, taking care that the circulation in the fingers is not seriously interfered with. Duplay injects a few drops of Tincture

of Iodine into the cyst without drawing off the contents, and puts on an antiseptic dressing and bandage. Another plan is to pass a carbolyzed silk thread or horse hair through it under aseptic precautions, and permit it to remain for 5 or 6 days.

For small ganglions which persist after milder measures, and for the larger compound ganglions, the only satisfactory treatment is complete resection, under rigid aseptic precautions. In doing this the tendon sheaths will be freely opened up, and even joints in some cases, but this need involve no special risk. Many of these cases, especially those with melon-seed bodies, are tubercular in character, and every particle of the sac wall should, if possible, be removed. The wound is then closed without drainage. Primary union is the rule, and movements are commenced one week after the operation.

GANGRENE.

The cause of the affection is to be first determined; should the case be one of static gangrene, immediate attention to the state of the circulation is demanded. Thus pressure, whether caused by constricting bands (as in herma), by splints and bandages (as in unskilled surgery), or by the pressure of tumours or inflammatory swelling and tension, should be, if possible, at once relieved.

After the removal of the constriction, if the death of the part has not already taken place, it may be averted by the application of dry warmth, elevation of the limb, and gentle friction or massage to empty the large venous trunks.

When gangrene threatens, or has actually set in, the chief aim of the surgeon should be to ensure that it shall be *aseptic*, and of the *dry form*. With this object in view, the affected part should be thoroughly sterilised and wrapped in sterile or antiseptic gauze dressings, covered with absorbent wool, so as to admit of the ready escape of gas or moisture.

If the death of the part is beyond question, immediate or speedy amputation should be performed, as nothing but evil generally follows delay in these cases. The line at which the constriction takes place is an accurate limit to the amount of destroyed tissue.

Traumatic gangrene, if of very limited extent, may be dealt with as an ordinary sloughing sore by antiseptic solutions. If the slough has not separated, its removal may be facilitated by hot poultices sprinkled over with fresh charcoal.

When a portion of a limb is completely destroyed by traumatic gangrene, amputation must follow. It is, upon the whole, safer to wait for a line of demarcation.

In spreading traumatic gangrene, some authorities recommend immediate amputation, without waiting for a line of demarcation, but the weight of authority appears to be against this. It is better to wait for some evidence of a limit to the gangrenous process. This is especially true if the cause is *constitutional*. Exception may sometimes be made in the presence of a cause obviously *local*.

Every effort must be made to keep up the strength and nutrition of the patient, to diminish tension, and to guard against septic poisoning.

In gangrene caused by plugging or by ligature of a main artery, or by the pressure of an aneurism, amputation may be performed at once without waiting for a line of demarcation.

In senile gangrene it will generally be found wise not to interfere till a well marked line is formed the patient's general condition being closely watched and the affected limb enveloped in dry and warm antiseptic dressings, but where the gangrene is extensive and there appears a danger that the constitutional strength is unequal to the drain which must result during the delay of waiting for demarcation, amputation has been successfully performed by Hutchinson and others.

Diabetic gangrene, in suitable cases which show no sign of yielding to diabetic treatment, may get the chance which early amputation affords. Under strict aseptic precautions very encouraging results have recently been obtained. Under such conditions it has been shewn that the stump does not become inflamed, and if the amputation be sufficiently high, the gangrene does not spread.

In Raynaud's gangrene, in the majority of cases, the surgeon should wait for demarcation. Erichsen recommends shampooing and galvanism as preventive measures. (See under Raynaud's Disease).

Hospital gangrene must be promptly met by isolation and thorough ventilation, free stimulation, and large doses of Iron and Quinine. Sloughs should be removed, and the affected surfaces thoroughly irrigated with warm antiseptic lotions, or cauterised with the actual or galvano-cautery, Iodine, Bromine, or Nitric, strong Carbolic or other Acid. The most rigid antiseptic treatment must be carried out.

For internal administration Opium is invaluable, and seems to have a beneficial effect on the progress of the disease, in addition to the relief of pain obtained by its use.

GANGRENE OF THE LUNG—See under Lung.

GASTRALGIA.

The treatment will resolve itself (1) into the management of the case during the attack, and (2) to measures employed in the intervals between the attacks.

Pain may be relieved by Opium, and if very severe by hypodermic injection of Morphia. Cannabis Indica sometimes affords prompt relief. The use of narcotics is, as already mentioned, most objectionable in ailments of a chronic nature where there is danger of the Opium habit being established. In stomach troubles Opium, if given in doses large enough to affect the cerebrum, always interferes with digestion and appetite seriously. Chloral (10 grs.),

Antipyrine (10 grs.), Chloroform or Ether (5 minims), Nitroglycerin (1 or 2 minims of a 1 per cent. solution), Bicarbonate of Soda (45 grs.), Oil of Peppermint (5 minims), Oil of Cajuput (4 minims), Creosote (2 minims), Belladonna (15 minims of tincture), Hydrocyanic Acid (4 minims), may be tried from time to time.

Ewald places most reliance in a sedative combination like that mentioned under Dyspepsia on page 247, and the washing out of the stomach with Chloroform water (1 in 200).

The writer has obtained best results from a large dose of Bicarbonate of Soda (40 grs.), combined with Morphia ($\frac{1}{8}$ grain).

Counter-irritation by mustard, hot fomentations, or even iced poultices may give speedy relief.

Electricity in the form of the continuous current sent through the epigastric region, or of the Faradic current applied to the sympathetic or pneumo-gastric, may shorten the attack without resorting to narcotics.

Sipping of very warm water may be tried—it often aggravates. Acupuncture, or Hypodermics of warm water sometimes afford relief. Chloroform liniment alone or mixed with the liniment of Belladonna or Aconite, sprinkled upon lint and covered with oiled silk, is a valuable method of diminishing sensibility.

For the treatment of the case between the attacks much may be done, and the physician should look out for evidence of some organic or other affection of the stomach. Pure neuralgia of the stomach is a rare disease. Gastritis, ulcer, cancer, dyspepsia, or obstruction of the pylorus may be present, and may be the direct or indirect cause of the attacks of gastralgia. Appropriate treatment (see under the head of each) should be directed to the primary affection. In the absence of any stomach ailment save the repeated attacks of gastralgia, treatment should be directed to the nerve supply of the stomach. Remedies like Quinine, found useful in the cure of neuralgia in other parts of the body, have been sometimes productive of good in gastralgia.

Arsenic in small doses is a valuable drug if given for a sufficiently long period. One minim of Fowler's Solution before meals in a table-spoonful of water should be given for a few weeks, and then 2 minims after meals, and so on alternately for three or four months. Siebert affirms that if no ulcer be present the gastralgia disappears in a few days under arsenic.

Alum is successful in a considerable number of cases when given in doses of about 15 grs. three times a day between meals. It appears to act in gastralgia somewhat like the way in which it relieves painter's colic.

Bismuth in large doses has been given with benefit in some cases, and as much as a quarter of a pound daily has been administered. There does not appear to be any advantage in such heroic doses, as half-drachm doses of the Carbonate will

meet all requirements when given four times a day before meals.

Charcoal in wafer paper before, or three hours after, meals has been known to cause the disappearance of the attacks. It can be used also when the attack is on; the same remark applies to Creosote.

Salts of Silver ($\frac{1}{2}$ gr. of the nitrate or 1 gr. of the oxide) may be given for short periods. Salts of Iron often irritate; the Carbonate (precipitated) in 40 grain doses is the best. Salts of Zinc, the valerianate or the oxide (5 grs.), may be tried. Ergotin has been highly recommended, but the writer never saw any benefit from it. Iodide of Potassium (3 grs.) and Binoxide of Manganese (5 grs.) have been also used. Salicin (30 to 45 grs.), Salicylic Acid (20 grs.), and Resorcin (5 grs.) appear to act like Quinine, and are valuable in cases when the neuralgic history is clear. Minute doses of Strychnine or Nux Vomica are useful adjuncts. Ferments, like Papain and Pepsin, may be used with advantage as they assist digestion, and save some of the work done by the gastric mucous membrane. They may be employed at the time of the acute attacks, and may also be given after or along with meals whilst the patient is undergoing a Quinine, Bismuth, Arsenic, or other course. Allbutt lays much stress upon the curative effect of two or three weeks' complete rest in bed. Scrupulous attention to the quality, quantity, and regularity of diet is an essential point. (See under Dyspepsia.)

GASTRIC ULCER.

The first indication in severe cases is *absolute rest* to the stomach. This is obtained by insisting upon the patient keeping the recumbent position, and being fed by the rectum. Another essential to obtaining absolute rest to the ulcerated organ is the administration of small and repeated doses of Opium, Morphine, or Codeine. The nutrition of the body can be maintained for two or three weeks or longer by nutrient enemata, and these are necessary in all severe cases and whenever hæmorrhage is present.

A nutrient enema should not exceed 5 ozs. at the most; about $3\frac{1}{2}$ ozs. is the most suitable bulk. The ordinary beef tea, milk, egg and salt enema, thickened with starch, is for the most part absorbed, but it is too irritating, and soon sets up an irritable condition of the rectum. It may be much improved by adding a tea-spoonful of Liquor Pancreaticus to each wine-glassful of enema, and a few minims of Laudanum to assist its retention.

Prof. Stewart feeds by the bowel for about 14 days; the enemata are given every 8 hours and passed by a long tube up to the sigmoid, with the patient lying on the left side with the pelvis raised. A fountain enema or funnel, with 5 feet of tubing attached, is used. The enema consists of a heaped tea-spoonful of Somatose, Nutrose, or Plasmon dissolved in the smallest quantity of water.

With this is whipped up one large egg and 4 oz. peptonised milk gruel or two heaped up table-spoonfuls of Mellin's Food; 5 grs. Papan are added. The entire amount should not exceed 8 oz. A little Iron albuminate, is added. Grunbaum gives Ox-serum and milk with Glucose and Pancreatic Liquor.

Leube recommends the injection of finely-divided meat mixed with pancreas. Such an enema may be prepared by mixing 4 oz. finely sliced and minutely chopped meat with 1 oz. chopped pancreas and a large table-spoonful of warm water. This may be injected warm through a wide-nozzled syringe.

The writer has found that the various nutrient suppositories are excellent substitutes for peptonised enemata, and possess many advantages. In all cases of rectal feeding it is essential that the rectum be well washed out daily by a good enema of tepid water.

Where the symptoms are of a mild type—hæmorrhage, severe pain, and persistent vomiting being absent—the patient may be allowed to sit up or to cautiously move about, and feeding by the mouth may be permitted.

Solid food, or nourishment containing hard or coarse particles, must be strictly forbidden. The diet should consist chiefly of milk. This should be administered in very small quantities, and as frequently as possible. The success of treatment will to a very large extent depend upon the care exercised in feeding the patient as described under Cancer of the Stomach on page 118, and it is sometimes surprising how pain and vomiting subside after the patient has been put to bed and fed by small quantities of milk administered by the table-spoon, so as to permit of the liquid nourishment passing through the pylorus directly into the intestine without delaying in the stomach.

Potash water, or lime water, may be mixed with the milk in proportion to the symptoms (acidity, flatulence, &c.) present in each case. As the case progresses, good arrowroot, corn-flour, or other impalpable farinaceous powder may be cooked with the milk. A little later on sago, tapioca, and ground or well-boiled rice may be given. Beef tea, chicken soup, meat juices and jellies, and well-cooked puddings, free from fruit and spice, can be given. Farola and fine oat flour make palatable blanc-mange, which can be eaten with renneted milk. Any food found to cause acidity must be discontinued, the presence of marked acidity having an injurious effect upon the healing process.

As the symptoms disappear and the progress of the case shows that the ulcer is probably cicatrised, solid food must be most cautiously permitted in small quantity, beginning the experiment with well-boiled soft white fish, followed up with young chicken, and finally tender under-done roast beef steak, and chop. Alcohol is as a rule objectionable and sugar should be avoided.

The different symptoms present during the open stage of the ulcer must be met by appropriate remedies. Thus, if hæmorrhage

occurs, in addition to rectal feeding, small pieces of ice should be swallowed and a compress of ice laid over the stomach. Ergot may be given by the bowel, though its value is doubtful. Opium by the bowel is serviceable and rarely will Acetate of Lead and other powerful astringents be beneficial. Tea-spoonful doses of Hazeline may be tried, and Turpentine capsules are useful. Tincture of Iron is of doubtful service, though praised by some. Pulv. Kino Co. is a valuable remedy. (See also under Hæmatemesis.)

The writer has seen life saved in several instances by Chloride of Calcium in 30 gr. doses administered by the rectum.

Saline purgatives, as Epsom Salt to thoroughly clear out the blood which may have passed onwards into the intestines, are strongly advised by Ord, who emphasises the importance of thus getting rid of this source of great irritation. He combines Sulphuric Acid with the purgative, and for the gastric hæmorrhage he does not recommend the usual astringents.

Vomiting must be controlled by Ice internally, and Counter-irritation externally, Bismuth and Hydrocyanic Acid, Creosote capsules, and small doses of Morphia. Where milk cannot be tolerated, potash or seltzer water may be added in equal quantity to it. The writer has seen a mixture of acid buttermilk and potash water often retained where milk was vomited. Rectal feeding may increase the trouble in some cases where there is copious acid gastric juice, and the writer has seen vomiting come on in one chronic case of irritable ulcer every time an enema was given, this is, however, rare. Peptonised milk is disappointing.

Pain is an indication for perfect rest, Blisters, Leeching, Cold Compresses or Warm Poultices, and Morphia. As already mentioned, it is a mistake to give Morphia in large doses in these cases. It will be rarely necessary to give more than $\frac{1}{4}$ grain, in pill or in solution. If the system be brought under the influence of opium, further vomiting is apt to supervene.

Atropine, in doses of half a minim of the B.P. Solution, sometimes checks pain and vomiting where opium is badly borne.

Bismuth, in the form of powder in small doses, acts as a sedative, and relieves pain as effectually as it stops vomiting. If given in the liquid form it may be combined with Hydrocyanic Acid and Morphia, as in the formula on page 241, and a little Cocaine may be added.

In chronic cases Fowler's Solution, in doses of one minim, relieves pain and checks vomiting.

Creosote in capsules is invaluable in such cases. Cannabis Indica, $\frac{1}{2}$ grain of the extract in a minute freshly-prepared pill, may be tried.

Carlsbad waters, by neutralising excessive acid, sometimes afford considerable relief. Any Alkali, in small doses, may be used with the same object in view. The efficacy of Carlsbad

water depends upon its power of diminishing hyper-secretion, as suggested by Pemberton and demonstrated by Jaworski.

Pepsin has been said to have caused death by finding its way directly into the circulation through the open vessels of the ulcer; this is highly improbable. The writer has, however, practically abandoned the use of pepsin for Papan, in 3 gr. doses, combined with Alkalies.

Ord uses the following combination in the treatment of gastric ulcer without catarrh—20 grs. Carbonate of Bismuth, 10 grs. Carbonate of Soda, and 10 drops Tincture of Belladonna three times a day.

When there is much evidence of catarrh he use Brinton's Mixture till the catarrh subsides. The following is his formula:—

R. Potassii Bicarbonatis ℥ii.
Potassii Iodidi gr. xxxvj.
Acid. Hydrocyan. Dil. min. xxxvj.
Infusi Gent. Co. ad ℥vj. misce.

Fiat mistura. Capiat cochlcare mag. ter in die p. p. n.

Blister is of great benefit in chronic cases.

Remedies may be tried in chronic cases with the view of acting as caustics or stimulants to the ulcerated surface.

Nitrate of Silver, in the form of pill, may be given in doses as large as 2 grains. This treatment should not be persisted in for long periods. (See further on for Stewart's plan.) The Oxide may be given in the same way in doses of 3 or 4 grains.

Perchloride of Mercury ($\frac{1}{4}$ gr) and Bichromate of Potassium ($\frac{1}{4}$ gr) have been tried with but doubtful benefit. Nitrate of Uranium, in $\frac{1}{2}$ grain doses, is recommended when the ulceration is believed to extend to the duodenum.

Brinton believed that Opium had a very marked influence in causing the ulcer to heal.

In chronic irritable ulcer the washing out of the stomach has been recommended. The writer has obtained highly satisfactory results from this treatment. The ordinary stomach pump should not be used for this purpose. A soft rubber tube, about one yard in length, should be employed. The end introduced into the stomach should be rounded off like the end of the stomach pump, and a glass funnel should be attached to the other end. With this instrument a stream of fresh warm water can be poured into the stomach through the funnel raised to the level of the patient's face, by depressing the funnel the fluid is easily syphoned off. After the contents of the stomach have been removed a stream of weak antiseptic solution—Chloroform water, Creosote (40 minims to 40 oz.), Boric Acid (2 drs. to 40 oz.), Common Salt and Borax (2 drs. to 40 oz.)—may be passed through the washed organ. Weak

Condy's Fluid answers well. Fourrier has modified the washing-out method by suspending 3 drs. Subnitrate of Bismuth in 15 oz. water, and after 10 minutes he draws off the water, leaving the drug deposited upon the lining membrane of the stomach.

It is needless to say that the utmost gentleness is to be used, and the stomach should not be dilated by the pressure of a high column of the fluid.

Prof. Stewart, after washing out, injects 500 c.c. (17½ oz.) solution of Nitrate of Silver, 1 in 1,000, with the tube just engaging the cardiac orifice. After 2 to 4 minutes the tube is pushed further down, and the solution syphoned off after altering the position of the patient, so that the liquid is made to reach all parts of the viscus. The stomach is then washed out to remove the silver solution remaining, and before withdrawing the tube a tea-spoonful of Subnitrate of Bismuth suspended in 3 or 4 oz. water is injected. These injections are repeated every third day. On the intervening days he injects for 5 minutes 500 c.c. of 1 in 500 to 1 in 250 Alumol with a tea-spoonful of Bismuth Subnitrate.

Bourget practises washing out of the stomach with a 2 per cent. solution of Perchloride of Iron, to which ½ to 1 per cent. Chlorate of Potash is added.

The treatment of ulcer of the stomach may be summed up by quoting Ewald who says, "I know of only one method of treatment which holds out reasonable hopes of success: this is the *rest* treatment, the principle of which is that the stomach is protected from every cause of irritation in the same way as a broken bone is protected by a plaster of Paris bandage. Confinement to bed, nourishment *per rectum*, hot fomentations externally, and internally hot Carlsbad water or solution of Carlsbad salt." He lays great stress upon the importance of Iron and Arsenic in the treatment when the acute symptoms have been combated, and he insists that they are always well borne. The best form for administering at this period is one drachm of a 2 or 3 per cent. solution of the Perchloride in a wine-glassful of Albumin solution (egg albumin 1, water 2) to be sucked through a glass tube. He believes that Arsenic is better given in the form of the acid with Perchloride of Iron in pills.

When (1) a reasonable trial has been given to medical treatment without success; (2) when there is evidence of dilatation dependent on cicatricial contraction in the neighbourhood of the pylorus; (3) when pain returns as soon as the patient attempts to get about; (4) when there have been dangerous attacks of hæmatemesis the patient should be advised to submit to an exploratory incision. In competent hands the risk of this proceeding is exceedingly slight, probably not 5 per cent. Once the actual condition has been determined various operations may be carried out, and within the past five years numerous cases have been recorded with brilliant results.

Complete relief has followed the simple separation of adhesions.

Gastro-jejunostomy has restored many helpless invalids to busy, active lives. Hour-glass stomachs have been rendered functionally active by gastroplasty, or gastro-gastrostomy [I have recently performed the latter operation with the happiest results on a young lady who had been a constant sufferer for 14 years. She states that she is now in perfect health, and can eat ordinary food with impunity. —A. B. M.]

In a few cases the ulcer has been excised; on reasoning from the results following operation for perforation, one would suggest that simple infolding of the diseased area without removal would give excellent results, with a minimum of risk.

Mayo Robson, after an extensive personal experience of these various operations for the treatment of chronic gastric ulcer, estimates the risk at less than 5 per cent., whereas the mortality from the ulcer itself amounts to 20-25 per cent.

When perforation occurs, prompt operation offers the only reasonable hope of life. It is quite true that a few cases of recovery have been recorded under medical treatment, but all competent authorities estimate the mortality under these circumstances as at least 95 per cent.

The best time for operation is the "period of repose" which follows the initial shock. If operation is undertaken within 12 hours after perforation, the mortality is not above 25 per cent. Delay beyond 12 hours more than doubles this mortality. If postponed for more than 24 hours the death rate rises to over 75 per cent.

These figures demonstrate in a very striking manner the duty of the medical attendant when he finds himself confronted with a case of perforation. He must urge, and that strongly, an operation. On his promptness and energy his patient's life depends.

The surgeon opens the abdomen by a median incision. An escape of gas and fluid confirms the diagnosis. The ulcer having been found is infolded, and the perforation closed by a single or double row of sutures. The peritoneum is carefully cleansed by sterilised sponges, occasionally it is found necessary to wash out the cavity with normal saline solution. The abdominal wound is closed with or without drainage, according to the amount of extravasation and the condition of the peritoneum. The patient is fed by nutrient enemata for a few days. Water may be given by the mouth after 24 hours, and peptonised milk after 48 hours; Brand's Essence or beef juice on the third day, and at the end of a week fish and chicken may be allowed.

GASTRITIS.

Unfortunately the term gastritis has been applied by different writers to totally different diseased conditions. If we reserve the term *Acute Gastritis* for those cases of severe acute gastric catarrh, accompanied by serious vomiting, nausea, and depression, the treatment will be that already detailed under *Dyspepsia (acute)*.

After remedying the cause of the gastritis, i.e., alcoholic excess, indiscretion in food, irritant poisons, &c., the organ should be washed out by making the patient swallow a few tumblerfuls of warm water, and then the stomach must get absolute physical and physiological rest. As the duration of the acute affection is so short, rectal feeding will be seldom necessary. In the sub-acute or chronic forms it must be resorted to. Counter-irritation by blisters, sinapisms, dry cupping, iced compresses, or, where these aggravate the distress, hot poultices may be applied.

Opium, by the rectum or hypodermically, or Morphia perules, or dry Morphia placed upon the tongue, is indicated in most cases. Ice may be swallowed in very small quantities at frequent intervals, and, as the nausea and vomiting yield, milk may be given in spoonfuls.

Calomel, 5 or 6 grs. placed upon the tongue and washed down with a spoonful of iced water, may cut short the attack.

Bismuth Hydrocyanic Acid, Creosote, or any of the remedies mentioned under Ulcer of the Stomach as useful for vomiting, may be given.

In acute diffuse phlegmonous gastritis little can be done but rectal feeding and meeting the grave constitutional symptoms as they arise; in the rare localised variety when suppuration has occurred abdominal section as for perforation may be resorted to.

The *sub-acute* variety may be treated on the above lines. (See also under Dyspepsia.) In *chronic* gastritis, the first duty of the physician is to determine, if possible, the cause of the affection. Errors in diet, excesses in eating or drinking, especially in the use of alcoholic stimulants, should be corrected, after which the dyspepsia, vomiting, nausea, pain gastric tenderness, &c., should be treated upon the principles already laid down in discussing the treatment of Dyspepsia.

Ord lays great stress upon the value of Iodide of Potassium in gastric catarrh, administered with some Bicarbonate of Soda. It is, in his opinion, a drug of inestimable value, and speedily removes simple gastric catarrh, and prolongs life in malignant disease.

Ewald urges the importance of Hydrochloric Acid as an *anti-ferment*, alone or with Pepsin, Lavage, and Bitter Tonics, with a dietary selected upon rational principles.

GENU VALGUM (Knock-Knee).

Genu Extrorsum (Out-knee) and *Bow Leg* are deformities owing their origin generally to errors in feeding, to mal-nutrition, and rickets, knock-knee being often caused by too much standing or the carriage of heavy weights in growing and feeble youths. These affections can be, for the most part, successfully treated if the case is seen in the early stage before development of the bones has been established.

The first indication is to insist upon *complete rest* in the horizontal position in bed. The weight of the body must be taken off the yielding ligaments and softened bones for a considerable period.

The nutrition must be improved in every way, and the diet carefully seen to. The various methods mentioned under the head of Rickets should be applied to those cases coming under that category.

Massage of the affected limbs should be performed at least twice a day. Friction and manipulation, with a view of exerting pressure to correct the bending, may be performed by the nurse or patient several times daily.

Bandaging the limbs to suitable splints, selected as sound common sense and surgical or mechanical knowledge may dictate, will bring the deformity back to the normal standard when rest and massage fail. In knock-knee a firm cushion of flannel or wool may be placed between the knees, and both ankles may be bandaged together. Where one knee only is affected, the limb may be strapped neatly and uniformly to a suitable splint, the bony prominences being well protected by suitable padding.

In bow-leg a double-padded splint may be placed between the legs, extending from near the primum to some inches beyond the soles of the feet. To this splint both legs should be evenly bandaged.

It is a good practice to resort to splints, even in mild cases, since their use enables the child to be safely carried or driven out in the open air without the risk of his leaning his weight upon the limbs. Standing should be rendered impossible by the adjustment of the splints. Massage may be performed at night. In severe cases attempts may be made to straighten the limb under Chloroform, and, in confirmed, long-standing cases, osteotomy is the only available procedure. Macewen's operation is the most suitable, and gives the best results in knock-knee. He has performed antiseptic supracondylar osteotomy of the femur over 1,000 times, with only a few deaths. He divides the femur above the epiphysis from the inner side for more than two-thirds of its thickness in a direction parallel to the articular surface, and then fractures the remainder. No ligatures or sutures are generally required, and the dressing may be sometimes left unchanged for a fortnight. The limb is put upon a splint for a few days, after which a plaster bandage is applied for about six weeks. When the wound has been soundly healed, the limb is carefully examined, and should any deformity still remain, it can easily be corrected before the uniting material has become hard and firm.

GLANDERS.

Stimulants, and abundance of concentrated, easily-digested, sustaining food, should be administered in all cases of this serious affection.

The seat of inoculation, when recognised, should be freely cauterised by the galvano-cautery. All swellings and local collections of pus should be freely incised at an early stage, and the cavities, after being syringed, may be well mopped out with Sublimated solution or Creosote and cotton wool on a stout probe.

The free use of antiseptic solutions and inhalations afford the best prospects of limiting the terribly destructive inflammation.

Drugs are of little avail in the acute cases, which are almost always fatal, but of much value in the chronic forms of the disease, in which about half end in recovery.

Recently Mallein (a liquid containing the toxin of the glanders' bacillus) has been injected in 1 min. doses every second day for weeks, and the results lead to the hope that the disease in the chronic form will be found to finally disappear under this treatment.

Sulphocarbulates and Benzoate of Soda are valuable, and may be given in doses of 30 grs. three times a day. Where there is much prostration, large doses of Ammonia are indicated.

Quinine, 5 grs. every four hours, dissolved in 15 minims of the Tincture of Perchloride of Iron, may be given.

Arsenic, Iodides, Carbolic Acid, and Strychnine have their advocates.

Symptoms, as they arise, such as pain, diarrhoea, profuse perspirations, rigors, vomiting, &c., must be met by appropriate remedies. The air of the patient's room should be kept saturated with the vapour of Carbolic Acid, Terebene, or Turpentine, and the greatest care exercised against inoculation of the virus on the hands or faces of his attendants.

GLANDS, Diseases of—See Lymphadenitis and Scrofula.

GLAUCOMA.

It is just possible that the discovery that Eserine or Calabar Bean has a marked tendency to diminish the tension in glaucoma has not been an advantage. Though mild cases of the disease are relieved, and not a few permanently cured, by the free instillation of a solution of Eserine (1 in 250), nevertheless it may mislead the surgeon by giving a transient relief in severe cases, tempting him to postpone radical or surgical treatment till the sight is totally destroyed, and the case placed beyond the reach of art.

The severe pain calls for relief, and whilst awaiting positive evidence for diagnosis, Eserine may be used.

Opium or Morphia, hypodermically, leeching, and warmth to the affected eye, with a sharp purgative of the saline class, will afford very considerable relief. It should, however, always be understood that such measures are not to be relied upon, save as a means of rendering the patient's condition tolerable, till marked increase of tension demonstrates the serious nature of the affection.

Belladonna must not be used from its dangerous power of increasing the pressure within the eyeball.

Of all the operative procedures practised or recommended for the relief or cure of glaucoma, there is none which has yielded such satisfactory results as iridectomy.

Iridectomy, to be successful, should be made by a large wound, partly in the sclerotic, and not entirely in the cornea, and a large portion of the iris, at least $\frac{1}{4}$ of the whole, should be removed up to its ciliary attachments, partly by cutting and partly by tearing.

Sclerotomy, or the making of a wound in the sclerotic, as if an iridectomy was about to be performed, has in many cases been successful. The knife (Graefe's) should be entered about 2mm. behind the corneal margin. It is, upon the whole, a much less satisfactory operation than iridectomy, and often ends in this operation, through prolapse of the iris, which must be removed. It is, however, found in many cases requiring a second operation, that sclerotomy may answer all purposes when the previous operation has been iridectomy.

A number of cases, specially of chronic glaucoma, have recently been treated by removal of the superior cervical ganglion of the sympathetic nerve. The results of this operation have been summed up by Grunert:—62 cases have been reported up to April, 1901, including acute and chronic cases; of these 40 were reported improved, and 22 unaltered or worse; but Grunert says many of these have not been watched long enough yet, and he considers the good results to be over-estimated.

Paracentesis of the aqueous humour from the anterior chamber is indicated in secondary glaucoma.

Hyposcleral cyclotomy, performed by cutting through the ciliary body in an antero-posterior direction by a narrow Graefe's knife, has some advocates.

Where total blindness exists, and the eye is frequently or always painful, enucleation should be done.

GLEET.

In the treatment of this troublesome affection, which almost always has its origin in gonorrhoea, the remedies suitable to gonorrhoea may be tried with a fair hope of success. This is especially true of cases coming for the first time under notice when there is a history of a neglected or badly treated attack of gonorrhoea. Where the disease is of many months duration the ordinary gonorrhoeal injections are worthless, and time need not be wasted in their trial.

Keyes formulates a general law which is a good guide to the surgeon. He states that the nearer a case of chronic urethritis approaches to the acute form in its character the more appropriate are those internal and local remedies which are indicated in the acute disease.

The general health should be improved in every way possible, and complications such as constipation, anæmia, dyspepsia, and oxaluria, should be corrected by appropriate remedies. Stimulants, excessive smoking, sexual intercourse, over-eating and indulgence in articles of food which experience has proved to aggravate or be the cause of the prolongation of the disease, as strong tea, pickles, beer, &c., must be strictly prohibited.

Excessive fatigue is as injurious as spending too much time in bed. Sea-bathing, when the season permits, or cold baths indoors, and moderate open-air exercise, are beneficial in all cases.

Constitutional remedies as tonics, consisting of full doses of Tincture of Iron (15 minims), with 3 grains of Quinine or tea-spoonful doses of Easton's Syrup, often do good. Tincture of Cantharides, in doses of 2 or 3 minims, is a favourite remedy with many surgeons. The writer has no experience of the drug in this disease. He has seen excellent results from tonic treatment, with one dose of Boracic Acid (10 grs.) given at bed-time every night. Oil Gaultheria or Turpentine may be used instead of Cantharides.

The local treatment of gleet is by far the most important, and the number of remedies is almost endless. Nearly every known astringent and antiseptic has been injected down the urethral canal for the cure of this disorder. Where the gonococcus is found in the discharge the new organic Silver Salts afford the best chance of successful treatment.

Decidedly the most successful of all local remedies is the passage of a solid silver or plated graduated sound with a wide curve. Sir Henry Thompson's old-fashioned tapering, solid, heavy bougies are, in the writer's opinion, the best instruments for general use. One of them, well lubricated, should be permitted to glide into the bladder by its own weight. The size selected should be of the full diameter of the urethra; it should be left in situ for a period of a few minutes at first, and this period should be gradually lengthened at subsequent sittings and a larger instrument employed each time till No. 15 (English) is reached. Any lubricant may be used; the writer uses the P.B. Glycerin of Borax. Most cases of gleet will be found to yield to this treatment if carried out for some weeks. Twice a week will be about the best rule for guidance as regards the frequency of the sittings. The advantage of this treatment lies in its freedom from danger when contrasted with the injections of strong astringent solutions. Moreover, it effectually remedies any stricture or narrowing of the urethra which is found so frequently associated with gleet. The persistent use of the solid bougie, in the writer's opinion, will also prevent the formation of stricture.

Nearly every known antiseptic may be smeared upon the bougie if made into a stiff ointment. Special grooved instruments are made for the application of solid ointments, but these are unnecessary, as, owing to the adhesive nature of Lanoline, any substance incorporated with it will adhere to the end or curve of

the ordinary bougie, and may be carried down and left in contact with the diseased area.

Iodoform (30 grains), mixed intimately with 1 oz. ointment of Hazeline, is a valuable lubricant. Carbolic Acid, Resorcin, Nitrate of Silver (5-15 grs. to 1 oz.), Copaiba or Santal Oil, may be used in this way.

Where a more complete local application is required, the drug may be incorporated with a firmer basis, made into bougies, which can be passed down the urethra and left to melt by the heat of the body. Unna's bougies contain (1 in 100) Nitrate of Silver and are made with Cacao Butter and a little Wax and Peruvian Balsam. Antrophores are specially prepared bougies, consisting of Sulphate of Thallin (2 to 6 per cent.). Excellent results are obtained by their use in chronic gonorrhoea and gleet.

In the absence of these, Thallin, Iodoform, Nitrate of Silver, or other drug made into a creamy consistence with Oil, Gelatin, or Mucilage, may be injected through a soft rubber catheter passed down to the seat of the mischief.

The various urethral syringes may be employed to cauterise any part of the canal which is found by Leiter's urethroscope to be diseased. Tiemann's or Harrison's irrigators, Guyon's bullet-catheter, Keyes', Teevan's, or Thompson's prostatic injectors, are the best. 20 grs. of Nitrate of Silver to 1 oz. distilled water is the usual strength, of this 10 to 20 minims may be injected, Cocaine having previously been injected, and the patient should remain afterwards in bed for the day.

The plan of irrigation, as mentioned under Gonorrhoea, gives good results, and the weak Permanganate solution may be used for the anterior urethra, and afterwards for the posterior, and if the disease resist these, Copper Sulphate or Perchloride of Mercury may be tried, or instillations of Thallin (10 per cent.), Protargol (10 per cent.), or Ichthyol (10 per cent.) will be found to speedily bring the discharge to a termination.

Otis treats gleet in the following manner. He first dilates gently the urethra to its full extent, without using force, then a silk *coudé* catheter is introduced just beyond the compressor urethræ muscle, so that the eye lies in the neck of the bladder, then about 8 oz. of fluid injection is introduced into the bladder by a syringe. The patient passes this after the withdrawal of the catheter, thus flushing out the urethra thoroughly.

The first injection consists of one part each of Sulphate of Zinc, Alum, and Carbolic Acid in 2,000 parts. Upon the second day the water is reduced to 1,500, and upon the third to 1,000, and upon the fourth day to 500 parts (1 gr. to 1 oz. nearly). Upon the fifth day Solution of Permanganate of Potassium (1 in 2,000) is used, upon the sixth 1 in 1,500, upon the seventh 1 in 1,000. Afterwards the solution is changed to one of Nitrate of Silver (1 in 1,000) gradually increased to 1 in 100.

If these fail, a few drops of a 5 per cent. Nitrate of Silver Solu-

tion are passed into the deep urethra by the drop-syringe, and when the disease still resists he performs internal urethrotomy.

Of injections for gleet the following may be used. —

- Sulphate of Zinc (3 grs. to 1 oz.).
- Nitrate of Silver (1 gr. to 1 oz.).
- Tincture of Iodine (5 minims to 1 oz.).
- Corrosive Sublimate (1 gr. in 10 ozs.).
- Sulphate of Thallin (5 grs. to 1 oz.).
- Tannin (5 grs. to 1 oz.).
- Creolin (6 per cent.).
- Bismuth (30 grs. to 1 oz. with Mucilage).
- Acetate of Lead (10 grs. to 1 oz.).
- Sulphate of Copper (3 grs. to 1 oz.).
- Iodoform (20 grs. in 1 oz. Oil).
- Eucalyptus Oil (1 in 30 of Oil).
- Sulphocarbolate of Zinc (2 grs. to 1 oz.).
- Permanganate of Potassium (1 gr. to 1 oz.).
- Permanganate of Zinc (6 grs. to 8 ozs.).

Hill used the following injection, combining a number of the above together — 35 grs. each Sulphate of Zinc and Alum, 20 grs. Sulphate of Iron, 2 grs. Sulphate of Copper in 8 oz. water, in the late stage of gonorrhoea or in gleet.

Blisters or counter-irritation to the perineum may be useful in some cases.

GLOSSITIS.

If the affection arises from mercurial salivation or from iodism, the cause must be seen to, and the administration of the drugs stopped. Should there be great swelling, threatening suffocation, free linear incisions must be made. This course was necessary in a severe case under the writer's observation following the bite of a rat. The incisions in this case had to be deep, but this is rarely necessary. They should be made on each side of the middle line from behind forwards. Leeches or minute punctures may be employed where the organ protrudes from the mouth. Hot fomentations by solutions of Carbolic Acid (1 drachm in 12 ozs. of water), Chlorate of Potash (3 drachms to 1 pint), Borax or Boracic Acid (4 drachms to 1 pint), or Alum (2 drachms to 1 pint), afford relief.

Poultices to the throat and the inhalation of moist warm air should be tried.

Saline purgatives or Croton Oil may be used to cause speedy evacuation of the bowels.

As soon as the local symptoms show any formation of pus, a bold, free incision should be made deeply into the abscess by a narrow-bladed knife, and a warm lotion of Permanganate of Potash (5 grs. to 20 ozs.) should be freely used.

Syphilitic glossitis yields to small doses of Mercury (Bismodide), and excellent results are obtainable by Heath's method of picking.

the tongue in Mercurial Solution. He uses $\frac{1}{2}$ gr. of the Bichloride dissolved in 1 oz. water, and makes the patient hold this in his mouth for ten minutes by the watch, three times a day, breathing through his nose all the time. He affirms that the result is often astonishing.

GLYCOSURIA—See Diabetes.

GOITRE.

The constitutional treatment of goitre will embrace the removal of the patient from the district in which the disease is indigenous to a healthy locality with a pure water supply.

Iodine, Iodide of Potassium (5-10 grs. three times daily), Hydrofluoric Acid (10 minims of a $\frac{1}{2}$ per cent. solution), are the drugs most relied upon. They are occasionally of some use in the soft fibroid or parenchymatous forms, but prove useless in the treatment of the cystic varieties. It is very doubtful if the hydrofluoric acid is of much service. Sometimes the iodine treatment, combined with change of residence and supplemented by local applications of iodine or blistering, will effect a permanent cure.

It has been proved by Zakzewski that the continued administration of large doses of Phosphate of Sodium leads to atrophy of goitres, and the drug should always have a fair trial.

In anæmic cases large doses of Iron give excellent results.

Local treatment may be tried in many forms, the most innocent of which is the daily application of a mixture of equal parts of the Liniment and Tincture of Iodine. If a decided counter-irritant action is desired, the undiluted liniment may be painted on, layer after layer, till vesication is produced.

Iodine ointment may be used instead of the liquid preparation. Some surgeons have found better results from the application of a weak solution, applied with the view of effecting absorption of the iodine. In this case half tincture and half glycerin or weak spirit may be employed, the object being not to injure or destroy the cuticle. Ointments of Iodides of Ammonium, Cadmium, and Lead have been used (1 dr. to 1 oz.); they possess no special advantages over the pure iodine.

Bimodide of Mercury has removed goitres by the thousand in India. It has been of little use in this country. The Indian practice is to rub in for ten minutes an ointment consisting of 3 drachms of the bimodide to 1 lb. lard. The patient is afterwards to sit with his goitre exposed to the direct rays of the sun till he is unable to bear the smarting. After this some more ointment is gently applied, the patient is sent home, and the case seldom requires further treatment.

This method of dealing with goitres might be worth trial during the early days of July, when our sun is at his best, or Finsen's

phototherapy may prove to be valuable when combined with the Iodide of Mercury treatment.

Blistering with vesicating collodion or liquor epispasticus, combined with internal iodine treatment, has given moderate success in soft parenchymatous goitres, and may be tried before more formidable remedies are decided upon.

Setons passed through the substance of the gland gave excellent results in the hands of Mr. Hey, but the following treatment is less dangerous and more efficacious for the soft solid goitre.

Injection of Iodine into the tumour is a powerful means of reducing the enlargements of soft or moderately firm goitres. It is generally useless in the purely cystic variety of the disease, but may give good results in fibro-cystic forms where there is much parenchyma present. The writer has seen many successes from this treatment in the practice of the late Sir M. Mackenzie at the Throat Hospital. He has tried it himself in cystic goitre without obtaining the least benefit. Two grains of iodine dissolved in 25 minims of pure alcohol are injected by a hypodermic syringe into the substance of the gland twice a week. Some surgeons prefer to inject 30 to 60 minims of the B.P. Tincture. The greatest care is necessary to avoid puncture of a large vein or of the trachea or arteries, and the admission of air must be guarded against.

It is a good plan to compress the superficial veins by tying a piece of tape firmly round the base of the neck, below the tumour, before inserting the needle. The injection should be made very slowly by screwing home the piston, and the needle should never be inserted into the same spot in repeating the injections. As a rule, decided improvement should be visible in 6 or 8 weeks, even in large goitres, though the treatment may be necessary for several months. Generally pain and some tenderness follow soon after injecting, but they speedily disappear.

Osmic Acid, Iodide of Potassium, Ergotin, Fowler's Solution, and Absolute Alcohol have been used, but without any results warranting their selection when iodine is available. Garre has published the results of 150 cases treated by injections of Iodoform with "surprisingly favourable" results. His fluid consists of 1 part iodoform dissolved in 7 of ether and 7 of olive oil. It must be freshly prepared, and kept from the light. In the most suitable cases, the diffuse nodular and the simple hyperplastic stroma forms, 7 injections suffice.

[The injection of Iodine has two serious drawbacks—(1) It is distinctly dangerous, and sudden death has followed its use; (2), its action greatly increases the difficulty of subsequent removal should such become necessary. For these reasons modern surgeons rarely employ this treatment.—A. B. M.]

Electrolysis has been tried in 14 cases by Duncan with the result of six being completely cured. Further experience may prove the great value of this method of treating goitre. *Continued*

application of cold by means of Leiter's tubes has also given some good results.

When above treatment fails, and the growth threatens to produce suffocation, operative measures of a more serious nature may be imperatively demanded. Tracheotomy rarely will be of any benefit, owing to the nature of the obstruction. Tying of the superior thyroid arteries, with the view of starving the growth, is hardly justified by results.

Jones' operation promises to be valuable. It consists in exposing, isolating, and resecting the thyroid *isthmus*. After tying double ligatures on each side near its junction with the lateral lobes, the isthmus is removed and the wound well drained and allowed to heal up from the bottom.

By this operation, in the great majority of cases, all pressure is taken off the air passages, and danger to life is averted, and shrinkage of the lateral tumours to a considerable extent generally follows.

Excision or removal of the tumour is a serious operation, but it has been performed many times with complete success. Myxœdema will result unless a portion of the gland be left behind, and in young subjects cretinism may supervene if the entire gland be taken away.

Total removal of the thyroid body should never be performed, except for malignant disease, a portion should always be left behind, the removal of the greater portion of the gland, may be undertaken under the following circumstances—for the relief of

- (1) Severe pain ;
- (2) Urgent dyspnœa ;
- (3) When the tumour is steadily increasing in size in spite of medical treatment ;
- (4) For relief of deformity.

Kocher states that 90 per cent. of the cases which come for treatment to the hospital at Berne are so improved by medical treatment that operation is not necessary. He reports 1,000 operations. In the last 556 operations for simple colloid goitre there was only one death, and that was due to chloroform. He holds that anaesthesia is the chief danger, and recommends the local use of 1 per cent. Solution of Cocaine hypodermically without general anaesthesia.

When pressure of the tumour causes compression of the trachea, spasm of the glottis, or paralysis of the abductors of the glottis, operative interference must not be delayed. Fortunately such events are very rare in goitre.

Since the discovery that myxœdema results from complete removal, the excision of half of the gland is the operation most frequently performed. Resection of the isthmus, or scooping out of a portion of the tumour through an opening made by the *thermo-cautery*, may be tried before resorting to this.

Cystic Goitre should be treated by enucleation where possible ; when this is not admissible recourse may be had to Mackenzie's operation of tapping the cyst, injecting 1 to 2 drachms of a watery solution (25 per cent.) of solid Perchloride of Iron through the canula, by means of a special syringe designed to prevent the possibility of the admission of air. The canula is plugged and left *in situ* for 72 hours, after which the plug is withdrawn and the contents allowed to flow out. Should the liquid be found to contain blood or to show no symptoms of suppuration the injection is to be repeated the plug inserted, and the solution permitted to remain for 72 hours more. One injection generally is sufficient to establish suppuration, but a second or third may be necessary. After pus appears, the plug being withdrawn and the canula retained, free poulticing should be kept up for weeks. At first, to still further favour suppuration, the plug may occasionally be inserted so as to retain a quantity of pus for several hours. After this the cavity should be syringed several times a day with tepid water containing an antiseptic like Boracic Acid (10 grs. to 1 oz.).

In the subsequent management of the case care should be exercised to prevent the canula becoming obstructed. Hovell provides for this by inserting a piece of Ellis's spiral silver wire drainage tube into the canula, and fixing it there with the extremity projecting into the abscess cavity. When the cyst fails to contract, and the purulent discharge becomes thin and diminished in amount from flabby granulations, the cavity may be daily washed out and a solution of Chloride of Zinc (20 grs. to 1 oz.) be injected and allowed to escape.

This injection Hovell repeats till he obtains evidence that the granulations have assumed a healthy character.

The canula must be retained in the cyst till its cavity shrinks and if the granulations block up its extremity a shorter instrument can be inserted.

Multilocular cysts may be treated by puncture and injections made through the original opening.

In treating large cysts, it is advisable not to entirely empty their contents before injecting, as hæmorrhage from their vascular walls interferes with the action of the iron.

Iodine and other irritants have been used, but the above treatment is the best for ordinary cases. Small cysts may be dealt with by Porter's method, which consists in drawing off the fluid and inserting several inches of catgut, previously soaked in tincture of Iodine. The catgut is allowed to remain till suppuration is established, the canula having been withdrawn after its insertion.

Woakes has published some cases of cystic goitre which were cured by the introduction of Chromic Acid into the cyst after tapping. He introduces the acid upon a special form of instrument, introduced through the canula, and applies it to the walls of the cyst ; speedy obliteration of the cavity ensued in all his cases.

Free incision of the cyst with suturing of its margins to the skin wound, and plugging of the cavity with cotton wool, soaked in antiseptic or astringent solutions, has given excellent results in some cases.

For the results of thyroid feeding in cretinism, see under Cretinism, page 179.

GOITRE, EXOPHTHALMIC.

The treatment of this affection is anything but satisfactory. Innumerable remedies have been reported as "curing" the disease. These remedies in other hands have for the most part been found either to produce no good or to aggravate the evil. The symptoms are liable to disappear spontaneously or to subside in part for variable periods; this renders judgment upon the value of remedies a matter of extreme difficulty.

Thus Iodine has been praised and condemned. Iron has shared the same fate, but it would appear that improvement has been frequently seen to follow the alternate use of mild preparations of Iron and the administration of Quinine, for periods of about one month each.

Belladonna, Arsenic, Chloride of Barium, Ergotin, and Digitalis have each some quassi successes recorded in its favour. Veratrum Viride has also given temporary relief. Chibret and Babinski have reported most satisfactory results after the administration of Salicylate of Soda, and Phosphate of Sodium has been administered with success. Some authorities believing that the disease is caused by the absorption of an intestinal ptomaine, recommend intestinal antiseptics, and Bile from the pig has been highly recommended in large doses by the mouth, and success is reported from lavage of the colon.

Several cases have been reported as cured by the steady administration of 10 to 15 minim doses of Strophanthus Tincture four times a day, and Sparteine ($\frac{1}{2}$ gr. every four hours) has also had an encouraging report. Both these remedies possess the power of markedly diminishing the rapid pulse rate, which is a prominent feature in the disease.

Galvanism of the cervical sympathetic and pneumo-gastric has given excellent results, but no very decided opinion can be formed of the permanency of these results in the absence of carefully recorded and closely watched cases. Wolfenden has noticed the curious fact that the electrical resistance of the body is diminished almost to nothing in this disease, a current of a couple of volts passing readily through the body, and deflecting the galvanometer needle.

In applying galvanism to the sympathetic for the relief of exophthalmic goitre, a weak continuous current (not exceeding 10 or 12 Leclanché cells) may be used (commencing with half this number). The negative electrode should be placed upon the lower cervical spines, and the positive moved about upon the skin in front

of the sterno-mastoid muscles upon each side. The current from 4 to 6 cells may be applied to the closed eyelids when there is much exophthalmos.

The writer can report excellent results from the passage of the weak continuous current in this manner in one severe case, which has remained perfectly well for 8 years. His late experiences lead him to believe that the best routine treatment will be found to be Strophanthus internally, and the continuous current three times a week to the brain and neck. In applying the current to the brain, he places a pad of lint saturated with warm salt solution over the closed eyelid. Upon the top of this is placed the ordinary convex electrode.

Sansom employs the continuous current from 20 to 40 Léclanché elements, placing one pole behind the lower jaw, and the other at the corresponding point on the opposite side, or at the nape of the neck, or just above the sternum. Charcot used both Faradization and galvanism, sending the current from the former through both carotid regions alternately. The continuous current he sent from the nape of the neck through the præcordium, at the third left intercostal space. Each sitting lasted 10 to 15 minutes, every other day for six months, when a permanent cure often resulted.

Thyroid feeding has been advocated and some successes claimed; in one severe case the writer tried this plan and the patient got alarmingly worse though the dose was small. He has witnessed one death which he was satisfied was caused by thyroid extract in moderate doses. The plan of applying cold by means of Lister's tubes or ice and of utilizing the pressure of a Martin's bandage has given very doubtful results. Thymus feeding and Suprarenal extract have also been employed, but without marked benefit in most cases.

The diet, exercise, free ventilation, periods of rest and sleep must be carefully investigated and errors corrected, and everything calculated to improve the general health and tranquilise the mind should be resorted to. The importance of a change of air to the sea or a mountainous region is universally recognised.

Much attention has been of late years bestowed upon the operative treatment of this disease, and still very conflicting opinions prevail. Several cases have been cured by removal of a portion of the thyroid gland, whilst in many others it has failed, and not a few have died. The cases which are likely to be benefitted by this operation are those where there is some enlargement of the gland. Ligature of the thyroid arteries has not justified the hopes entertained of it.

The operation which seems to hold out the best prospects of a permanent cure with the least danger is the excision of the cervical ganglia of the sympathetic on both sides as recommended by Jaboulay. Pitres extols the injection of a Pravaz syringe of

(16 mins) of a solution of Iodoform in Ether into the tissue of the gland once a week and reports complete cure.

GONORRHOEA.

Nearly every surgeon of experience has his own method of treating this disorder. Nevertheless, there are certain broad lines, to travel beyond which is dangerous. Can anything be done to prevent, cut short, or modify the attack in a patient presenting himself to the surgeon during the period of incubation, before any symptoms of the disease show themselves? Astringent injections used at this period are useless, and aggravate the symptoms, which are certain to come on with greater intensity after their use, if the gonorrhœa germs have found their way into the urethra.

The best course to pursue in such a case, if the patient finds he has exposed himself to the infection of gonorrhœa is to begin washing out the urethra with a very weak warm injection of some unirritating germicide. By far the safest of these is Permanganate of Potassium, 1 grain in 5 oz. of water, made tepid before injection. In those cases where this method of treatment fails, the disease when it appears is very mild. The injections to be of use must be thorough and frequent, and when any sign of discharge appears, the quantity of Permanganate is to be doubled.

The *Abortive* treatment of gonorrhœa, after the appearance of the specific discharge is now a recognised therapeutic method, but to be successful the treatment must be commenced within a few hours after the first appearance of the pus. The method is a painful one since it is useless to attempt the destruction of the gonococci by mild astringent injections. A solution of $\frac{1}{2}$ to 1 gr. to 1 oz. of Permanganate of Potassium must be used to irrigate freely the anterior urethra every few hours by means of a fountain irrigator for three or four times. This cannot be carried out by the patient himself, but sometimes a compromise may be made by directing him to inject into the anterior urethra with the ordinary two-drachm syringe a solution of Nitrate of Silver, 15 grs. to 1 oz., or Perchloride of Mercury, $\frac{1}{2}$ gr. to 1 oz. By these heroic means the parasite may be entirely destroyed before it has had time to penetrate the epithelial lining of the urethra or invade the posterior portion of the canal.

Given an ordinary acute case of gonorrhœa, presenting itself to the surgeon a few days after the appearance of the discharge, the best routine will be a judicious selection of internal and local remedies. He should take as much rest in the recumbent posture as is practicable, and should feed upon a mild light diet of milk and weak soups, avoiding alcohol in every form strong tea and coffee, and all indigestible dishes. If smoking in moderation acts as a solace to him this need not be prohibited. A suspensory bandage is necessary where the ordinary avocation must be followed. The first indication is afforded by the state of the *urine*; this should be kept alkaline and abundant, so as to

thoroughly flush the urethra. The writer's plan is to prescribe the ordinary Potash or Kali Water, in the effervescent form, *ad lib.*, taken with a little fresh lemon juice.

The common mistake at this stage is to begin with stimulating diuretics like Copaba, or Cubebs, and to use astringent injections. The only internal specific drug in the early stages which is safe is the Oil of Santal Wood, 20 mins. in capsule or emulsion ter in die. Later on the more reliable drugs may be prescribed, and of all internal remedies, new and old, Copaba stands at the head, notwithstanding its disgusting flavour. Capsules do much to mask this, but the odour of the eructations is sometimes very annoying. Emulsions are very liable to upset the stomach. Cubebs may be easily combined with it, though some prefer to give the powdered cubebs alone in milk.

The following is by far the best means of prescribing Copaba :—

R. Pulv. Cubebr. ℥ij.
Pulv. Potass. Nit. ℥ij.
Pulv. Doveri ℥ss.
Ol. Santal. ℥ij.
Bals. Copaba q.s. ut fiat

electuarius durum. Signa—"The size of a hazel nut to be taken in wafer paper, three times a day, two hours after meals."

The following mixture may be ordered :—

R. Bals. Copaba ℥vj
Liquor Potassæ ℥ij.
Mucilag. Gum. Acacie ℥j.
Spt. Etheris Nit. ℥ij.
Aque Cinnamomi ℥vss. misce

Fiat mistura. Capsul. cochlearium magnum ter in die, p.p.a., post cibos.

The rash (often mistaken for measles) which sometimes appears after the administration of Copaba, fades rapidly upon the temporary suspension of the drug. Cubebs or its oil acts almost as reliably as Copaba, and may be given alone or in combination with it. Turpentine, Eucalyptus Oil, Piper Methisticum, Pulsatilla, Buchu, Arbutin, Benzoic Acid, Hydrastis, Thallin, Salol, Hazeline, Ol. Gaultheriæ, and many other remedies have their admirers and advocates, but the above-mentioned will be found

to fulfil all requirements. Cantharides, though vaunted highly, is a dangerous remedy, even in small doses.

Scherck uses capsules each containing 10 mins. Santal Oil and 5 grs. Cystogen (ammonio-formaldehyde); this latter substance splits up in the acid urine, and the resulting formaldehyde is germicidal.

Chordee at this stage is sometimes a very severe symptom. The most reliable treatment is a large enema of warm water, after which a suppository like the following may be inserted:—

R. *Extracti Belladonnae* Vrr. gr. iv.
 Morphinae Hydrochloratis gr. iii.
 Pulveris Camphoræ gr. xl.
 Olei Theobromatis gr. lxx. misce

secundum artem et divide in partes æquales viij. unam utendum ut dictu hora somni vel dolore urgente.

Bromide of Potassium (30 grs.), with 5 grs. Camphor and 10 grs. of Chloral, may be given when Opium and Morphia are contra-indicated. Cannabis Indica Henbane, Lupulin, Antipyrine, Phenacetin, Monobromate of Camphor, Atropine, Tobacco Enemata, Aconite, and many other remedies are recommended; but Camphor and Opium meet all requirements. A Nitrite of Amyl capsule may be used for inhalation, or in very severe cases a 2 per cent. Cocaine Solution may be injected.

The local treatment of the disease is more important than the constitutional, and one of the most vital points in the therapeutics of gonorrhœa is the selection of the time at which this should be commenced. The French plan of waiting till internal treatment has caused the acute symptoms to subside and the discharge to diminish before beginning injections has much in its favour; the old plan of using strong astringent Zinc, Silver, and Copper solutions in the acute stage often did much harm. In the opinion of the writer, the introduction of the comparatively un irritating Permanganate in the treatment of gonorrhœa has rendered the French plan obsolete. From the earliest stage a weak Permanganate of Potassium solution (1 gr. in 5 oz.) may be injected warm, every few hours, without any danger. The strength can be gradually increased till 1 gr. to 1 oz. is reached. In the great bulk of mild cases taken early no further local treatment is ever required. Where the disease has extended to the posterior urethra this remedy will often suffice, though it may have to be injected by the irrigator.

Dr James Moore finds that the best results are obtained by the use of the Permanganate of Zinc. He injects $\frac{1}{4}$ gr. per oz. at first, and gradually increases the strength till $\frac{1}{2}$ gr. or more per oz. is tolerated. It is much more decidedly astringent than the

Potassium Salt, and may probably supersede it, though the writer has always used the older remedy. His plan is, as already stated, to begin with a weak solution containing 1 grain in each ounce of distilled water, with directions that at first it is to be diluted with an equal volume of warm water before injecting. The quantity of water is to be diminished each day till the full strength of the injection is used. All urethral injections should be used tepid or warm, and it will suffice for all ordinary purposes if the patient keep a small bottle of the fluid in his trousers pocket, where it soon becomes of the same temperature as the body.

The urethra should be first well washed out with a stream of warm water after micturating, when 2 or 3 drachms of the solution should be injected slowly down the urethra, and its return prevented by grasping the head of the penis firmly between the fingers for two or three minutes. The frequency of the injections will depend upon the nature and strength of the solution and the peculiarities of the case. As a rule, it is much better to *inject a weak solution frequently than a stronger one less often*. It is one of the many virtues of the Permanganate solution that there is little danger in overdoing it in this direction. Little or no smarting should follow its use after a few trials, and, if smarting result, the injection should be diluted.

The writer believes that the successful treatment of gonorrhœa by injections depends, upon the whole, much less upon the nature of the injection than upon skill in prescribing it. He would, therefore, venture to suggest to the young practitioner the advisability of selecting one drug and adhering to it persistently, varying its strength and altering the frequency of the injections according to the effect desired or produced. By these means he soon becomes master of the remedy, and he will be astonished to find how much he will be able to do with it, and how easily he can alter its effects to suit the constantly-changing conditions of the diseased state. The endless varieties of injections tempt the physician to change from one to the other, to the detriment of the patient and to the deterioration of his own experience. This principle applies to every department of treatment, and is one of the secrets of the success of some physicians, whose conservative prejudices have prevented them from trying most of the new and worthless drugs daily written up in the current literature of medicine. The man who is patron of all *drugs* will too often be found not to be master of a single *remedy*.

Bichloride of Mercury is an excellent local remedy in gonorrhœa, and, possibly, it is the best of all. The writer has had little experience of it in this disease however, because since he has adopted the practice of using the Permanganate, he has scarcely ever found it fail to do all that could be desired of it. The strength of the solution may be varied to suit the stage and severity of the affection. As a rule, an injection containing $\frac{1}{4}$ gr. in 16 ounces of water is a safe solution to begin with. This is

1 in 14,000, and may be injected warm every hour or two hours. In three or four days the strength may be gradually increased till twice this proportion of the bichloride is employed.

The physician can order 1 grain to be dissolved in 16 oz. of water, with directions that this is to be diluted, at first, with an equal quantity of *hot* water, the water to be gradually diminished till the full strength is employed. The salt should not be increased above 2 grs. in the above quantity of water (*i.e.*, 1 in 3,500). It is speedy, safe, and certain in its action, and has been found equally efficacious in the specific and in the non-contagious forms of urethritis.

Salicylate of Mercury, 1 grain in 4 or 5 oz. of water, has been greatly extolled.

Sulphate of Zinc is by far the most frequently-employed injection in gonorrhoea. It is used in strengths varying from 1 to 3 grs. in each oz. of water. The latter proportion is too great for safety, as it is liable to produce pain and aggravation of the symptoms, as well as to induce epididymitis. Any strong solution may bring about this latter complication.

Acetate of Zinc (2 or 3 grs. to 1 oz.).

Chloride of Zinc ($\frac{1}{2}$ to 1 gr. in 1 oz.).

Sulphocarbolate of Zinc (2 grs. to 1 oz.).

Carbolic Acid (6 grs. to 1 oz.).

Mercuriol (1 gr. to 1 oz.).

Dermatol Emulsion (30 grs. to 1 oz.).

Chloral (2 grs. to 1 oz.).

Boracic Acid (10 grs. to 1 oz.).

Nitrate of Silver ($\frac{1}{2}$ gr. to 1 oz.).

Acetate of Lead (3 grs. to 1 oz.).

Tannin (5 grs. to 1 oz.).

Alum (3 grs. to 1 oz.).

Creolin (6 per cent.).

Iodoform (10 grs. to 1 oz.).

Perochloride of Iron (1 minim of the strong liquor to 1 oz.).

Decoction of Lemons.

Citric and Salicylic Acids (2 grs. and $\frac{1}{2}$ gr. to 1 oz.).

Ricord's Injection of Sulphate of Zinc and Acetate of Lead (5 grs. each to 1 oz.).

Ichthyol (1 per cent.).

Berkley Hills Injection. (See under Gleet.)

Guiteras uses a modification of Uitzmann's injection—10 grs. each Sulphate of Zinc, Alum, and Carbolic Acid, 1 oz. Glycerin, and water to 8 oz.

Silver Salts.—Great attention has been paid to the action of the Salts of Silver in gonorrhoea, and already the literature of these has become extensive. The organic salts have been greatly extolled on account of their germicidal properties, whilst at the same time their power of coagulating cell protoplasm is much less than that of the inorganic salts. The following list represents the

most reliable of these agents—Protargol, Largin, Argentamine, Argentol, Actol, Itrol, Ichthargan, Argonin, Collargol, all of which are regarded by some authority or another as specifics for gonorrhœa. Protargol, which contains about 8 per cent. of silver, is the best silver salt for acute gonorrhœa. A $\frac{1}{2}$ per cent. solution is injected three times a day, and retained for ten minutes if the posterior urethra is involved. Where the anterior urethra only is affected two or three consecutive injections retained for three minutes each suffice. Largin may be used in the same way. The injections should be increased to 1 per cent. Protargol is quite painless, but Largin causes considerable smarting, and is more penetrating. After the acute stages, Zinc Salts may be used in conjunction with these.

The ideal treatment appears to be in the use of a 1 to 2 per cent. Protargol injection, after copious irrigation with Permanganate of Potassium or weak Sublimate solutions.

The Nitrate was formerly much used, but it is painful, and since the introduction of the organic salts it is now seldom employed, about 1 gr. in 5 oz. water is a good working strength.

As mentioned under Gleet, bougies called Antrophores, consisting of a solid soluble gelatin basis, containing 2 to 5 per cent. of Thallin, the whole enclosed in a fine nickel-plated spiral, are employed in the treatment of gonorrhœa. They are inserted into the urethra and left *in situ*. Solid bougies made up of a similar basis and containing Iodoform and Eucalyptus, are employed in the same way, and nearly every drug mentioned above has been used in this form. Protargol is used in this way by many French and German surgeons.

Irrigation.—Any description of the treatment of gonorrhœa would be incomplete without a reference to the method employed by Janet and others especially as this, when carried out by the surgeon himself is the most efficacious and speedy of all treatments, but it cannot be entrusted to the ordinary patient. A nozzle fitting the urethral orifice has two arms; that of Chetwood being the best; this is shaped like the letter Y. One of the arms is attached to the rubber tube of a cistern containing the injection. Upon raising this to the height of about four or five feet, with the leg of the nozzle in the urethra, the fluid distends the entire anterior portion of the urethral canal, and may be permitted to flow out through the other arm by utilizing a shut-off contrivance. One daily irrigation with about 40 oz. of a solution of 1 gr. of the Permanganate of Potassium in 6 oz. water, gradually increased to 1 gr. in 3 oz., suffices to destroy the gonococcus in about ten days. After three or four days the cistern is raised at each sitting to about eight feet, and this overcomes the resistance of the cut-off muscle and permits of the posterior urethra being thoroughly flushed out. It is, however, safer to irrigate the posterior urethra by means of a soft catheter introduced to within about one inch of the bladder, and when this viscus is filled the patient is directed

to void his urine, which flushes out the entire urethral canal. Bichloride Solution may be used instead of the Permanganate.

It must not be forgotten that during the treatment of gonorrhoea by injections, especially if these be of full strength, the discharge may continue till the treatment is suspended, after which, in a few days, the patient may be found to be quite well.

Non-specific urethritis will speedily yield to any of the injections already mentioned.

For complications, see under Rheumatism, Conjunctivitis, Orchitis, Cystitis, &c.

Gonorrhoea in women is to be treated upon the same lines, and the disease rapidly yields to Permanganate Solution, 10 grs. to the pint. The only point worth remembering in these cases is that the vagina should be well washed out with at least a quart or three pints of warm water before injecting. As the discharge lessens Sulphate of Zinc (1 drachm to the pint) may be used, but upon the whole the best routine treatment will be found in a mixture of equal parts of powdered Alum and Borax, of which a table-spoonful may be dissolved in three pints of warm water, and injected when nearly cold three or four times a day, after washing the passage out with warm water. Some authorities insist upon the great danger of spreading the infection to the upper genital tract by treatment and condemn all local applications, relying entirely upon absolute rest in bed and the administration of diuretics as Ichthylol, Copaiba, Boric Acid, Sandal Wood Oil &c.

When pyosalpinx occurs as a rule operative measures are called for. Removal of the tubes, with or without the ovaries and uterus, is practised. As a rule free incision of the posterior vaginal fornix and the thorough evacuation of all pus from the pouch of Douglas, and Iodoform gauze dressings, meet most of the indications. (See under Pyosalpinx.)

The treatment of the grave complications which sometimes follow gonorrhoea in the female is mentioned under Endometritis and Pyosalpinx.

When cystitis supervenes, the remedies mentioned upon page 77 are to be resorted to. Medicated pessaries, containing Iodoform, Carbolic Acid Creolin Resorcin, Ichthylol, and other antiseptics are both convenient and efficacious.

GOUT.

The treatment will embrace the management of the case (1) during acute attacks, (2) between the attacks, (3) during the chronic stage. The diet in acute or transient gout should be chiefly liquid, no solid animal food being permitted. After the first day, farinaceous puddings, eggs, weak beef-tea, and chicken soup may be given. Concentrated beef essences and strong soups are only allowable when the attack is occurring in a broken down constitution.

Two systems of managing gout have been tried, one consisting of administering large draughts of hot or warm water, alternating with quantities of weak soup, the other is known as the "dry cure," and consists in the administration of dry food, like hard biscuits, without any liquids at all. Neither exclusive method of treating acute gout has been followed by results justifying further trial. Where the attack is occurring in a middle-aged strong subject the aim should be to feed him upon as low a diet as possible consistent with safety, milk, barley water, weak arrow-root, toast and water being given freely. In those of weak constitutions, the aged, and those who have suffered from previous attacks, this treatment must be modified considerably, a fairly generous allowance of food being given with as little nitrogenised element as possible.

Stimulants must, unless in very exceptional cases, be forbidden. In the presence of debility or intemperate habits, alcohol, in limited amount, is called for, and then wines of all kinds are contra-indicated. A moderate quantity of good old whiskey is by far the most suitable stimulant in these exceptional cases. Next in value to it will come good brandy and pure gin, and the stimulant should be combined with the food, whiskey or brandy and milk making an acceptable beverage, whilst gin may be given after food with an effervescing liquid.

As the attack passes off the diet may be improved, fish, fowl, oysters, and vegetables being permitted.

Medicinal treatment at this stage will consist of one smart saline purge and the administration of Colchicum. About the value of this drug in gout much has been written, and many strongly insist upon its numerous bad qualities, and affirm that it should never be given, as it causes the disease to return and show itself in worse forms, and that its administration is liable to cause mischief to fly from a safe region to a vital organ, &c. Garrod, Yeo, Roberts, Bartholow, and, indeed, most of the best modern authorities, recommend the remedy almost as a specific, and there cannot be any danger in using it in moderate doses under strict and close surveillance. Differences of opinion regarding the value of colchicum in gout appear to spring from attempts at understanding its pharmacological action. Those who are satisfied that the drug is a very poor and unreliable diuretic soon persuade themselves that it cannot be of much service in gout. Whatever be the explanation of its undoubted value, it is clear that it does not depend upon its diuretic action.

There are several methods of administering colchicum in acute gout. All authorities agree on one point—viz., that purging by the drug is not necessary, and that vomiting caused by it is highly objectionable. It is never advisable to produce the physiological effects of the drug in treating this disease. Called to a patient in an attack of gout, 40 minims of the wine may be given at once, and 15 minims every 4 or 6 hours afterwards. It will be safer to

give 15 minims at first, and 10 minims every hour or two for 6 or 8 doses, till pain is relieved in very smart attacks. The drug may be given with advantage in combination with alkalis, or in effervescent mixtures containing bicarbonate of potash, which can be given with lemon juice, or as the white mixture.

R. *Vini Colchici* ℥iv.
Magnesi Sulph. ℥iiss.
Magnesi Carb. Pond. ℥ii.
Aque Menth. Pip. ad ℥xii. *misce.*

Fiat mistura, cujus capiat ℥j. quartis horis p. p. a.

Where there is much prostration, saline purges and the above mixture are contra-indicated. In such cases a dose of Rhubarb and Colocynth pill, or $\frac{1}{2}$ gr. Podophyllin, may be given with advantage.

Opium, Chloral, and Morphia are used for the relief of acute pain. If possible, it is far better to avoid these remedies and trust to local treatment, but where the agony is intense the hypodermic injection of Morphia must be resorted to. Hyoscyamus, Belladonna or Atropine will generally prove of little value, but, as pointed out by Tirard, Hyoscyne or Hyoscyamine may be safely given, and they will be also valuable where insomnia results from the attack. Large doses of Bromides may be used at the same time.

Where diuretic and diaphoretic action is required—viz, where there is a scanty quantity of urine and a hot, dry skin—the colchicum may be replaced by 3 grs. of Citrate of Lithia in 5 oz. of Potash water and a little Lemon Juice every hour for 4 doses, then every 2 or 3 hours, or large doses of Citrate of Potash may be given. Elimination of uric acid by this means is speedy and beneficial.

Sabicylate of Soda has of late years been much used in the treatment of gout, instead of colchicum, to assist the elimination of the excess of uric acid in the blood, it diminishes fever and relieves pain. It may be given in doses of 30 grains at the beginning of the attack, and repeated every four hours in half this amount. The writer has seen most satisfactory results from its administration in acute gout, but many authorities, including Luff, deny its value, and even affirm that it is contra-indicated. There cannot, however, be the same objection to the Potash Salt, and Sabicylate of Potassium is the drug extolled by Edmund, who also strongly recommends Potassium Bitartrate as a beverage—20 grs. drunk several times a day dissolved in half a pint of hot water.

The local treatment of acute gout resolves itself for the most part into the use of remedies for the relief of pain. In those cases where the pain is "bearable," the best course to follow is to place

the affected joint in a position of absolute rest surround it with thick layers of warm and dry absorbent wool, covered in by a piece of thin mackintosh, the whole being evenly and lightly bandaged, and placed upon a pillow in a slightly elevated position. The wool should be changed every 24 or 48 hours, and a fresh dry warm supply applied.

Leeching invariably does some mischief. Poulticing is also objectionable, and cold lotions or compresses may cost the patient his life, and arnica *never* should be employed. The application of a strong solution of Nitrate of Silver appears to act beneficially only by substituting one form of misery for another. A very hot foot-bath or warm fomentation of Poppy capsules and Chamomile Flowers gives some relief. A piece of flannel wrung out of hot water and sprinkled over with liniment of Belladonna or Aconite may be tried. These liniments or Chloroform liniment may be applied upon lint and covered over with oiled silk, or the joint may be smeared over with the Extract of Belladonna rubbed into a cream with Glycerin Veratrine or Aconitine Ointments, Oil of Peppermint, Tobacco Leaves, Lotions containing Cocaine Chloral, Iodide of Potassium, Iodine, Saheylates, Lithia Salts, Cajuput Oil, Iodoform, Alkaline Solutions, Solution of Morphine and Atropine (2 grs. and 1 gr. to each drachm) Spirit Lotion, and Ether and Water, have been used with various intentions and varying successes. Yeo strongly recommends a lotion of 4 drs. Carbonate of Soda, 2 drs. Laudanum in 10 ozs. water, this mixed with an equal amount of *hot* water is applied to the joint on lint, under a liberal covering of wool, and the whole surrounded with oiled silk.

Blisters have been used with doubtful results. Their beneficial effects are best seen in some cases of chronic or irregular gout.

Where the attack is interrupted by the appearance of symptoms characteristic of *suppressed, retrocedent, or irregular* gout, the principles embodied in the previous remarks are to be carried out. The first point to attend to in such cases is to induce a rapid and immediate elimination of the poisonous material in the blood by the kidneys, skin, bowels, or certain joints or tissues. Colchicum must be used in such cases with unusual circumspection, purely eliminatory treatment being more reliable. Symptoms of collapse following the invasion of the vital parts, as the heart, nervous system, or stomach, must be met by general stimulants and free counter-irritation of joints which have been known as the former local indicators of gout. This can be done by very hot fomentations with Mustard and Water, Turpentine stupes, Cayenne, liquid blisters, or local or general *hot* packs.

The treatment of the disease during the intervals between the attacks, or in the period succeeding a first attack of gout, should be directed to the prevention of further attacks or the prolongation of the intervals, and the removal of local remnants of former joint troubles.

With these objects in view, every surrounding and habit of the patient's living must be inquired into and scrutinized, and the most rigid rules laid down for his guidance, especially should he be the victim of a strong hereditary tendency.

Everything that can possibly increase the abnormal formation of uric acid is to be forbidden or corrected, and every measure which in any degree increases, stimulates, or assists in the elimination of this product after its formation is to be encouraged.

Diet, next to heredity, is the most potent factor in producing gout. Conflicting opinions prevail upon the advisability of eliminating certain articles of food, but all authorities are at one in condemning general gourmandising or excesses in eating. The very large surplus which the majority of mankind pushes down the throat over and above what is really necessary to maintain life is not to be cut completely off, but the victim of gouty tendencies is certainly called upon to very materially diminish this surplus. Obesity is what he should dread, though he may partake of fat and butter freely.

Animal food in ordinary amount is condemned by most writers, and Roberts' advice should be followed—*i.e.*, to advise the gouty patient to partake cautiously of butcher's meat, fowl, game, and cheese, and to partake as freely as his digestion will permit of bread, rice, garden vegetables, salads, and fruit; he states that a diminution of one or two grains per day in the amount of urates thrown into the circulation may make all the difference between the occurrence or non-occurrence of an arthritic attack.

The accessory dishes are the source of danger to the gouty. Pastry, sugar, puddings, entrees, pork, game, sweets, and sweet fruits are to be avoided. According to Draper, on the other hand, the cardinal feature in the gouty diathesis is the feeble capacity for the digestion and assimilation of carbohydrates and their derivatives, and this affords the guiding principle, in his opinion, for the regulation of the gouty dietary.

Some physicians, looking to the dangers of the formation of uric acid from a purely nitrogenous or meat diet, exclude it entirely, and the patient turns to a food chiefly made up of starches. Both extremes are very objectionable, and of the two probably the starchy diet is the more objectionable, though the writer has witnessed serious results from the Salisbury diet of beef-steaks and hot water. Milk, butter, cream, fats, and vegetables in fair amount, and celery and salads, may be freely permitted. Potatoes are objectionable. Water should be very freely used as a beverage. Two or three tumblerfuls of warm water daily are of the greatest value in nearly every case, and the writer advises gouty patients to add a little good cream which completely does away with its mawkish taste.

Roberts lays great stress upon the bad effects of Chloride of Sodium, and strongly advises Chloride of Potassium to be freely *used instead of common salt*.

About wines, beer, and all fermented liquors, there can scarcely be a doubt that all are objectionable, and should be strictly avoided. It will, however, be found that this rigid rule will be resented by most patients, and it becomes the painful duty of the physician to express an opinion about the *least* objectionable member or members of the group. This is no easy matter. Although all authorities condemn the entire group, nearly every one of them is permitted as the least objectionable tipple by *some* authority.

Thus good old Port is even advocated by some physicians. Roberts says that "the most suitable are good Claret, Hock, Moselle, Chablis, or Sauterne, and good dry Sherry suits some gouty patients well." The writer has seen this latter wine, "good and dry," become the sole cause of bad gout in a patient who never took any other form of stimulant. It is almost better to insist upon all and each of these being decidedly injurious, and leave the responsibility of nominating his own poison to rest upon the unfortunate victim. Poor human nature soon twists the doctor's opinion of "least objectionable" into a decided "permit," and excess is the common result.

Where an alcoholic stimulant is deemed necessary, there can be no doubt about the best. Whiskey, Brandy, or Gin, *well diluted* with an alkaline effervescing water, and always given along with or immediately after food, is, from the gouty point of view, almost free from objections.

In gouty patients sometimes one excess in the use of fermented liquors will bring on an attack and in some an attack may follow one excess in eating. The lesson to be enforced, therefore, is temperance in all things. Some authorities insist upon the fact that it is the quality and not the quantity which is injurious. There is no doubt that inferior wines are poisonous to the gouty patient, who can *sometimes* indulge in really good wine without suffering from it.

Exercise comes next in importance to diet as a factor in the treatment of gout, though if the writer judged entirely from his own limited experience in gout, he would say that he has observed much more mischief to follow want of muscular exercise than to supervene upon errors in diet. Free open-air exercise (the best form being smart walking) should always be insisted upon. It should be pushed to the extent of fatigue and one long walk, ending in moderate "tiredness" and a fair amount of perspiration, is a duly remedy of great efficacy in the treatment and prevention of gout. Mere moving about in the open air, as most members of the upper classes do, will not suffice, and the class of patients generally afflicted with gout do not relish smart walking. If the patient be not too old, he should be advised to try an outdoor game, like golf.

Horse exercise is very beneficial, and may be freely indulged in by those whose physical condition permits of it.

Indolent habits are to be given up, early to bed and early to

rise being the motto. Many instances are to be met with where confirmed gout in middle-aged subjects, which had resisted all treatments, has disappeared upon some reverse of fortune which necessitated the abandonment of all luxurious habits and compelled the victim to lead an active and useful life. Freedom from worry or excessive brain strain is desirable; but honest, hard work, mental or physical, is a good antidote. It is, of course, impossible to carry out these principles in chronic invalids suffering from gouty joints and other locomotive disabilities. For them Massage is a boon if persistently employed.

Sea or Cold Bathing for the vigorous, or Wet Packs daily for the crippled are highly beneficial. The Turkish Bath is to be recommended with caution. Change of air is beneficial if carried out with judgment, a dry warm or temperate atmosphere suiting most cases in the winter, the sea being avoided especially where there is a tendency to skin troubles. Many resorts are sought out by gouty patients where a course of alkaline mineral waters can be had; of these the best is Carlsbad (Sauerling spring). The great value of drinking the warm alkaline water has been long recognised in its property of preventing attacks and of removing renal, hepatic, and nervous disorders resulting from gout. In the opinion of most competent authorities the alkaline mineral waters exert their beneficial effects through their action upon the liver and alimentary canal. The Carlsbad gout cure embraces more than merely sipping the water; exercises, bathing, diet, and other matters are carefully attended to. Roberts advises patients to avoid all resorts where the waters are charged with soda salts, and recommends at home, Bath, Buxton, and Strathpeffer, and the baths with the internal use of the waters, may be tried for some months. The best springs abroad are Carlsbad, as already mentioned, Aix-les-Bains, Contrexéville, Gastein, Pfaffers, Wilbad, Vittel, and Bâges, though Kissingen, Vichy, and Homburg are also much prized.

The waters imported from many mineral springs are in constant use, and the best of them are Friedrichshall, Hunyadi Janos, Carlsbad, and Vichy. Contrexéville water, to be of use must be taken as it is at the spring in very large doses. About one gallon per day is not a very high average amount for the gouty or calculous patient to consume.

The medicinal remedies available in the treatment of gout, either with a view of preventing attacks or of removing local manifestations of the disease, will embrace the use of remedies whose action will be chiefly exerted upon the eliminatory organs.

Alkalies, by forming soluble salts with uric acid, which salts acting as diuretics, are freely washed out in the urine, cause excretion of uric acid and are the most valuable of gouty remedies. Though Roberts believes them to be worthless, they are still highly prized by others.

Potash Salts in full doses (20 grs. of the Bicarbonate four times a

day or of the Citrate) are certainly preferable to the corresponding Soda Salts.

Lithium forms soluble salts with uric acid, and is much valued as a remedy in the sub-acute attacks of gout though many authorities deny this. Carlsbad Salt and other alkaline springs act in a similar manner.

Salts of the alkaline earths act in a similar way, and the Lime and Magnesium Waters are much prized by some physicians.

Disorders of the stomach, liver, bowels, and kidneys are to be met by appropriate treatment directed to these organs.

Salicylic Acid or the Soda Salt is given with the view of assisting in the elimination of uric acid. Very divergent views are expressed upon the subject, and, as already mentioned, the Potassium Salt is better.

Though it does not appear to really cut short or cure the disease, it is of great value in relieving the urgency of many of the symptoms, especially the cardiac and pulmonary distress. The proper indication, therefore, for the exhibition of Salicylates would appear to the writer to be during the attacks of acute or chronic gout, and not in the intervals.

Benzoates, either in the form of Benzoic Acid or the Benzoates of Sodium and Lithium, have been much used as preventives or cures for gout. Beyond their diuretic action there is not much encouragement to be found in perusing the clinical reports of cases where they had been extensively tried.

Phosphate of Ammonia is recommended as a preventive of acute attacks and if given in doses of 10 to 20 grs. for long periods in solution, well diluted, it is of great benefit in chronic gout. Haug insists upon the great value of a course of pure Phosphate of Soda in the chronic forms of gout, and in the intervals. Chloride of Ammonium acts in much the same way. It is indicated in the intervals between the attacks of acute gout, especially where neurotic troubles remain as evidence of the presence of uric acid still in the system.

Piperazine has been vaunted as a specific for gout, but the testimony of most authorities is certainly against it. Lysidine and Urotropine have not fulfilled the expectations of those who first praised them.

Iodide of Potassium is of great value in chronic gout, or in the intervals between acute attacks. When there are renal or vascular complications there is no remedy to equal it, and it is also of great service in the treatment of local joint troubles in the chronic forms of the disease. The writer has given it in such cases with benefit, combined with alkalies and a small amount of Colchicum.

R. Potassii Iodidi ℥i.
Potassii Bicarbonatis ℥vi.
Vin Colchici ℥i
Aque Camphoræ ad ℥xii. m℥c.

Fiat mistura, cujus capiat ℥ss. ter in die ex ℥ii aquæ post cibos.

Free Iodine has been much praised by some practitioners, but it has not found much favour.

Guaiacum may be used with advantage in doses of 5 grs. three times a day. It is indicated in the more chronic forms of the disease where the painful condition of the joints appears to be almost constant. Garrod speaks in the highest terms of it in such cases. Where the affection closely simulates chronic rheumatism it is most useful. The Chelsea Pensioner (see Author's work on "Materia Medica and Therapeutics," 7th Edition, page 391) is a famous electuary, containing in addition to Guaiacum, Sulphur, Rhubarb, Mustard, and Nitre. It may be given in doses of one tea-spoonful morning and night.

Sternfeld, of Munich, recently has reported excellent results from Quinic Acid. He gives it in tablets in the form of Lithium Quinate, 6 eight-grain tablets being given daily, and he claims for it a specific action equal to that of the Salicylates in acute rheumatism. It is also known by the name of Urosin.

In chronic gout the disease has become so thoroughly established that when the patient is not suffering from sub-acute attacks he is groaning under constant complications of an arthritic, renal, neurotic, asthmatic, cardiac, or cutaneous nature, which may render life almost unendurable. The guiding principles for the treatment of such cases are those just discussed. Diet, exercise, baths, Alkaline waters, purgatives, Colchicum, Iodides, Alkalies, change of climate, Benzöates, Guaiacum, Arsenic, Iron, Tonics, massage, warm clothing, Salicylates, &c., are to be carefully weighed, and their proper and judicious selection decided upon by the special features of each case. Treatment directed to the local troubles, or complications, is to be based upon the general principles mentioned under the heading of the part affected. The two great points in the treatment of every stage of gout are to be emphasised here, viz., *diminished formation of uric acid, and increased elimination.* The latter consideration will suggest the closest attention to renal functions. The concretions of urate of sodium existing in the neighbourhood of joints are not to be lightly meddled with. Since they are for the most part isolated from the blood by non-vascular tissues the ordinary remedies used for their removal as alkaline lotions, weak electric currents, liniments, friction, massage, blisters, &c., are seldom of much use. Unless when interfering considerably with comfort or the action of joints, the limb may be best treated by continuous, dry warmth. Where a necessity exists for their removal the skin may be incised and the mass turned out. This is seldom necessary. Edison, of New York, has demonstrated that gouty concretions may be diminished to a remarkable extent by the application of electrical endosmosis.

For the stiffness and pains of chronic gout troubles the new Electro-thermic Generator is of much use, and A. S. Myrtle has obtained excellent results from it by a 40 minute local application of a heat of from 300° to 360° F.

Cataphoresis has been tried, and often relief is obtained, the idea that the current decomposes the Lithium solution generally used, and that the freed element enters the blood and combines with the gouty concretion is erroneous, but nevertheless the relief and increased mobility of the joints are marked.

HÆMATEMESIS.

The majority of cases will be found to be associated with gastric ulcer, and the question is dealt with in discussing the treatment of Gastric Ulcer (page 313). Absolute rest in the horizontal position, and physiological rest to the stomach, as far as possible, should be maintained. Ice, swallowed in small pieces, should be the only substance permitted to enter the stomach. In severe cases, stimulants, food, and even medicines, must be administered by the bowel.

Externally, iced compresses in thin subjects, and dry cups and smart sinapisms, where the abdominal walls are thick, may be employed in severe cases. If iced compresses are used, they should not be kept on longer than 30 minutes at a time as congestion of the gastric membrane will occur. Hot foot-baths, with or without Mustard, tend to diminish hæmorrhage by acting as revulsants.

Opium or Morphia, given as a suppository or by hypodermic injection, arrests peristaltic action in the stomach, allays nervous excitement, and calms the circulation, putting the patient into the most favourable conditions for recovery. A little Morphia ($\frac{1}{4}$ gr.) may be placed upon the tongue and washed down with a teaspoonful of iced water, but as a rule it is well to avoid administering drugs by the mouth, except in urgent cases, as their presence often aggravates by exciting increased peristalsis and vomiting.

There are really only two drugs which exert a special action in internal hæmorrhages, one of these is Chloride of Calcium, which by rapidly increasing the coagulability of the blood will help the vessel to seal itself. It may be given in 30 or 40 gr. doses by the rectum dissolved in plain water, or added to a nutrient enema. The other reliable internal hæmostatic is Suprarenal Extract in doses of 5 grains.

Gelatin (1 to 2 per cent.), when given hypodermically in solution with common salt, has been also demonstrated to possess the power of increasing the coagulability of the blood.

Where it is decided to try the old hæmostatic remedies, Ergotin may be administered, subcutaneously, in the form of the W.W.

hypodermic injection, in doses of 10 minims every 3 or 4 hours : it is of little use.

Where these measures fail, styptics may be tried by the mouth, and the following may be used. They are enumerated in the probable order of their merit.

Tannin, given dry in water paper or in solution, 10 grs. in iced water every 2 hours.

Perchloride or Pernitrate of Iron or Sulphate of Iron. The weak solution of the Perchloride, in 30 minim doses in iced water, is the least objectionable.

Acetate of Lead, in doses up to 5 grs., may be administered in solution every 2 or 3 hours in severe cases. It is useless to order it in the pilular form for hæmorrhage from the gastric membrane.

The following is a useful formula —

R. *Plumbi Acetatis* ʒj.
Acid Acetic Dil. ʒiiss.
Liquor. Morphine Acet. ʒiiss.
Aque Destillatæ ad ʒviin. *misce*

Fiat mistura, cujus capiat ʒss. secundis horis ex paululo aquæ.

Alum, in 10 gr. doses in solution every 30 minutes, sometimes proves successful. In large doses it is emetic. It may be advantageously combined with Dilute Sulphuric Acid.

Galic Acid may be tried in doses of 5 to 10 grs. and some believe it to be more efficacious than tannin ; this is not likely. It may be combined with Sulphuric Acid with advantage. Hæmatoxylin, Krameria, Kino, and the entire list of vegetable astringents containing tannin have been from time to time recommended, but they are, in the writer's opinion, practically valueless.

Nitrate of Silver in one large dose (1 grain in *fresh* pill) may be tried.

Vinum Ipecacuanhæ has been extolled in 1 or 2 minim doses. It probably would be equally efficacious if applied externally to the skin of the abdomen in the same heroic proportions.

Creosote, in the capsular form, has checked, for the writer, small hæmorrhages in a very satisfactory manner.

It is a matter of vital importance to give the remedy after the stomach has been cleared out by vomiting so that it may come into contact with the bleeding spot without dilution ; the nurse or patient should be told to repeat the dose then without delay.

Where the hæmatemesis is the result of congestion, caused by hepatic disease a large dose of Sulphate of Magnesia, or Calomel, followed up with ice and revulsive measures, will be advisable. Watson's treatment was 5 grs. Calomel at night, and 2 oz. Black Draught in the morning.

Hamamelis and Chloride of Ammonium, alone or combined with any of the previously mentioned styptics, may be tried.

Mayo Robson has recently published his views upon the importance of resorting to surgery as soon as the hæmorrhage becomes formidable and the case has failed to respond to medical treatment, and he has given details of several successful abdominal sections. He points out the importance of diagnosing the source of the blood; where this is capillary oozing there is every hope in the success of medical treatment. Where the hæmorrhage is arterial and excessive, or recurring, a surgical consultation is imperative, and operation should be undertaken without delay. (See this question fully discussed under Gastric Ulcer, upon page 315.)

Stacey Wilson has drawn attention to the part played by varices of the œsophagus in producing hæmorrhage in cirrhosis of the liver and other affections. He dwells upon the importance of securing rest to the gullet, by prohibiting even the swallowing of ice, and he points out the uselessness of Ergot, which probably drives the blood from the arterial system into the dilated varicose veins. Nitrite of Amyl, he thinks, might act in the opposite way, by drawing a large amount of arterial blood into the capillaries.

Where the hæmorrhage appears to be owing to a blood condition, as in purpura, Turpentine, in mixture or capsules, along with Ice and Iron affords the best hope of success.

See the action of the various agents used in internal hæmorrhage, mentioned under Hæmaturia, page 353, and the method of injecting Saline Solution in severe Anæmia, upon page 41.

HÆMATIDROSIS.

For the treatment of this rare and interesting condition of "Bloody sweating" nearly every hæmostatic has been recommended. The cases have occurred so infrequently, and tend to get well if let alone, that little can be said about the value of remedies.

As a rule, in vicarious cases, revulsive treatment by hot foot-baths, sinapisms, and saline purgatives should be tried. Many of the cases occur in healthy individuals, and should not be interfered with.

HÆMATINURIA or HÆMOGLOBINURIA.

In the non-paroxysmal variety, where the urine remains during the illness constantly charged with the colouring matter of the blood, without the presence of any blood corpuscles, the treatment will embrace the remedies suitable to combat the causes of the disease. These are the ingestion of poisons, the most important of which are chlorate of potassium, carbonic, pyrogallie, oxalic sulphuric, nitric hydrochloric, and carbolic acids, poisonous fungi, phosphoretted and arseniuretted hydrogen, quinine, the poisons producing scarlet, typhoid, and other fevers, and the conditions of the blood following severe burns, fat-embolism, scurvy, &c.

Paroxysmal Hæmatinuria has a spontaneous tendency to complete recovery in all cases, and it is therefore doubtful if the many remedies said to be beneficial have the slightest influence over the condition.

Quinine and Arsenic appear to have some effect upon the urine, and the former remedy in 5 grain doses has been observed to stop the paroxysms in several cases, and in some instances they never returned afterwards. Cinchona, in doses of 2 drachms of the compound tincture, was used by Sir W. Gull.

Iron in large doses of the astringent preparations, or of the Syrup of the Iodide, or of the Sulphate with Sulphuric Acid, has been said to be valuable.

Tannic and Gallic Acids, Iodide of Potassium, Alum, Chloride of Calcium, Mercurials, Vapour Baths, Dry Cupping over the loins, with copious hot drinks containing a very little Alcohol, and many other remedies suitable in hæmaturia, have been recommended. Yeo recommends a cup of hot beef tea as a preventive on waking in the morning. The main element in the treatment is the protection of the patient from the chills which are always the cause of the attack, and to treat syphilitic subjects, in whom the disease is not very uncommon, by the ordinary remedies, viz., Mercury and Iodides.

For the treatment of the *malarial* form of the disease, see under Hæmaturia Malarial).

HÆMATOCELE.

The treatment of hæmatocele will be based upon the principles guiding the treatment of hæmorrhage into internal parts. This, for hæmatocele of the tunica vaginalis in the early stage will consist in putting the patient to rest in the horizontal position, lying upon his back, with a small light board placed across the upper part of the thighs. Upon this board or splint as upon a shelf, the enlarged scrotal tumour is laid. Iced compresses or ice tied up in gutta-percha tissue, are placed over it, or evaporating lotions upon lint are applied. Over all a cradle is placed, covered by the bed-clothes, which should be light.

A smart saline, as 1 oz. Rochelle Salt, in a tumblerful of aerated water, may be given. Leeching is rarely productive of good. When a hydrocele had previously existed, the amount of effused blood will rarely be so great as to cause the tumour to solidify; and even in cases where no effusion had previously existed, the tumour may remain fluid. Tapping with an ordinary trochar and canula is the best practice in such cases, but the surgeon should wait and satisfy himself that absorption is not likely to take place before he resorts to tapping. The operation may be repeated at intervals, with a fair prospect of cure.

Where the tumour remains hard and tense, the best procedure is to make an incision through the skin, and by dividing the deeper

layers carefully upon a director there will be no danger of wounding the testicle which is often placed in the front part of the tumour. The contents of the sac should be turned out through the large incision made into it, and after syringing, plugs of cotton wool soaked in weak Corrosive Sublimate solution may be inserted, and the sac left to granulate from the bottom. The same treatment should be adopted in fluid cysts when suppuration sets in, and it will often be advisable in such cases to insert a rubber drainage tube after turning out the suppurating contents.

In very chronic cases, where the sac walls are much thickened, after the free incision there may be difficulty in detaching the layers of partially organised clot. In such cases a portion of the thickened wall may be removed, or, as Gould recommends, the entire mass, including the testicle, may be excised.

The same measures may be employed in dealing with hæmatoceles of the cord and of the testicle proper—i.e., rest, cold, tapping or free incision, followed by Antiseptic or Iodine injections.

Hæmatocele (Pelvic) is a grave affection, and may cause death from shock unless prompt measures be adopted. The writer once witnessed such a seizure take place in his presence, a patient who was perfectly well a few moments before being stricken down as if shot by a rifle bullet.

The patient should be rapidly undressed and placed on her back upon a hair mattress, with the pelvis slightly raised by a hard counterpane folded neatly and placed under the buttocks. Collapse may be met with stimulants such as Ether, Alcohol, or Sal Volatile. Opium is the only reliable hæmostatic and restorative in such cases, and in the presence of great pain it may be given fearlessly. Small doses are useless, a tea-spoonful of laudanum by the mouth, or anus, or $\frac{1}{4}$ grain of Morphia by hypodermic injection, should be administered as soon as possible, and the effect kept up by smaller doses repeated every hour according to the urgency or severity of the symptoms. In the intervals between the doses of opium, Brandy and Ice may be freely given; afterwards Brandy or Whiskey in small quantity, diluted with iced milk, will constitute the best feeding during the early days following the seizure. As soon as possible alcohol should be stopped altogether. Local treatment should consist of cold compresses or crushed ice, folded in gutta-percha tissue or oiled silk, and laid over the lower parts of the abdomen. The vagina may be packed with ice in desperate cases. At this stage some recommend brisk purging with Calomel, Croton Oil, or strong Saline. The writer has never had the courage to try these heroic remedies. Nor has he ventured to recommend tight abdominal bandaging. A large snapism over the anterior surface of the abdomen may be employed as a revulsive measure where the collapse will not permit of iced compresses.

Cases with the gravest aspect generally recover if kept absolutely at rest and under the influence of opium, and meddling by making repeated examinations and explorations is to be condemned. Many remedies may be tried with the view of arresting the internal hæmorrhage, of these Ergot is the one most useful; it may be given hypodermically, or by the mouth in full doses. Chloride of Calcium, 20 grs. every two hours, is sometimes very efficient. Suprarenal Gland substance, in doses of 5-15 grs. will sometimes give striking results. Gallic or Tannic Acid, Digitalis, Turpentine, Acetate of Lead, Iron, &c., may possibly only tend to divert the physician's mind from the administration of opium, which, after all, is the remedy upon which the patient's salvation depends.

In the face of a rapidly increasing internal hæmorrhage the operation of opening the abdomen and securing the bleeding vessels may be weighed. If extra-uterine gestation or an ovarian varix is diagnosed this will be justified, but the hope of securing the vessels from which an ordinary pelvic hæmatocele is fed, is indeed visionary, and the vast majority of cases so treated would probably have their chances of recovery sadly minimised by such an attempt.

The subsequent treatment will be that of peritonitis, pelvic cellulitis, or pelvic abscess. When the shock and collapse have passed away, the resulting peritoneal mischief will call for sedative measures constitutionally and locally. Opium should be still our main stay, and until all danger of further hæmorrhage has passed away cold compresses are to be preferred to hot poultices. These local anodynes are invaluable at a later stage when pelvic cellulitis is established. Iodide of Potassium, or mild Mercurials, may be given with the view of causing absorption.

In the great majority of cases, the effused blood will either become absorbed, or an abscess will form which if left alone, will find its way into the bladder, bowel, vagina, uterus, or through the skin. The practice of puncturing the tumour through the rectum or vagina is followed by some surgeons, there cannot be a doubt that such a routine practice is a serious mistake. When there is evidence that suppuration is already established, and the symptoms and signs lead one to believe that there is danger of the sac bursting into the peritoneal cavity, if a bulging soft point is felt in the vagina or rectum, to wait for spontaneous rupture might be a fatal blunder. The aspirator should be discarded, and a large trochar and canula, such as is used for puncturing the bladder, may be selected, and the canula should be driven well home after the withdrawal of the trochar. Should the contents of the cavity consist of coagula, as well as puriform fluid, the opening should be freely enlarged, and the sac well washed out with warmed solutions of Corrosive Sublimate or Condy's fluid, injected from time to time through the ordinary enema apparatus to which a large, soft catheter may be attached. Vaginal puncture

is to be preferred to the anal, other things being equal. Tait has successfully operated upon several suppurating hæmatoceles by abdominal section.

HÆMATOMA.

Whether the extravasation of blood takes place under the skin over soft parts, under the skin, aponeurosis or fibrous membrane covering the cranial bones, or between the cartilage and the perichondrium, as often occurs in the ears of lunatics, the treatment is the same. The general principles which guide the surgeon in treating an hæmatocele maintain here also—rest to the injured part, the application of cold lotions or iced compresses in the earlier stages, and afterwards the influence of local remedies calculated to promote absorption of effused products. Poultices, aspiration, puncture, and incision should not be resorted to unless there be clear evidence of suppuration having taken place, as the natural tendency in the great majority of cases is for resolution to occur spontaneously. Pressure by bandaging or strapping is a valuable method of assisting nature in chronic or slowly progressing cases, and sometimes it may be found advisable to apply pressure over a spirit lotion covered in by a layer of oiled silk. The worst forms of *caput succedaneum*, and the rarer and more serious *cephalhæmatomas*, will almost invariably yield to expectant treatment.

When suppuration occurs, aspiration is generally advised. It will be found much more satisfactory to make a *free* incision into the centre of the swelling, press out the contents, and wash out the cavity with weak Sublimite Solution (1 in 5000), or swab it out with Lint soaked in strong Carbolic Acid or Iodized Phenol, and leave in a drainage tube under antiseptic dressings.

Hæmatoma auris, if let alone and protected from injury, always yields to expectant treatment, and rarely requires incision, lotions, poultices, or pressure.

Hæmatoma of the labium may be best treated by cooling antiseptic lotions, and as soon as suppuration occurs free incision with antiseptic precautions.

HÆMATURIA.

It is useless to attempt to treat this condition until the source and cause of the hæmorrhage are determined. Though this may in some cases be found difficult or impossible, nevertheless the first step should be to test the urine microscopically and chemically, investigate its colour, reaction, and appearance immediately after micturition and upon standing, and to carefully examine the shape, diameter, and colour of all clots by causing them to float in water. By examining the bladder with the cystoscope, the exact site of the hæmorrhage may be demonstrated.

A careful analysis of the history and symptoms in many cases will show whether the blood is urethral, vesical, or renal.

Having made the diagnosis of the exact source of the hæmorrhage, treatment may then be directed to the disease of which it is the symptom. If from the urethra the passage of as large a sound, catheter, or even rubber catheter, as the canal will admit, should be effected, and pressure made from without by bandage or strapping, and ice may be applied over the bandage.

If from the bladder and the cause cannot be immediately removed (stone, ulcer, cancer, tumour, &c.) rest in the horizontal position, and the free use of ice or cold in the rectum, vagina, to the perineum, or over the pubes. Leiter's tubes may be applied to any of these regions with advantage. Should there be evidence that the hæmorrhage, though vesical, is probably vicarious, as may be met with in cases of hæmorrhoids or suppressed menstruation, the hæmaturia should not be interfered with till the suppressed flux is established. In such cases leeches may be applied, and smart purges administered. Notwithstanding rest and the free application of cold and ice, and the use of the internal hæmostatics to be immediately mentioned, if the hæmorrhage should continue, resort must be made to vesical injections.

The most efficacious and the safest is iced water containing in solution Alum, 25 to 40 grs. in each pint. The use of vesical injections will end in disappointment if the bladder be not first emptied with a large-eyed catheter of soft rubber connected with a Clover's or ordinary lithotomy suction apparatus and the most thorough irrigation effected before their introduction. This plan will be imperative if retention of urine from clots exist.

Other hæmostatics are injected—Nitrate of Silver (10 grs. to 20 ozs.), Hazeline (1 to 2), Solution of Perchloride or Pernitrate of Iron (1 drachm to 20 ozs.). The writer has treated vesical hæmorrhage in one case by the injection of Castor Oil in quantities of 2 to 5 ozs. successfully.

Denny advises, after complete irrigation, the injection of about 3 oz. of solution of Nitrate of Silver ($\frac{1}{2}$ gr. to 1 oz.). This should be retained for a few minutes; every third or fifth day the injection should be repeated and the solution increased in strength gradually till 10 grs. per oz. is reached. At the same time the period during which the solution is to be retained is also cautiously increased. This is probably the best treatment in all cases of persistent bladder hæmorrhage.

Harrison treats severe hæmaturia from enlarged prostate by emptying the bladder, and tying in a soft catheter, whilst pressure is made from without as in a case of post-partum hæmorrhage. As long as the bladder is capable of exercising pressure there is little danger in these cases, but when from atony of its walls it is unable to contract completely the above means is the only way to stop what may become a fatal hæmorrhage.

Internal hæmostatics may be employed at the same time as the injections are being administered.

Where bladder hæmorrhage continues, the best procedure is to open the viscus above the pubes, and deal with the cause. Fenwick and others have reported many brilliant successes by this method. The cause of the bleeding can sometimes be completely removed, as in the case of villous and other growths.

Hæmaturia may be the only symptom present in scurvy, and if recognised and treated by fresh vegetables it yields immediately. Barlow points to similar successful treatment in infants fed upon preserved foods where the hæmaturia may be the most obvious symptom of scurvy or rickets caused by the diet.

When hæmorrhage is of renal origin, cold, by means of ice-bags or Lister's tubes, applied to the loins may be tried.

If the bleeding be the result of the ingestion of irritants like cantharides or overdoses of turpentine, these drugs should be immediately discontinued.

Rest in the horizontal position is even more imperatively demanded than in the management of vesical hæmorrhage.

Where the hæmorrhage is the result of a general renal congestion, dry Cupping of the loins, Hydragogue Cathartics, strong Sinapisms, or local Wet Packs or Mustard Packs may be tried. These are indicated in the treatment of hæmaturia coming on in the early stages of acute Bright's disease where the application of cold is fraught with some risk. Such cases, however, seldom require treatment for the hæmorrhage.

Internal hæmostatic remedies may be employed where the quantity of blood coming from the vesical or renal region is such as to weaken the patient, but little faith need be placed in these drugs, except in Chloride of Calcium in 30 gr. doses every four or six hours for six or eight times.

Opium or Morphia will be beneficial where there is no albumin.

Ergotin (5 grs.) may be injected deeply into the buttock or loin; some surgeons prefer Sclerotic Acid (1 gr.).

Alum, Gallic and Tannic Acids, Rhatany, Kino, Catechu, Matiko, and Cinchona are generally useless.

Acetate of Lead (3 grs. with $\frac{1}{2}$ gr. Opium) every three hours and large doses of the astringent Iron preparations well diluted, are valuable where purpura exists.

Turpentine (5 minims) or Creosote (2 minims) are more likely to produce some effect upon the hæmorrhage.

Digitalis has occasionally given good results, and so has Indian Hemp in an unexpected manner, but both are very uncertain in their action.

Hamamelis is lauded, but the writer has rarely seen it do any good, and Chimaphila seems to rest upon an equally undeserved reputation.

The best results that the writer has witnessed in the treatment of renal hæmorrhage (before the introduction of Chloride of Calcium) he has obtained by Jaborandi in doses of 30 to 45 minims of the tincture. He was led to employ it in hæmaturia after

noticing its effects upon bloody urine when given in Bright's disease with the intention of producing sweating and elimination of urea. He has satisfied himself about its great value in many forms of renal hæmorrhage.

Recently the hypodermic injection of Gelatin solution has given good results.

Suprarenal Extract in 5-10 gr. doses promises to become the best routine remedy in internal hæmorrhage, especially from the urinary tract.

HÆMATURIA (Malarial).

This condition is known also under the names of Blackwater Fever, Bilious Remittent and Bilious Hæmaturic Fever, Hæmogloburic Fever, Hæmorrhagic Fever, and Malarial Hæmoglobinuria. It may be safely said that there is no other disease about whose treatment such widely divergent views are held and promulgated, and this may be explained by a glance at its supposed pathology. A large number of observers in different parts of the world maintain that the condition is simply a symptom of poisoning by quinine which has been given for the malaria which is invariably present. Thus Stephens quite recently states that "blackwater fever is essentially a malarial infection in which quinine is the most constant, immediate determining cause of intoxication. Protection from malaria will insure protection from blackwater fever. Sambon also quite recently affirms that "the connection of quinine and blackwater fever is not one of cause but merely one of coincidence." When these divergent views are applied to treatment the case is hopelessly confusing and almost paralysing. Most British physicians practising in malarial regions regard quinine as a specific, notwithstanding that others hold that its action is most injurious. It seems therefore, almost certain to the writer that the disease is one of mixed infection, and that the question will only be cleared up by the discovery of a specific parasite which attacks in company with the malarial one. In the early stages when the malarial parasite is supreme, quinine may be most beneficial; in the later stages when this has been destroyed by the drug or by the phagocytes, quinine may be injurious. This view will give a safe working hypothesis for the practical therapeutics of the malady. The patient should be put to bed at once, and when seen early should have quinine and diaphoretics, with decoction of fresh lemons, Calomel and saline purgatives. The symptoms as they arise must be treated upon ordinary therapeutic principles. Pain should be treated by hot fomentations to the kidney, spleen and liver. The great danger is suppression of urine which occurred in the only two cases seen by the writer, and which were uninfluenced by Pilocarpine and the warm pack. The treatment affording the best hopes of success is the injection of normal Saline solution hypodermically and by the colon.

HÆMOPHILIA.

This being a congenital condition or a diathesis handed down by hereditary transmission it cannot be expected that treatment by drugs will alter the condition of affairs to any appreciable extent. Everything that will raise the standard of health and maintain it at its greatest height will be needful. Good food, healthy clothing, abundance of ventilation, free open-air exercise and outdoor occupation, freedom from worry and pressure, a warm climate, and very regular habits may do much to modify the diathesis.

Preventive treatment in the way of avoiding injuries, wounds, abrasions, &c., must be a life-long object of care and solicitude. No surgical operation should be undertaken. Many deaths have followed the skilful extraction of teeth, and serious results have followed the most trivial scratchings.

When bleeding has already occurred the treatment is most difficult, and very firm pressure and styptics may be promptly tried and may succeed in staying off danger. Absolute rest in bed is essential, and internal hæmostatic remedies must be pushed to the extreme. By far the best of these is the Chloride of Calcium in 20 gr. doses in water. Iron, Lead, Turpentine, Ergot, Alum, Tanic and Gallic Acids, Creosote, and Digitalis may be tried. Iron is the best of these remedies, and Dr. Harkin has recorded good results from the combination of Chlorate of Potassium (5 grs.) and Tincture of Iron (20 minims), four times a day in glycerin and water. Recently inhalation of Oxygen, the administration of Thyroid Extract, and the injection of Horse's Serum have been reported upon satisfactorily. Sometimes after the failure and discontinuance of all remedies, the hæmorrhage ceases when death is expected, and the patient makes a tardy recovery.

Where the hæmorrhage proceeds from the socket of a recently extracted tooth the cavity should be packed with Puff-Ball (*Lycoperdon Giganteum*), and a pad of wool placed over the depression or gap in the dental arch and the jaws firmly bandaged together, or pressure may be continuously kept up by a plate held in position over the pad by attachments to the surrounding sound teeth till all trace of danger passes away.

Wounds may be treated in a similar way by laying upon them a pad of Puff-Ball and bandaging firmly over the bleeding surface, which should, if possible, be kept elevated.

Epistaxis should be treated by the Puff-Ball and the other measures described under Epistaxis, and McKenzie has reported success from the local application of Suprarenal Medulla.

The galvanic-cautery may be tried in some instances, but Wickham Legg states that whilst styptics are worthless, the use of the hot iron and of the Perochloride of Iron is especially to be avoided. Transfusion should always be performed when everything else fails, and the patient shows signs of approaching death.

It should not be thought of as long as there is a fair prospect of the hæmorrhage ceasing, as the wounds produced by the operation become serious additional elements of danger. All authorities agree in forbidding marriage, and this should be strongly insisted upon with women bleeders, or female members of bleeder families who may not themselves have shown evidence of the diathesis.

Vaccination should be performed with great caution, and the punctures made as superficial as possible. Death has been known to result from the operation.

For the joint affections common in bad cases of the diathesis, absolute rest and the application of cold evaporating lotions, followed by dry heat to the affected joints, are indicated. Splints are necessary in very severe cases to ensure thorough immobility.

Extravasations of blood, bullæ, or abscesses should never be interfered with surgically. Ligature of arteries going to the bleeding locality is useless.

HÆMOPTYSIS.

The vast majority of the cases of the present affection will be found to arise during the progress of tubercular phthisis. In discussing the question of treatment, it is assumed that the blood is proceeding from small vessels cut across or ulcerated in the necrotic process associated with the softening of tubercular nodules, or that the hæmorrhage is coming from the bronchial capillaries, or from minute aneurismal dilatations.

Rest is the first essential. The patient should be put to bed in bad attacks. He may be allowed to have his head and shoulders elevated with a bed rest. All food should be liquid and cold. Milk is ample for the first few days. Alcoholic stimulants should be avoided in all cases, unless where there is great shock and prostration. Some authorities insist upon a very *dry* diet.

Ice sucked in the mouth, or tea-spoonfuls of iced water swallowed, afford a pleasant way of assuaging thirst, relieving cough, and checking hæmorrhage.

Speaking should be indulged in only when absolutely necessary.

Counter-irritation, by a poultice of mustard made into a paste with cold water, should be placed upon the front of the chest. Hot poultices should be avoided, and warm applications tend to encourage the hæmorrhage. If the quantity brought up is alarming, a large bladder of ice should be laid upon the front of the chest, or wetted towels, between the folds of which pieces of ice or a mixture of crushed ice and salt is placed, may be laid on the thoracic wall.

The good to be got from applications of ice to the chest occurs at once, or soon after the chilling of the skin. If the cold be continued for any length of time more harm than good is certain to result, as has been demonstrated in Rossbach's experiments. The writer is satisfied that the bleeding is made worse if the iced

compresses are kept on for more than 15 or 20 minutes at a time. Dry cupping has been found useful sometimes.

The room should be kept cool and well ventilated, if possible without the patient being directly exposed to draughts. A large vessel filled with hot water should be placed under or about the bed, and into this Turpentine should be poured in small quantities at frequent intervals, the object being to keep the air of the room saturated with turpentine vapour. The drug may be poured upon cloths suspended in the air, or it may be sprinkled upon saw-dust or pine shavings in a safe corner of the room, away from the danger of ignition. This is the routine practice of the writer, and in mild cases little else need be done. The turpentine vapour seldom proves disagreeable, and it is an excellent antiseptic and hæmstatic, and in some cases exercises considerable soothing influence over the cough, which so often complicates the treatment of the affection.

Of internal remedies, Opium is the most valuable, unless where there is very profuse expectoration, associated with great weakness. It is in the early stages of phthisis, where hæmorrhage may be abundant, that its use is best marked. Its contra-indications are the same in hæmoptysis as in bronchitis, and in the later stages of phthisis its effects should be carefully watched. A full hypodermic dose of Morphia often acts well when not contra-indicated.

The effects of the usual hæmstatic remedies (as mentioned under Hæmaturia, Hæmatocele, &c.) are very uncertain and unsatisfactory. Chloride of Calcium, in 15 gr. doses every 3 or 4 hours, by increasing the coagulability of the blood, assists the sealing up of the open vessel, and the hypodermic injection of Gelatin serum (2 per cent. gelatin with common salt) acts in the same way, but less effectively. Schafer's suggestion of injecting Suprarenal Medulla may prove valuable, and already reports of its rapid and effectual action have been made.

Ergotin should be tried in severe hæmorrhage from the lungs, and no time should be lost in injecting deeply into the tissues one full dose, say 15 minims of the B.P. hypodermic solution. Its effects may be kept up by small doses given by the mouth. It does not interfere with the action of other remedies of the same class, and, after the full hypodermic dose has been administered, the patient may, in desperate cases, begin with half-hourly doses of some other remedy.

Alum may be given in doses of 5 grs. every 15 or 30 minutes: it may be well dissolved in water, and 10 minims of Dilute Sulphuric Acid can be given with each dose.

It is idle to prescribe a remedy to be given every 4 or 6 hours to a patient pumping up blood every few minutes. He expects to be dead before the second dose falls due. The moral effect of having his remedy in such serious cases at hand, and to be used every 15 or 30 minutes, helps to give him countenance, and tends

to allay dread and excitement, which are highly injurious to him. It is wise, therefore, to order one full dose of the remedy in a table-spoonful of mixture for example, and direct a tea-spoonful of the same mixture to be given every quarter of an hour afterwards, till the hæmorrhage diminishes, 30 grs. of Tannic or Gallic Acid, dissolved in 1 oz. of water, may be given when the hæmoptysis begins, and $\frac{1}{4}$ of this amount, in a tea-spoonful of water, may be given every 20 minutes afterwards.

The following empiric combination may be tried :—

R. *Ext. Ergotæ Liq.* 3vi.
 Acidi Gallici 3ii.
 Liquor. Morph. Hydr. 3ii.
 Tinct. Hamamelidis 3j.
 Aquæ Dest. ad 3viij). *misce.*

Ft. mistura. Cpt. 3ss. omni hora p. p. n.

Acetate of Lead may be given (with a little Vinegar and Morphia) in doses of 1 grain every hour, for 8 or 10 hours.

Turpentine, in capsules—20 minims—may be given at first, and 5 minims every half hour afterwards for 6 doses. It may also be given in syrup and water, with a little Ether.

Digitalis is much recommended, but the writer believes that, in severe and urgent cases, it is much worse than useless. It takes many hours before a safe dose exerts its full action upon the heart and vessels, and to trust to it in emergencies, where every minute is of value, may be a fatal mistake. It is a remedy of great value in hæmoptysis of small amount extending over many days.

Where there is febrile action in strong subjects, Aconite or Veratrum Viride may be given in small repeated doses. Tartar Emetic and Ipecacuanha have been given, with somewhat similar intention, to act as depressants.

Nitrite of Amyl has sometimes been found to act with great rapidity, by dilating the vessels it may give great relief to the smaller arteries and veins, and, if at hand in severe cases, it should get a trial.

Chloride of Barium acts like Digitalis, and has been recommended; it is of doubtful value.

Chloride of Sodium is always at hand, and it sometimes has some influence over hæmoptysis, 2 tea-spoonfuls may be dissolved in a tumblerful of cold water, and 1 table-spoonful of this solution may be given every 5 minutes. The Chloride of Ammonium is equally efficacious in similar doses.

Cayenne Pepper has been recommended in 5 to 10 gr. doses by Chéron, who believes that it acts like Ergot. The writer has no experience of its action.

Hamamelis Virginica or its distilled extract *Hazeline*, has been reported by very many to be a specific in hæmoptysis and internal hæmorrhages. There is still room for doubt about this action of the drug. *Hazeline* may be given in doses of $\frac{1}{4}$ to 1 drachm, or more; it can do no harm in any case.

Astringent Iron preparations are valuable, and may be given without fear if well diluted, 30 minims of the tincture of the perchloride, or 3 grs. of the sulphate, or the acetate given as *Busham's mixture*, are excellent hæmostatics.

Belladonna or *Atropia*, the latter hypodermically, are solely relied upon by some physicians.

Pyrogallie Acid, though a dangerous poison, has been successfully used in hæmoptysis and internal hæmorrhages, $\frac{1}{4}$ grain every hour for 8 or 10 doses is a fair dosage.

Antipyrine has been reported as very successful in several cases.

Oxide of Silver (1 gr. every 2 hours), *Sulphate of Copper* ($\frac{1}{4}$ gr. every hour, or 5 grs. as an emetic) *Bromide*, *Nitrate*, and *Chlorate of Potassium*; the entire army of vegetable astringents, including *Matico* and *Larch*; *Arnica*, *Bryonia*, *Hydrastis*, *Copaiba*, and *Cannabis Indica*, have all been recommended and tried with varying successes scarcely warranting further trials.

Shoemaker speaks highly of *Geranium Maculatum*.

Sprays and inhalations are of little use, if used strong enough to have any effect they excite coughing.

Revulsive measures must not be omitted from the list of remedial agents. A smart Saline often acts in a surprising manner. The writer has witnessed, many years ago, in the practice of an old physician, startling results from blood-letting. In one case of pretty advanced phthisis, hæmoptysis had been continuing for many hours, and the patient was showing signs of sinking when the physician, without any apparent hesitation took out his lancet and struck a large orifice in the vein at the elbow, from which a gush of blood freely flowed. The hæmoptysis instantly stopped, and the patient made a good temporary recovery. Though this was more than thirty years ago the writer has never had the courage to try it again. Saline injections may be needed to combat the anemia which results in severe cases.

HÆMORRHAGE.

The treatment will depend upon the nature of the disease or injury which has led to the opening of the vessels from which the blood is poured. In internal hæmorrhage the lines of practice will be found enumerated under the various headings of *Hæmatocele*, *Epistaxis*, *Hæmaturia*, *Hæmophilia*, *Hæmoptysis*, *Hæmatemesis*, *Anæmia*, &c.

In external hæmorrhage the general treatment will be the same as for internal hæmorrhage.

Syncope collapse or shock may result where the bleeding has been extensive, and it may be the first duty of the surgeon to attend.

to this symptom. In this stage, bleeding has practically stopped, and nature is perhaps at the moment forming coagula to seal up the open vessel. If the surgeon could be sure that the collapse would certainly pass off by waiting, he should not use active measures to restore the circulation. The collapse or syncope may, however, be fatal if vigorous measures be not immediately undertaken to excite reaction. The skill, coolness, and sound judgment of the surgeon will be required to decide how far he may be justified in an attempt to allow nature to stop the open vessel or to establish reaction at once and tie the bleeding point himself. If the bleeding point is beyond reach, and the hæmorrhage difficult to control, to hasten reaction by pouring down the patient's throat large quantities of alcohol may in some cases be the worst possible thing to do. Stimulants must be freely given in desperate emergencies and when life is placed in great jeopardy by the collapse. The hypodermic injection of Ether or *Sal Volatile* or the rectal administration of Brandy, may be required in some cases. The horizontal position must be rigidly enforced, and all operative procedures must be carried out in this position after extensive bleedings. The head should be kept low, and a free current of cold fresh air may be permitted to blow over the face. Strong Ammonia or Acetic Acid to the nostrils, or a dash of cold water to the face, often restores consciousness in such cases. By elevating the lower extremities the blood may be caused to flow towards the empty heart, which may be thus stimulated to renew its pulsations, then pressure may be made upon the abdominal aorta or upon the femoral arteries, or a ligature or tourniquet may be applied to the limbs, with the view of confining the blood to the brain and heart. As a last resort in desperate hæmorrhages an elastic bandage may be rapidly applied to one or both lower limbs, and an Esmarch's rubber cord tied round the thigh, near the groin.

Injection of large quantities of saline solution or transfusion may be resorted to. (See under *Anæmia*, page 41). Such procedures will seldom be required in private practice but two years' experience as resident surgeon in a large hospital brings to mind many cases where patients were brought in a collapsed state, and where the promptest action was necessary to save life. A minute's delay sometimes may be fatal. The most profound collapse and syncope have been witnessed by the writer in hæmorrhages following innocent-looking punctures of the venous plexus about the orifice of the vagina, caused by fractured chamber-pots, &c. Such cases are not brought to hospital till almost too late.

If pressure can be made upon the bleeding spot there is no danger to be feared from active attempts to establish reaction. Once the bleeding point is secured, such attempts should be made without delay.

In securing a bleeding vessel, certain cardinal principles should not be forgotten. If an artery be wounded, the wound in the skin

and soft parts if necessary should be freely enlarged and a ligature applied above and below the bleeding point in the vessel. Should the vessel be cut across, both its proximal and distal ends must be separately ligatured.

Where the vessel is a small one or the stream of blood limited in extent, firm pressure by a graduated compress and a skilfully applied bandage may be sufficient. In some cases this will be the best temporary treatment till reaction has been fully established, when a deliberate dissection subsequently, after the application of an Esmarch's bandage will enable the surgeon to secure the wounded vessel, which could not be found at the time of the active hæmorrhage. It may be even necessary in some cases to give up the attempt to find the injured artery, and to ligature the trunk higher up. The writer has successfully done this in cases of cut-throat, where to waste time hunting for the divided branches would have led to fatal results. Acupressure with a figure of 8 ligature may be the most rapid and complete measure in some cases. Torsion may be applied to the divided vessels, but it will be generally found that in these cases the ligature is more satisfactory.

Veins may be dealt with in the same way as arteries but often the elevation of the limb and moderate pressure will answer all purposes, as in the profuse hæmorrhages sometimes following varicose ulcers of the leg.

Styptics are not to be relied upon though the writer has been able to control formidable hæmorrhages, with almost magical rapidity, by thrusting a mass of the Puff-Ball (*Lycoperdon Giganteum*)—see 7th edition of "*Materia Medica and Therapeutics*," page 560—into the centre of a deep, spouting wound. The Penghawar Djambe, or Paku-Kidang, appears to act in a similar way—see same volume, page 578).

Perehloride, Sulphate or Pernitrate of Iron, Matico (in powder), Ice, Alum, Tannic Acid Richardson's or Ruspini's Styptic Collod, cauterisation by actual, galvano- or thermo-cautery, Turpentine, hot water (at a temperature of 120° to 125° F.), and many other astringents have been recommended. In urgent cases, where bleeding is profuse, their trial will be a waste of precious time, though in trivial bleeding they will often meet all requirements. Their use prevents union by first intention.

For capillary bleeding following extensive superficial wounds, operations or flap amputations, the free exposure of the oozing surface to a stream of cold air or iced water, followed by moderate pressure, is generally all that is required. Such treatment is, however, generally useless till all clots have been removed and every trace of blood sponged from the weeping wound.

The treatment of the wound after the successful closure of the bleeding vessels is to be conducted upon general surgical principles, and the constitutional treatment is to be based upon the lines laid down for the management of *Anæmia* (page 40), modified by the complications present in each case.

When active external hæmorrhage is going on, it is scarcely necessary to say that internal hæmostatic remedies, such as may be valuable in hæmoptysis, &c., are of very little use but the value of Chloride of Calcium by its power of increasing the coagulability of the blood must not be lost sight of, and Suprarenal Extract is valuable, especially where it can also be used locally. The treatment of wounds and injuries in subjects of the hæmorrhagic diathesis will be guided by the principles enumerated under Hæmophilia.

HÆMORRHAGE FROM THE BOWELS—See *Melena*.

HÆMORRHAGE, Post-Partum.

The treatment should be, in the first instance, *preventive*. Post-partum hæmorrhage is a rare event when the cautious physician is present and directs or carries out the necessary manipulations of the uterus during and after the completion of labour.

After the complete expulsion of the child the uterus should be grasped from above by the left hand of the accoucheur, and pressure steadily maintained after the removal or expulsion of the placenta. This pressure may, in the majority of instances, be very slight, just enough to enable the operator to feel confident that he can speedily apply considerable force at a second's notice should the uterus show signs of relaxing under his grasp. The thumb should be placed in front, and the fingers dipped down deeply into the relaxed abdomen, so as to seize and squeeze the uterus as firmly as if the operator had the organ in his hand outside the body.

Most authorities urge that the placenta should not be expressed for at least half an hour after delivery, and many recommend that double this period should elapse before resorting to removal.

The habit of applying the pad and binder immediately after the removal of the placenta should be condemned. It has been the cause of many deaths from hæmorrhage. With the binder *in situ*, as a rule, little can be known about the state of the uterine contractions. Under a well-adjusted bandage it is quite possible for the uterus to relax and fill with blood, without giving any warning to the over-confident attendant.

The young accoucheur will never regret the routine practice of keeping up a close watch upon the state of the uterine contractions for a considerable period after the expulsion of the placenta, before having the binder applied. It will be a good practice—(1) Never to apply the binder till after the child has been bathed and dressed; (2) to give one full dose (30 to 40 grs.) of Ergot immediately after or before the expression of the placenta; (3) to count the pulse from time to time—a pulse of 100 often indicating or forecasting a smart hæmorrhage, though the uterus may be felt quite hard under the fingers; (4) the accoucheur should not give up pressure or kneading till the uterine contraction has become

permanent; (5) it is a good routine practice to put the child to the breast as soon after delivery as possible, in order to excite reflex uterine contractions.

Tarnier recommends that where the history leads the accoucheur to expect hæmorrhage he should guard against uterine inertia by rupturing the membranes before the os is fully dilated.

Where hæmorrhage has already occurred it should be stopped by immediately grasping the uterus as just described, and by alternately kneading and squeezing the relaxed organ all clots are expelled, and further hæmorrhage for the moment prevented. If the placenta has not been previously expelled the kneading and strong compression exercised by the fingers will probably cause its ejection. Should it still remain in the uterine cavity and the hæmorrhage continue, its removal becomes imperative. This is done by the introduction of the sterilised or rubber-gloved hand into the vagina and uterus and the peeling off of the placenta from the uterine surface. After the introduction of the hand the cavity should be washed out with some weak antiseptic liquid.

It is well to remember that partial attachment of the placenta to the lower uterine segment is a common cause of hæmorrhage, the upper portion in the superior segment of the uterus being firmly attached whilst the blood flows from the partially attached lower part of the placenta. In these cases operative interference may be demanded without delay.

Should the hæmorrhage continue after the extraction of the placenta and all the clots found in the uterus and vagina, notwithstanding the steady, firm kneading from above, the physician may again introduce his freshly sterilised right hand into the relaxed uterine cavity, and pressing his clenched fist against his left hand applied above, he may firmly squeeze, knead, or grind the uterine walls between, till firm contraction is established. In one apparently hopeless case the writer introduced a large sponge soaked in strong vinegar and withdrew his hand, keeping up strong pressure from above and squeezing both uterus and sponge till permanent contraction was aroused.

A less formidable procedure is to introduce the hand into the vagina and press the uterus firmly between it and the hand applied as before outside and above. By directing the tips of the fingers into the anterior or posterior vaginal *cul de sac*, the anterior and posterior uterine walls may alternately receive the chief portion of the pressure.

Herman follows the plan of inserting the left hand into the vagina and closing it by bending the fingers into the palm, the right hand grasps the uterus from above and holds it pressed against the firm resisting surface formed by the closed fingers and volar prominences of the left hand, and in this way the whole of the uterine body can be firmly compressed. This continuous compression, he affirms, is the best of all known treatments of

post-partum hæmorrhage, and the writer believes that if properly carried out no other need ever be used.

Ice may be applied in either hand, or a large rounded lump may be inserted into the uterine cavity. Cold or iced water injections or irrigations may be employed, and iced compresses may be applied to the genitals or abdomen. Whilst keeping up compression for any length of time it is a good plan for the accoucheur to have a large jug of iced water in which he can immerse one hand whilst resting it after the muscular exertions entailed by the kneading process. The cold hand can then grasp the uterus, whilst the other is in turn dipped into the ice water. In this way, if no assistance is forthcoming, compression may be kept up for a considerable period. The relaxed organ should not be entrusted into the hands of an ordinary nurse unless the physician can place the utmost reliance upon her skill and steadiness.

Hot water injections or irrigations of the interior of the uterus act as powerful local hæmostatics and cause generally speedy and firm contraction. The temperature should be between 115° F. and 120° F.

Vinegar, or diluted Acetic Acid, as mentioned, may be injected or introduced upon a sponge into the uterine cavity. The introduction of sponges, owing to the difficulty of sterilising them, should never be resorted to unless in the absence of all substitutes.

Alum, Tannin, Alcohol, Acetate of Lead, Hamamelis, Tincture of Iodine, and many other substances have been recommended for local application; but if the bleeding has resisted the previously mentioned measures, the employment of these is only waste of precious time.

Schafer recommends the injection of 30 grs. of dry medullary substance *Suprarenal Medulla* infused in 20 oz. water, sterilised by boiling, and injected into the uterus whilst fairly hot.

As a last resort, the physician will proceed to inject into the uterine cavity a strong solution of Perchloride of Iron. One part of the solid crystalline perchloride in 10 parts of water is the usually accepted strength. The B.P. diluted solution or the B.P. tincture may be employed. Weaker solutions (half the above strength or less) may be used, and Spiegelberg strongly warns the practitioner against employing the concentrated solutions, which he affirms are exceedingly dangerous. He uses a solution composed of a table-spoonful of the strong solution in 17 of water. The writer has injected the strong solution (1 of the solid in 10) without ever witnessing bad results, but his experience is too limited to be of value, though he would remark that as the injection of iron should never be undertaken except as a *dernier ressort* in cases of threatening collapse, it would be well not to waste the time spent upon trying a very weak solution, but in desperate cases inject the 1 in 10 solution.

Weak injections might be profitably employed in the treatment of cases where persistent oozing results from a doughy, imperfect

contraction of the uterus. Some authorities condemn the injection of the iron solution, but recommend that the interior of the uterus should be swabbed out with it by means of cotton-wool soaked in the solution.

There is a growing feeling against iron injections, as the liquid may pass up the tubes and cause a fatal peritonitis, or it may cause clots which may afterwards be detached and reach the heart, it is also said to lead to sepsis by the slow decomposition of the altered blood left in the uterine cavity. It is now generally abandoned for the next method of treatment, viz., plugging of the uterus with Iodoform or Carbolic gauze. Three gauze bandages, four inches wide and each four yards long, will be necessary. The hand is passed up to the fundus, and with a long uterine forceps a large bunch or pad of the gauze is pushed up to it and held against the fundus till subsequent additions are pushed up beside it, and before an entire length gets packed into the cavity its end is tied to the beginning of the next roll, which is to be inserted in the same way. Boric Acid, Iodoform, or other antiseptic is to be freely applied to the gauze during the plugging. The uterus and vagina will thus be completely filled by one continuous strip of gauze, which can be gently pulled out after about twelve hours. If this operation be boldly carried out, and no room be left for bleeding between the uterus and the plugging, it must be successful and practically free from after dangers. The gauze, acting as a foreign body, will excite firm contraction, and by direct pressure will prevent all possibility of hæmorrhage. In the absence of an antiseptic gauze, strips of calico, linen, or other soft fabric, sterilised by boiling, will answer all purposes.

Gelatin Serum (5 oz. 2 per cent. Gelatin solution and '8 per cent. Chloride of Soda) may be injected, but the hæmostatic action of Gelatin may be best obtained by packing with Gelatin gauze.

The drawing down of the uterus by a vulsellum, which is often necessary in the above methods, is of itself a powerful means of arresting the hæmorrhage by the kinking and compression of the uterine arteries, and some authorities recommend this to be carried to the extent of producing inversion.

Only three internal remedies can be said to be of any use; these are Chloride of Calcium in 20 gr. doses, which is probably too slow in its action for a desperate emergency, and Ergot, which should be administered immediately after the bleeding has started, even if it had been previously administered during the labour or afterwards as a preventive of hæmorrhage. Full doses must be given, and there is no preparation equal in promptness to the freshly-prepared infusion, save the hypodermic injection of Ergotin. This latter should be always employed in urgent cases; 10 to 15 minims may be deeply injected into a muscle, or even into the uterine walls in desperate cases, and may be repeated in from 15 to 20 minutes; 1 drachm of Ergot, made into an infusion, may be administered by the rectum; 4 or 6 drachms may be

given in a severe case. This remedy should be always employed in conjunction with the local manipulations already described. The third remedy is Suprarenal Extract, which may be given in 10 grain doses.

Quinine is sometimes used, but must be given in very large doses in such cases; 15 to 20 grs. in water paper may be administered. It is apt to cause vomiting, and its action is slow. Some physicians maintain that it is a good prophylactic against hæmorrhage when given during or immediately after labour has set in.

Pressure upon the abdominal aorta, bandaging of the lower extremities, and the various measures mentioned upon page 360, may be tried in desperate cases. Collapse must be met by stimulants, frictions, &c., as described upon page 156.

After the firm and permanent contraction of the uterus is established, a well-adjusted pad should be placed above the fundus of this organ, and a tight abdominal bandage should be applied, and the patient closely watched till reaction has completely set in. Transfusion and other remedies for the acute anæmia following extensive bleedings are enumerated in the previous article and under the heading Anæmia, but the hypodermic or intra-venous injections of weak Saline Solutions (Chloride of Sodium, 1 drachm; water, 1 pint) give the best results, and meet every requirement of the case. Many authorities recommend the administration of the Saline Solution by injecting it into the colon, thus avoiding the danger of forcibly expelling uterine thrombi and of causing sudden over-strain of the cardiac muscle.

HÆMORRHAGE FROM THE STOMACH—See under

Hæmatomesis.

HÆMORRHOIDS.

There are few affections in which there is greater scope for the intelligent and successful use of remedial, palliative, and preventive measures. The physician is generally consulted during, what is called by the patient, "an attack of piles," and it will commonly be found, as pointed out by Curling, that in these cases a varicose condition of the veins of the lower part of the rectum or anus has existed for years without causing any inconvenience. The "attack" has followed some indiscretion in diet, excess in drinking, constipation, or other violation of some fundamental law of health. It may, therefore, be advisable to consider at this place

Preventive treatment.—Sedentary habits should be given up for active, open-air exercise when possible, too much standing being as prejudicial as too much sitting. Clothing should be warm but not excessive, and special care should be exercised over the covering of the feet and lower extremities. Damp and cold to the feet being especially injurious.

Constipation must be prevented by the various means enumerated under this heading upon page 164, and the evil influences of pressing or straining whilst sitting upon the ordinary ill-devised, modern water-closet seat, as previously mentioned, must be guarded against. Constant use of purgatives is a serious evil. One point should always be insisted upon by the attendant—it is of vital importance—i.e., that the prolapsed piles, or varicose mucous membrane, should be gently pushed up after every evacuation. A great deal of the ordinary hæmorrhoidal trouble is produced by the constriction of the external sphincter upon the prolapsed tumour, causing irritation, inflammation, thrombosis, and other mischief. This may be prevented or warded off for a long or indefinite time by attention to the above rule. Verneuil treats hæmorrhoids by stretching without rupturing the sphincter by slow dilatation with the fingers; this completely cures the spasm which he maintains is the chief agent in the condition.

Diet should be varied and regular, excess being avoided; alcohol in every form is injurious except in very small quantities. As a rule, the diet best suited to the hæmorrhoidal patient is the diet which keeps his bowels in the most desirable condition. A table-spoonful of pure Olive Oil in the morning, or at the conclusion of dinner, sometimes keeps the motions agreeably soft. Brunton recommends Aloin in doses of $\frac{1}{4}$ gr. several times daily. Orange marmalade or stewed fruits are valuable, but figs in every form should be prohibited, as their minute, spherical seeds often lurk in the recesses between the lobules of the hæmorrhoidal tumours, and seriously aggravate the tenesmus and discomfort.

Absolute cleanliness and the use of the softest paper or sponge are daily essentials.

Bladder, urethral, renal, pelvic, hepatic, intestinal, cardiac, pulmonary, and other causes of increased blood pressure in the inferior hæmorrhoidal veins must be attended to.

As a preventive and curative measure there is nothing more valuable than small injections of cold water. 5 to 10 ozs. thrown up act as a tonic to the relaxed membrane and blood vessels, relieve tenesmus and constipation, stop hæmorrhage, and promptly put an end to pruritus.

The Confection of Pepper (Ward's Paste), Copaiba, Confection of Senna, Sulphur, Castor Oil, Tar, Glycerin, Turpentine, Hamamelis, Ergot, Cubebs, Pulv. Glycyrrhizæ Co., Infusion of Beet Root, Rhus Tox., and many other substances and combinations are believed to exert a beneficial action upon the diseased membrane when administered by the mouth, but except for their laxative effects their action is doubtful or at the best uncertain, and reliance must be placed upon local remedies.

For the action of Aloes on hæmorrhoids see page 168.

Local treatment of hæmorrhoids.—This will vary with their exact situation, and with the stage of the affection in which they may chance to fall under the care of the attendant.

Inflamed piles, whether external or internal, are generally very painful, and often are accompanied by intense suffering when strangulation or constriction has been caused by the grasp of the sphincter. This agonising pain is often best marked in cases where the pile is small and of comparatively recent formation. Sedatives, and not the knife, are indicated in such cases. Leeches to the margin of the anus, or near to the surface of the tumour, Ice externally, or slipped inside the sphincter, or injections of iced water, may relieve pain and subdue congestion and throbbing. Fomentations or hot poultices, smeared with Belladonna or Opium Extracts, are often more soothing than cold, and what affords relief at one stage may be aggravating 12 or 24 hours afterwards, and the physician must ring the changes between cold and heat dryness and moisture. It will be necessary in such cases to effectually relieve the colon at once, and this is best done by copious warm water enemata, which may be repeated from day to day. Rest in bed in the horizontal position, or better still, with the pelvis elevated as high as may be consistent with comfort, is an essential element in the treatment. Local anodynes are most unsatisfactory in their effects upon congested, inflamed, or painful piles. Remedies of this class very often aggravate the distress. Cocaine, pastes, ointments or lotions of Belladonna, Opium, Morphia, Chloral, Chloroform, Aconite, Tobacco, Hamamelis, Hyoscyamus, Carbolic Acid, Creosote, and Iodoform, are often useless as pain relievers.

Morphia in the form of suppository ($\frac{1}{2}$ grain) will after some time give ease but not till it affects the cerebrum; in fact, it does not act as a local sedative in these cases. The pain is caused by the increased tension, and is not caused by the irritation or hyperæsthesia of excoriated nerve endings as in fissure or ulcer of the anus. Hence, local depletion, hot fomentations, warm injections or poultices, or iced injections or compresses are to be relied upon.

As a local rectal anodyne, when the tension has subsided, there is no remedy hitherto used equal to Conium. The preparation introduced by the writer (see page 53) is the only good method of using the drug in the form of an ointment. It may be pushed up the anus or freely smeared over the tumour, or applied upon the poultices. Its use is not followed by the speedy relief which it causes in fissure or pruritus, nevertheless it will give better results than the ordinary remedies used to relieve the pain of inflamed piles.

The Ointment of Galls and Opium is a favourite remedy in chronic cases, a little Cocaine, or Belladonna Extract, may be combined with it, but where a local anodyne and astringent effect is needed, here again the combination of the Conium Ointment with Sulphate of Iron (10 to 20 grains to 1 oz.) is in every respect better. Kiewitzow speaks very highly of the use of Calomel

suppositories. He states that they promptly arrest bleeding, relieve pain, and reduce the size of the piles.

Inflamed piles should not be cauterised, excised, or ligatured. If a thrombus form, a longitudinal incision should be made with the lancet and the clot turned out. If suppuration occurs a free incision with an abscess knife will give speedy relief.

Sloughing piles are best treated by poultices. The inflammatory, or sloughing process, may end in the removal of the trouble, and may effect a permanent cure.

In piles of long standing associated with periodical prolapse, slight hæmorrhage, or mucous discharge, the habitual use of cold water injections (5-10 oz.), absolute cleanliness, and frequent sponging with cold water, with the application of the Conium and Iron Ointment after each motion, often suffice to effect a cure.

Brunton advises a small plug of sheep's wool soaked in Hamamelis to be pushed up the bowel; after which a larger plug similarly soaked should be applied to the anus, a few of its fibres being pushed into the sphincter; this soon forms a felted pad, which acts as a support to the prolapsing piles, as well as a medium for the application of the drug, which, he states, has an extraordinary effect in stopping the hæmorrhage.

In more obstinate cases, astringent injections, as Tannic Acid (20 grs., water 3 oz.), Sulphate of Iron (10 grs., water 3 oz.), Tincture of Iron (1 drachm, water 3 oz.), Hamamelis (4 drachms, water 3 oz.), Alum (40 grs. to 3 oz. water), Hydrastis, Tincture 4 drachms, water 3 oz.), may be thrown up and retained as long as possible. Sometimes excellent results may be obtained by injecting 1 oz. Hazeline undiluted.

Suppositories of the same substances may be used with advantage.

Ointments are also useful, the best being Persulphate of Iron (30 grs. to 1 oz. Lard). Hazeline Ointment with 1 per cent. Cocaine, introduced by means of Allingham's depositor, gives decided relief. Dilute Citrine Ointment is also a good application in chronic cases accompanied with mucous discharge, it may also be used as a suppository. Lead Acetate may be employed in the same way. The latter applications generally cause much pain and smarting.

Nitric Acid, or the Acid Solution of Pernitrate of Mercury, applied to internal prolapsing hæmorrhoids, often gives satisfactory results. The speculum being introduced, and the surface of the pile wiped dry, the strongest acid is freely applied by a piece of wood or a glass brush, the skin being very carefully guarded, and the cauterised surface smeared over with chalk and oil afterwards. As a rule there is not much pain if the patient keeps to bed for some hours, and excellent results often follow.

Cauterising the surface of the pile with a hot iron or electro-cautery in a linear manner acts in the same way. Both remedies leave an eschar, which sometimes is rapidly followed by shrivelling

and disappearance of the enlarged vessels, and both are valuable methods of radical cure where the ordinary operations are contra-indicated, especially in cases where the tumour is small and sessile.

The injection of strong Carbolic Acid into external or internal hæmorrhoids is not free from serious danger, and should not be performed. Edwards reports brilliant successes in 38 cases by injecting 2 to 5 minims of carbolic acid solution (1 in 10 of glycerin and water), with an ordinary hypodermic needle, into the centre of each pile, and returning it immediately within the sphincter. The results are most satisfactory, no trouble ever resulting, and the patient is rapidly cured without lying up a single day. Other observers speak much less enthusiastically about the results of this method.

Unna's plan of treating piles by Chrysarobin has been modified by Kosobudski, who uses an ointment of Chrysarobin, 8 parts; Iodoform, 3 parts; Extract of Belladonna, 6; and Vaseline, 150 parts. For internal piles he uses suppositories, which, he claims, cure in three or four days. The following is their composition:—

- R. *Chrysarobini* gr. i.
 Iodoformi gr. $\frac{1}{2}$.
 Ext. Belladonnæ gr. $\frac{1}{2}$.
 Ol. Theobromatis gr. xxx.
 Glycerini q.s. misce.

Fiat suppositorium.

The ordinary surgical methods of removing piles are by scissors, the knife, galvano-cautery, or ligature, or by clamping, cutting, and the actual cautery combined, or by crushing and excision combined.

External piles may be removed by the use of scissors curved on the flat. As a rule, the hæmorrhage is trivial.

Cocaine (5 per cent. solution), injected hypodermically into the base of the pile, carbolic lotion (1 to 30), or the ether spray will generally produce sufficient blunting of the cutaneous sensibility.

McCarthy points out the danger of removing too much skin if the pile be situated close to the margin of the anus, as troublesome stricture of the orifice may result. This is unlikely. By catching up the folds of skin containing the pile with forceps, the scissors or knife should snip them off in lines radiating towards the anal aperture. The bleeding may be checked by the application of ice, or by the pressure of a pad of lint, held in position with a T-bandage.

Internal piles may be removed by ligature. Chloroform may or may not be used. Cocaine, 2-5 per cent, or Eucaine, 5 per cent., may be injected around the margin of the anus, and into the base

of each pile about to be removed. The operation in this way is rendered practically painless. If it is intended to dilate the sphincter, the injection should also be made at several points into the substance of that muscle. The operation is not necessarily a very painful one. The bowel should be well emptied by a large dose of castor oil the night before the operation, and a copious warm water injection should be given immediately before operating. If the patient possesses sufficient fortitude to undergo the operation without chloroform, he can readily bring the hæmorrhoidal mass into view by straining after the action of the enema. Should chloroform or ether be administered, this can be readily accomplished by an assistant, who everts the mucous membrane.

The patient lying upon his left side, with the legs well drawn up, an assistant separates the buttocks, and when the piles are well protruded, the surgeon seizes each with a toothed pile-forceps, and pulls very gently upon it, whilst he snips through the mucous membrane at its base with a pair of blunt-pointed scissors, leaving a groove round the insertion of the tumour close to the intestinal surface. Some surgeons prefer to make this groove with a tenotomy knife. As the forceps are held by an assistant, who pulls gently upon the pile, the surgeon passes a stout waxed silk or hemp ligature round its base, taking care to include the entire mass, and allowing the ligature to sink into the groove as it is tied as tightly as possible.

Each pile, when there are several, is treated in the same way, the ends of the ligatures cut off, and the entire mass, with the short ends of the ligatures, should be returned within the sphincter.

Where the pile is large and its base broad, after snipping through the mucous membrane at its base, the surgeon should transfix it with a curved needle armed with a double ligature. After cutting its loop, each half should be tied separately. Some surgeons remove a portion of the strangulated pile before finally tightening the ligature. Erichsen advises cutting the pile after ligature, applying Chloride of Zinc solution (1 in 8) and then rubbing into the stump Iodoform in crystals.

It is advisable to remove any external piles by scissors at the same time, taking care not to include them or any "intermediate" ones in the ligatures whilst tying the internal ones.

After the operation the patient should remain in bed and have a $\frac{1}{2}$ grain Morphia suppository, or a suppository of Conium. Ice may be applied locally, though it is seldom required, and hot fomentations may be grateful.

The bowels should be permitted to rest for three days at least, Castor Oil, Cascara, or a large Olive Oil or warm water enema being required to start them after all pain, throbbing, hæmorrhage, retention of urine, tenesmus, or other troubles are relieved.

The ligatures should be allowed to come away, without any

interference, as the bowels act. They often come away about the fifth or sixth day, but may be delayed till the twelfth.

[Many modern surgeons advocate excision and suture, with a view to obtaining primary union. The following plan, which I have adopted for some time, will be found very satisfactory.—The mucous membrane is washed with ^{10%} Perchloride. The sphincter is dilated. One of the piles is caught in a pair of forceps and pulled well down. A long narrow-bladed forceps (Koehler's artery forceps answers admirably) is then applied to the base of the pile so as to include a vertical fold of mucous membrane 1-2 inches long. The pile having been pulled well into the grip of the forceps, their blades are clamped, and the projecting pile removed with scissors. A needle threaded with catgut is passed through the fold of mucous membrane just above the forceps, and the end of the catgut is firmly tied so as to include the artery running into the pile. The upper end being thus fixed, a continuous suture is applied loosely *around* the blades of the forceps. The blades are then removed, and the suture rapidly tightened and secured at the lower end. Each pile is treated similarly, and when the operation, which takes about 15-20 minutes, is completed, 4-6 vertical lines of suture remain within the rectum. The operation is bloodless. No attempt is made to ensure subsequent inaction of the bowels. The patient is up and about at the end of a week.—A. B. M.]

The operation by clamp and cautery is still preferred by many operators. After a thorough evacuation of the bowel by a purgative or a large tepid water enema, or by both agents, the patient is placed upon his back and brought completely under the influence of chloroform or ether. The lithotomy position with the crutch is the best where assistants are not numerous but some surgeons prefer the patient to lie upon his left side, with the thighs well flexed and the nates separated by an assistant. By introducing both thumbs into the anus and making steady traction the sphincter is readily dilated, the pile, seized with forceps, should be gently pulled down, and the clamp applied to its base. With a scalpel or bistoury the pile is excised, and the actual, galvanic, or Paquelin's cautery applied to the stump, so as to burn it down almost to the level of the clamp, which is then removed, any bleeding point being again touched by the cautery, and the patient treated afterwards as in the case of using the ligature.

Allingham and others operate by using a powerful screw-clamp, which is applied to the base of the pile and after applying strong pressure in a longitudinal direction for a couple of minutes, the projecting portion of the tumour beyond the crusher is excised and the instrument removed. No hæmorrhage whatever need occur and speedy and comparatively painless recovery ensues.

Whitehead's operation of excision of the entire pile area is not likely to become universal when the ligature, and clamp and cautery continue to give such satisfactory results. Mathews

reported in 1888 that he had used the ligature in 1,000 cases without a single recurrence of the disease and without a death, and about the same time Whitehead stated he had excised the entire mucous membrane of the lower end of the bowel 300 times with similar results.

HÆMOTHORAX.

When this is caused by some blood condition, as in purpura, cancer, tubercle, &c., the treatment of the primary cause is of first importance. In such cases probably only a blood-stained serous fluid exists, and the management of the case will be best carried out upon the lines indicated for pleural effusion.

Where active bleeding is occurring into the cavity of the pleura without any external wound, the case may be considered, in the majority of instances, as beyond the reach of art. Nevertheless there are certain measures which may afford some hope. The patient should be placed in bed, and have ice freely applied to the affected side; he should lie upon this side unless where this interferes with the repeated applications of the ice. Food should only be given in quantities just capable of maintaining life, and the utmost quiet and freedom from excitement must be maintained.

Opium should be given in moderate doses, and of all the internal hæmostaties, there are only two worth trying in such cases and these are the Chloride of Calcium in 20 gr doses every two or three hours, or the Suprarenal substance, 10-15 grs.; it may be given hypodermically in doses of 2 grs. Rapid purgation by a concentrated solution of Magnesia Sulphate, as recommended by Professor Hay in dropsy, may be tried. The old heroic method of bleeding freely from the arm may, by rapidly making an impression upon the circulation, check internal hæmorrhage. (See under Hæmoptysis, page 359.)

Where the blood has been already poured out in quantity sufficient to compress the lung and cause serious embarrassment to the breathing, a trochar and canula may be employed to draw off the fluid blood or the serum of coagulated blood. If a wound exist it may be enlarged, and a fair sized drainage tube may be inserted into the pleural cavity.

Should the hæmorrhage be coming from a wounded intercostal or internal mammary artery, this must, if possible, be stopped by ligaturing both ends of the divided vessel after enlarging the wound. In order to accomplish this it may be necessary to remove a portion of the rib or its costal cartilage.

Plugging of the wound may be performed in such a way as to ensure that the hæmorrhage be not simply made to flow on internally after the aperture is closed externally. This can be done by laying a piece of lint upon the wound, and pushing it in with a finger tip so as to make a little bag or pocket which can be

filled with iodoform gauze, and the whole covered by a large pad of gauze secured by plaster.

HANGING—See *Asphyxia*.

HARE LIP.

The first question to be decided in the treatment of this unsightly deformity is, "*When to operate?*" The answer will depend upon many considerations. Chief of these will be the ability of the infant to take nourishment. Should the cleft in the lip prevent the successful use of the mother's nipple the operation may be performed within the first week or ten days with advantage.

As a rule, in this country the operation is deferred too long, the infant suffering in health from the difficulties of obtaining nourishment, so that when presented for operation it is not in a favourable condition. The first duty of the physician in all cases is to see to the nutrition, and if sucking is impossible or difficult, the infant should be fed from a spoon with the milk drawn from its mother's breast till sufficiently strong to stand the shock of a cutting operation and its consequent hæmorrhage. When there is no difficulty in sucking, the sixth to the twelfth week is a favourable time for remedying the deformity. Where there is a projection of the intermaxillary bone and cleft palate, the end of the fourth to the end of the sixth month will be early enough to think of operating.

A towel being wound round the infant so as to fix its arms close to the body, chloroform is administered as the little patient lies upon his back on a table or upon the lap of a steady nurse, with his head resting upon the knees of the surgeon. The lip must be thoroughly separated from its bony attachments by cutting and gently tearing through the reflected mucous membrane in the neighbourhood of the cleft and beyond it, before any attempt is made at paring the edges of the cleft. After the soft parts are found to glide freely over the alveoli a fine, sharp scalpel is used to pare off and completely detach the edge of one side of the cleft till the red margin of the lip is reached, when the incision is prolonged clean through the blunt angle and for a short distance along the free margin of the lip by turning the cutting edge of the blade outwards. The remaining edge of the cleft is similarly pared till the lower angle of the cleft is reached, when the knife is again turned outwards to continue the incision along the red margin of the lip without detaching the dissected paring, which is then stitched to the opposite blunt angle so as to fill in the notch which would otherwise be left in the free margin of the lip.

The margins of the cleft are then brought together by silkworm gut sutures and the flap of mucous membrane fixed in position by the finest silk, such as is used by oculists. The wound is sealed with a mixture of Tr. Benz. Co. and Collodion, equal parts.

The sutures are removed on the third or fourth day.

Bird's method of operating by the rectangular flap ensures the minimum of deformity, especially in those cases where there is a marked want of symmetrical form between the sides of the cleft.

In double hare-lip the margins of the clefts are to be treated in the same way, and, if there be no bone displacement, the operation on both sides being carried out at the one sitting the case presents no difficulty.

Where the intermaxillary bones project, they must, if possible, be preserved by twisting them into their proper place or by severing partially their posterior attachments and forcing them back with strong forceps into the gap in the anterior part of the hard palate. Their destruction means the loss of the central and perhaps of the lateral incisors. After repeated failures in obtaining union, paring of the edges of the cleft may again and again be tried with some prospects of success at a later age.

HAY FEVER.

The great majority of cases, as clearly pointed out by Bronner, may be divided into two well-marked classes, *i. e.*, those in which the mucous lining of the nasal passages, perfectly normal at all other times, swells, becomes congested, secretes freely, and is associated with sneezing and coryza.

The second group of these includes those where the signs of chronic hypertrophic rhinitis are always present, as evidenced by a thickening of the mucous membrane covering the lower and sometimes the upper turbinated bones, the septum, and nasal floor.

This latter group is the more common, and, when the hay season comes on, furnishes a large number of the cases of so-called hay asthma or hay fever. The first class of cases, though amenable, to a certain extent, to purely local treatment, are neurotic in their origin and require constitutional remedies. The second class must be boldly met by local agents, and it is in dealing with them that the most satisfactory and lasting results have been obtained. There is little use in the application of sedative or caustic solutions for the removal of the chronic rhinitis, by far the best measure is Cocaine and the Galvano-cautery.

The object is to so cauterise the erectile tissue as to form an adherent cicatrix which will permanently bind down the mucosa to the periosteum, and at the same time, ensure the complete destruction of the hypersensitive areas existing in the nasal membrane. By a 15 per cent. Cocaine Solution the thickened mucous lining is rendered insensible, after which, with a fine blade or platinum point, a deep groove is burned with the galvanocautery along the entire length of the inferior turbinated bone.

There is a very far prospect that the removal of the hypertrophic rhinitis will prevent, or very materially modify, the paroxysmal sneezing and coryza produced by the inhalation of pollen and dust.

The treatment of those cases of true or neurotic hay fever in which no structural alteration is apparent in the nasal membrane, except at the time of the attack, is much less satisfactory. In such cases remedial measures must be directed (1) to the neurotic state (2) to the local hyperæsthetic condition, and (3) to the prevention of the access of the irritant.

The first indication is best carried out by the use of every means whereby the highest standard of health can be maintained in the intervals between the attacks. Many authorities regard hay fever as a pure form of asthma, and recommend the treatment indicated in asthma, and Goodhart states that Arsenic will relieve all the symptoms. Tonics, like Zinc Sulphate or Valerianate, Iron, Bromides, Quinine, Strychnine Iodides, shower baths or sea bathing, are certainly worth trial during the months preceding June, whilst the attack is on they may be worse than useless. The indication for each remedy will be found by studying the peculiarities of each case.

Coupled with such preliminary treatment directions should be given to the patient whereby he may attempt to avoid the irritating cause of the seizures. Any locality where the pollen of grasses and other plants exists in abundance should, as far as possible, be avoided. City in-door life, a sea voyage or residence in a high altitude, or a sojourn at a sea-side spot, destitute of much vegetation, may enable the victim of hay fever to stave off the attacks. Respirators, goggles, veils and plugs of cotton wool in the nostrils may in some cases mitigate the amount of coryza and sneezing by preventing the admission of the pollen grains, but, as a rule, their use causes acute discomfort, and, as preventive remedies, they are generally unsuccessful.

Treatment directed to allaying the local irritation is of more importance than constitutional or tonic remedies.

Antipyrine in full doses (15 grains) in some cases possesses the power of cutting short the attack. Should it fail after a few trials it may safely be abandoned.

Recently Suprarenal Extract, given in 5 gr. tabloids, allowed to slowly dissolve in the mouth every two hours, has been found most beneficial in cutting short the attack. Its action is probably local upon the engorged nasal tract, as it acts best when applied directly to the nasal mucous membrane.

Morphia, Aconite, Pilocarpine, Lobelia, Muscarine, Caffeine, Salicylic Acid, Veratrum Viride, Grindelia, Atropine, Hazeline, Bromides in full doses, Quebracho and many other powerful drugs have been administered with very indifferent successes, and with the exception of the occasional usefulness of Antipyrine or Antifebrin remedies given by the mouth, are generally most unsatisfactory and the physician has to place his reliance upon local treatment.

Of all the innumerable local remedies there is none to equal in rapidity and certainty the free use of the galvanic-cautery.

After local anæsthesia the sensitive areas on the nasal membrane should be destroyed, and an adherent cicatrix produced over the surface of the inferior turbinated bone, with a view of preventing erection of the mucous membrane, as already described upon page 375. In proportion to the thoroughness with which the operation is carried out will the success be, and sometimes the cauterization must be repeated several times.

Next in value and less formidable, at first sight, is a method of treatment introduced by Sir Andrew Clarke. In the writer's hands it has given much satisfaction, one case yielding completely to its use. The interior of the nose and the pharynx (through the nostrils) are freely swabbed out with the following solution:—

R. *Glycerini Acidi Carbolici* ʒij.
 Quinnæ Hydrochloratis ʒn.
 Hydrargyri Perchloridi gr. i. *misce.*

Fiat solutio cum calore.

Its application is followed by pain and smarting and considerable aggravation of the local irritation. This, however, speedily subsides.

Müller, of Vienna, paints the nasal cavities with Nitrate of Silver solution (10 grs. to the oz.), irrigates with several pints of water, and then applies Menthol, 45 grs., Resorcin, 45 grs., dissolved in 4 oz. Alcohol. Two drachms of this solution diluted with water are applied every 4 hours.

W. Williams reports highly of a nasal spray, after failure of most of the above, consisting of a 1 in 1,000 solution of the Iodide of Mercury.

A 10 per cent solution of Cocaine almost immediately reduces simple erection of the mucosa and relieves nasal obstruction, but, as pointed out by Hall the secondary effect of the drug is to cause dilatation of the vessels which finally leads to increase in the thickness of the membrane and aggravation of the disease.

Tabloids, containing $\frac{1}{4}$ grain, may be gently pushed up into the nostril as far as they can be carried by the tip of the little finger, and, as a rule, speedy temporary relief may be thus easily purchased.

A spray may be employed when time is not an important factor, but the tabloids can be carried about by the patient and used at a moment's notice. Antipyrine solution (15 grains to 1 oz. water) may be used as a spray, and is not open to the serious objections that maintain against the habitual use of cocaine. Its effects are not, however, so prompt or pronounced.

H. C. Wood recommends bougies of cacao butter containing each 1 gr. Cocaine and $\frac{1}{16}$ gr. Atropine, thrust in between the septum and the swollen turbinated bones whilst the patient is lying down.

Menthol rubbed over the sensitive areas is also in some cases efficacious in checking or modifying the attack. Hull uses a 10-20 per cent. solution in oil, brushed or sprayed over the sensitive regions.

Nitrate of Silver (5 to 15 grs. to 1 oz.) may be used with a brush. Terebene, Creosote, Pinol, Bromine, Iodine, Camphor, Carbolic Acid, or Oil of Peppermint or Eucalyptus, mixed with hot water and used as an inhalation, has been often productive of benefit in allaying irritation, relieving sneezing, and checking coryza.

Chloroform has been resorted to with advantage—the vapour of a few drops inhaled from the handkerchief or the palm.

Strong Acetic Acid or Ammonia inhaled from a bottle is a harmless and convenient remedy, and is sometimes beneficial; and strong Linctus of Iodine may be used in the same manner.

The usual asthma remedies, burning of Nitre papers or cigarettes, or smoking Stramonium, Datura Tatula, Lobelia, or Tobacco may be tried.

The nasal douche is of much value in some cases, and by its means Corrosive Sublimate (1 gr. in 5 oz.), Boroglyceride (30 grs. to 1 oz.), Quinine (1 gr. to 1 oz.), Iodide of Potassium (4 grs. to 1 oz.), Iodine (½ gr. to 5 oz.), Aconite (10 minims of the tincture to 1 oz.), Hazehine (1 drachm to 2 oz.), Sulphurous Acid (2 drachms to 5 oz.), Carbolic Acid (1 drachm to 10 oz.), Tannin (3 grs. to 1 oz.) may be applied to the nasal membrane and back of the pharynx.

The various snuffs consisting of Bismuth, Sugar, Morphia, Gum, &c., are worse than useless.

HEADACHE.

As headache is but a symptom of a large number of widely different affections, its treatment cannot in a work like the present be discussed satisfactorily under this heading. Where headache is a prominent symptom of any disorder its management will be fully referred to under the name of the disorder. (See Meningitis, Megrin, Typhus and Typhoid Fevers, Amenorrhœa, Bright's Disease, &c.)

The only rational treatment of headache must consist in an attempt to remove its cause when this is possible, and the most common cause which the physician meets with in practice is some altered or poisonous condition of the blood manifesting itself by its toxic influence upon the cerebral centres. The general rule in such cases should be to so act upon the eliminatory organs as to cause the excretion of the offending material from the system. The marked success following the purging, sweating, and diaphoretic remedies given to relieve the intense cephalalgia in uræmia is a striking proof of this; so also is the magical effect of active open-air exercise in giving relief to the headache caused by breathing impure air or an atmosphere impregnated with carbonic or other gases. The headache of fevers and inflammatory conditions,

though probably depending upon a similar cause, is not so easily dealt with, as the abnormal heat production and manufacture of the toxic agent progresses in spite of treatment. Nevertheless, considerable relief may be obtained in such cases by antipyretics and by smart counter-irritation to the back of the neck and occiput.

It is worthy of note how frequently a sinapism applied to this region relieves many different varieties of severe headache depending obviously upon different causes.

Congestive headache is speedily relieved by smart Purging, and hot foot-baths or counter-irritation applied to the lower extremities, and in severe cases Leeching, Cold Affusion, Ice, and Bromides.

Anæmic headache, upon the other hand, is amenable to Iron, Quinine, stimulants, and concentrated food, remedies which aggravate the foregoing condition. This class of case is sometimes greatly relieved by small doses of Nitroglycerin or Amyl Nitrite.

Headache depending upon ocular troubles and astigmatism, yields speedily to measures which correct these causes, and as this form of cephalalgia is much more common than is generally imagined, the careful examination of the eyes in obscure cases should not be overlooked. The writer has seen some cases of severe and chronic cephalalgia yield almost immediately to skillfully selected spectacles.

The reflex headache, depending upon stomach troubles and acute dyspepsia, subsides rapidly after evacuation of the gastric contents. Hence the great value of emetics in such cases. The Mineral Acids, Bicarbonates of Soda and Potash, and Nux Vomica often relieve cases belonging to this group. Oil of Eucalyptus, in doses of 5 minims, often relieves various forms of headache.

Uterine and menstrual derangements, as a cause of headache, are well recognised, and, as a rule, the head pain rapidly subsides upon the removal of the cause.

Gout or uric acid diathesis is sometimes associated with severe headache, and, notwithstanding the high praise given to full doses of Salicylate of Soda, the writer has found it often fail utterly. The White Mixture, in full cathartic doses, does better than anodynes.

Under Megrin will be fully enumerated the host of remedies used to relieve nervous and sick headaches, and though the mysterious and striking powers of Antipyrine and Antifebrin are best demonstrated in severe migraine, nevertheless it must be remarked that in many cases not migrainous these remedies relieve pain in a remarkable manner, and as routine agents for the relief of headache they are much more valuable than Bromides and Caffeine.

Electricity has been tried with varying success in several varieties of headache. The writer has obtained good results from a weak continuous current of 4 Léclanché cells where other

measures failed. Large doses of Iodide of Potassium have the same peculiar property of relieving deep-seated, obstinate cephalalgia, and in the headache depending upon cerebral tumours, it should always be steadily administered, and the dose may be increased till 30 grains are reached. Alternating with the doses of this drug, full quantities of Antipyrine may be given, in conjunction with a series of small blisters upon the scalp, and counter-irritation to the nape of the neck.

The headache caused by inflammation of the frontal sinus is treated by Seiss with pledgets of cotton wool soaked in a 5 per cent. Solution of Cocaine, after which any mild antiseptic spray is used, and when all discharge is washed away, he insufflates the nostrils with a powder consisting of 6 grs. Morphia, 1 gr. Atropine, 2½ drs. Bismuth, and 1½ drs. Acacia.

Vansant recommends the forcible flushing of the nasal accessory sinuses with a stream of hot, dry air for all cases of frontal headache.

HEAD INJURIES.

The uncertainty of diagnosis renders the treatment of these affections more than ordinarily difficult and embarrassing. Only a faint and imperfect outline of their management falls under the scope of the present volume. Considering that the most serious consequences may ultimately follow injuries which leave no visible external mark behind them, the surgeon will be wise who treats all head injuries as serious when first coming under his notice.

The key to the diagnosis and treatment of these accidents is to be found in a careful examination of the mechanical forces at work in the production of the injury. Only in this way can a fair estimate be made of the amount of damage sustained by the cerebral tissue and blood vessels, simple wounds in the scalp and fractures of the cranial bones possessing little importance, unless when associated with internal laceration or contusion.

Concussion symptoms, if present, are to be treated by absolute rest till reaction sets in (see Concussion, page 157, and Collapse, page 156), warmth to the surface by hot-water bottles and warm flannels, and in cases of severe concussion and collapse rectal injections of warm milk. Counter-irritation to the extremities in a mild form may be tried, but alcoholic or other stimulants must be avoided, or only given in most exceptional instances.

The great difficulty in dealing with these cases is to avoid falling into the error of doing too much. Where reaction is slow of appearing, there is probably some serious damage to the brain, and if the attendant cannot restrain himself and assume a position of masterly inactivity, his interference, prompted by a feeling that he must do something, will probably result in hastening a violent reaction, which may end in further hæmorrhage or encephalitis.

The surgeon must never neglect to inquire as to retention of

urine, which is a common complication in these cases, and must be relieved by the passage of a soft rubber catheter.

When the rallying stage has ended in reaction, rest and absolute quiet should be maintained. One smart purge—5 grs. of Calomel or half a minim of Croton Oil—may be given. Where these are contra-indicated, a copious warm water enema may be substituted. The patient should lie in a darkened room upon his back, with the head elevated, and the hair removed, with ice or Leiter's tubes applied to the scalp in severe cases.

Leeching, wet cupping, or venesection may be demanded in plethoric subjects with much mental excitement. Alcohol, opium, and animal food are to be forbidden, the diet consisting entirely of milk, diluent drinks, and harmless slops. The use of even beef-tea is sometimes followed by an increase of headache and a rise of temperature, and a pure vegetarian diet should be insisted upon for a considerable time after the symptoms have subsided. As the symptoms of reaction and the excitement subside, the maintenance of rest and quiet for 10 to 20 days generally leaves the patient well unless serious cerebral damage has occurred.

In those cases where the original injury was caused by a bad fall, or by the blow of a large, heavy object, the general confusion of the brain which results may end in fatal collapse.

It is not often that surgical measures are indicated in this class of case, as the diffused injury to the brain, if not relieved by the above treatment, will not be at all likely to yield to operative interference. Should, however, the symptoms of encephalitis follow reaction and end in signs of cerebral abscess, and if the pus can be localised, Trephining may be determined upon with some prospect of success. Such a procedure is only to be undertaken in this class of case after the gravest deliberation and analysis of symptoms. Local brain symptoms in cases of general shaking or severe brain confusion may be present merely as part of the general brain injury, which of itself will be sufficient to produce a fatal issue, even after the local trouble has been successfully dealt with.

Bryant advises local interference only in local injuries but recent results prove that the inflammatory effusion and abscess following general cerebral confusion or laceration may be dealt with successfully by trephining.

In those cases where the injury is localised, as in blows and wounds produced by sharp instruments, or by any force acting upon a circumscribed area of the skull, and causing fracture of the cranial bones, with or without depression and associated with local brain symptoms, the line of action is clear. Depressed bone should be elevated without delay. Blood effused underneath the site of injury, and causing compression symptoms, should be removed by trephining.

Authorities differ regarding the wisdom of elevating depressed bone when there are no symptoms of compression. Recent

experience points strongly to the advisability of not waiting for signs of compression or irritation. Considering the cases in which the physician finds symptoms of local convulsions following long after circumscribed cranial injuries, there should be no hesitation in following Macewen's advice.

He states that when there is marked depression of the skull, involving both tables, it ought to be elevated without waiting for the development of symptoms of compression or of irritation, provided the surgeon has the means of preserving the wound in an aseptic condition.

The use of the trephine in fractures of the base of the skull has not been much practised. Warren has given some instructive cases where trephining was successfully performed with the view of affording drainage, the cribriform plate being drilled for this purpose. He recommends trephining above the external auditory meatus in fractures of the temporal and sphenoid bones and those involving the anterior fossa, and he selects the occiput below the superior curved line, with the view of draining the posterior fossa.

In a fracture involving the vault of the pharynx, he recommends trephining a little anterior to the auriculo-bregmatic line, and the insertion of a drain of antiseptic gauze along the floor of the skull in the route of the fissured bone.

In fractures of the base, it is of vital importance that the avenues through which septic matters may be introduced should be guarded; thus irrigation and insufflation of the nostrils, ears, pharynx, and Eustachian tubes should be carefully attended to by means of sprays of weak Corrosive Sublimate (1 in 1000) or of Carbolic Acid (1 in 100), and the packing of the ears and nose with Iodoform or other antiseptic gauze.

HEARTBURN—See Dyspepsia.

HEART—Dilatation of.

This may be a sequel to valvular lesions, and, indeed, is often the condition which compels the subject of valvular disease to seek the advice of the physician. Under these conditions the treatment for failing compensation—*i.e.* cardiac tonics and rest, with attention to the bowels, kidneys, skin, and liver, will meet all the requirements of the case. The condition may supervene after exercise following recovery from serious illness, and it is often a sequel of influenza, and the importance of absolute rest in these cases cannot be exaggerated.

Similar treatment will maintain in those cases where the dilatation has been brought on by severe prolonged muscular exercise or heavy mental or emotional strain. Broadbent points out the necessity of relieving the ventricles of work, and giving them strength whilst at the same time measures are employed with a view of depleting the venous engorgement.

Rest and cardiac tonics fulfil the first indications, whilst mercurial and saline purgatives accomplish the second. Often cardiac tonics fail in giving relief till the balance of the circulation is restored by draining the portal system. The after-treatment will then practically resolve itself into the judicious exhibition of the various agents indicated in cases of advanced valvular disease associated with failing compensation. The hypodermic injection of Strychnine is invaluable at the beginning of the treatment, and may save life in acute cases. The writer's best results in such cases have been achieved by absolute repose in bed, with mild salines and the following:—

R. *Liq. Strychninae Hyd.* ℥i.
 Sodu Iodidi ℥iii.
 Tinct. Strophanthi ℥ij.
 Glycerini et Aquæ ad ℥iv. misce.
℥l. mist. Cpt. ℥j. ex aqua quater in die.

HEART—Functional Affections of.

Where no organic cause for cardiac disturbance exists, embarrassed respiration, palpitation, pain, and irregularity of action may demand prompt treatment. One or all of these symptoms may be present, and the treatment should be directed to the relief of the paroxysmal attack in the first instance, and secondly to its prevention during the intervals, and thirdly to the continuous treatment of the case in those subjects where the symptoms are more or less constantly present.

Under Goutre, Exophthalmic, and under Angina Pectoris, the managements of these affections are described.

Attacks of severe functional disorder should, if possible, be referred to their source before effective treatment can be directed against them. Thus, an overloaded stomach, or an attack of acute dyspepsia, may produce alarming cardiac symptoms, which may be best treated by prompt evacuation of the gastric contents. Any rapid accumulation of gas or fluid in the abdomen may cause such displacement of the diaphragm as may lead to serious cardiac embarrassment, and when possible the cause should be remedied at once.

In attacks depending upon intrinsic causes, as altered innervation, &c. the best remedies will be stimulants like Ammonia, Ether, Brandy, and in hysterical females, Asafetida, Valerian, Musk or Sumbul, while the paroxysm is severe.

Ice or cold applied to the cardiac region sometimes gives relief, but where there is marked irregularity or intermittent action this is not a safe practice. The same remarks apply to galvanism and Parodisation of the vagus in the neck.

A little Ether, inhaled from a sponge or inhaler, is safer than Chloroform, and where there is increased arterial tension nothing gives such marked relief as a Nitrite of Amyl capsule or a Nitroglycerin tabloid.

Allbutt recommends the hypodermic injection of Morphia to cut short the neurosial paroxysm of dyspnoea or restlessness, to restore the order of rhythm, and to thus pacify the organ rocking under the tumult of its unbalanced parts and to prevent the heart from being tripped up by the intrusion of a neurosis.

Ammonia or strong Acetic Acid, or even strong snuff to the nostrils, sometimes gives speedy relief.

Veratrum Viride and Aconite are recommended, but they may do mischief unless there be marked hypertrophy present.

Digitalis is generally useless when given to relieve a paroxysm, and Bromide of Potassium is also quite too slow in its action. Chloral Hydrate is of much value, but should not be given if there be a reasonable suspicion of organic disease, and if administered at all should be given with a moderate dose of whiskey.

Warm carminatives, like the strong Tincture of Ginger, may be added to the Ammonia or Ether with advantage and a cordial like the following will generally prove speedy and efficacious:—

R.	Spt. Ammon. Aromat.	℥i.
	Æther. Sulphuric.	℥ii.
	Tinct. Zingiber. Fort.	℥iii.
	Ol. Mentha Piper.	℥i.
	Spt. Camphoræ	℥iiss.
	Tinct. Card. Co. &c.	℥iii. misc.

Fit. mistura. Signa—"Take a small tea-spoonful in a wine-glassful of water every 15 minutes whilst the palpitation and difficulty of breathing are severe."

A firm, decided expression of opinion upon the safety of the patient's prospects of relief, often acts like magic in those cases where the attack originates in or is aggravated by mental or emotional causes. Balfour lays stress upon the importance of noticing the effect of exertion, if this does not increase the palpitation and uneasiness, the case may safely be regarded as functional, and when the physician is certain that the patient's heart is not the seat of organic disease this clear statement has a very decided effect upon reducing the frequency and severity of the attacks.

In the intervals between the attacks everything tending to depress the nervous system must be avoided, late hours especially, with excess in the use of tea, tobacco, and alcohol and sexual excitement should be given up. Regularity in meals and in taking open-air exercise is of importance, as is also the avoidance of anything like brain over-work or high business pressure. This latter is of great importance, as functional disturbance may ultimately end in organic lesion if these causes be continued.

Every departure from the highest standard of health must be sedulously attended to—anæmia met by Iron and Arsenic; plethora by exercise, Saline purgatives, and corrected dietary; dyspepsia by appropriate remedies, sleeplessness by Paraldehyde; uterine ailments by local and general medication. Where the paroxysms have been caused by prolonged muscular exercise or overwork, absolute rest is imperative. Of drugs there are several which have been highly recommended for administration during the intervals between the attacks, after the correction of any disordered condition which may have been present.

Digitalis is the most potent of these, and its administration has been recommended upon high authority as a remedy for palpitation of a purely neurotic character. The writer has not only seen it fail in many cases, but he has found it to aggravate the condition sometimes. Unfortunately there are no means by which its value can be decided in a given case till it is tried, its effects should be closely watched, and its administration stopped after 2 weeks trial if not satisfactory. The dose should not exceed 5 minims of the tincture.

Bromide of Potassium, in some instances, prevents attacks, but the writer's experience of its use leads him to believe that it should not be given for long periods without intermissions, and in these Digitalis can be sometimes given with advantage.

Belladonna in minute doses, and Strchnine in small doses, have occasionally given good results, and Iodide of Potassium, 5 grains 3 times daily after meals, often affords the best results after failure of everything else. Antipyrine (5 grs.) may relieve where the before-mentioned drugs have failed.

The writer has obtained much more uniformly successful results from Easton's Syrup, in drachm doses, than from any other remedy except the Iodides, and he believes it to be the best routine treatment in simple or neurotic palpitation. Should there be any obscure organic lesion present, it cannot do harm, and it is likely to do good. His plan is to give it for one month, and then to add 5 minims of the Tincture of Strophanthus to each dose whilst the treatment is continued for another month, after which the plain syrup is to be continued. The following mixture may be given:—

R *Acidi Hydrobrom. Dil.* ʒvj.
 Tinct. Belladonnæ ʒiii.
 Tinct. Nuc. Vomica ʒii.
 Glycerini Purificat. ʒiss.
 Tinct. Quininae ad ʒvi. *misce.*

Fiat mistura. Capiat cochlearium medium ex ʒj aquæ ter in die ante cibos.

Barium Chloride may be given where cardiac pain is marked. The dose should not exceed $\frac{1}{2}$ grain in pill or solution every 8 hours.

The irritable heart of young subjects, often produced by irregularity in exercise, such as cycling at high speed after months of abstinence from all exercise, yields to rest and graduated or systematic exercise; the irritable heart of old subjects must be treated generally as a more serious affection, whose main character is a fatty degeneration or dilatation rendered evident by temporary strain or emotion.

In those cases characterised by great frequency in the action of the heart, and known as instances of the "Rapid Heart," or Tachycardia, the above agents may be tried often with benefit, but Sansom has shown that, in the really severe cases, drug treatment produces no effect. He particularly recommends the application of the continuous current over the region of the great nerve centres. The writer has obtained good results from a current of 5 Léclanché elements, with one pole over the sterno-mastoid, and the other over the heart, for 15 minutes twice daily. Allbutt advises a tight abdominal binder.

Da Costa, under the term *Cardiac Asthenia*, includes those cases of functional affection in which there is habitual weak action of the heart, due to nervous failure or weakness of muscle, generally following excessive brain work or worry. The pulse is frequent, but not irregular, and the first sound resembles the second in character. He begins the treatment by rest in bed, followed by graduated Shower-baths, Massage, and Swedish movements. He places most reliance in Strychnine, next in Arsenic, and then in cardiac tonics.

HEART—Fatty Degeneration of.

Excluding those cases where this condition supervenes upon typhus, typhoid, or other fever, or wasting diseases, or phosphorus poisoning, where speedy recovery follows the removal of the cause, and the administration of Iron, stimulants, rest, and concentrated food, there remain those examples of the disease coming on for the most part in advanced life.

Fatty degeneration appearing as the last scene in the progress of valvular lesions falls under the treatment suitable to those affections. Only the management of the disease occurring as a true senile degeneration, or resulting from disease of the coronary arteries, need be here narrated.

Being essentially an error of mal-nutrition the first indication should be to correct every error in living, and to prevent the slightest violation of any health law.

The diet should consist of wholesome concentrated food in moderate amounts administered at regular hours, long fasts and hearty meals, especially late and heavy dinners, being strictly forbidden. Well made strong beef-tea, being an excellent cardiac stimulant, may be given between meals with advantage. Alcoholic stimulants are to be used in the smallest quantities and are better avoided entirely except as medicinal agents at times of fainting or threatened collapse. Their use as beverages generally does harm, but in many cases a little light wine may be taken with advantage.

Tobacco is injurious. Regular hours are essential—"early to bed and early to rise" is a good rule. Purity of air breathed whilst asleep or awake is of importance. Where the patient's means and occupation admit of it, he should be advised to spend the most of his spare time in the open-air. Carriage exercise is to be recommended only when gentle walking causes fatigue. Climbing or very active work must be given up, rising ground and long flights of stairs are to be avoided, or only attempted with great deliberation.

Everything that worries or annoys, and indeed all forms of brain work liable to produce excitement or exhaustion, are to be cautioned against, and occupations or recreations conducive to quiet and contentment should be recommended. By these means life may be prolonged without drugs.

Remembering the danger of a fatal syncope supervening, rapidly diffusible stimulants like Ammonia (Sal Volatile), Whiskey, or Ether should be within the reach of friends or attendants, and should be administered in diluted form after the horizontal position is adopted. Nitrite of Amyl may be useful.

For these emergencies a mixture like the following is of use:—

R	<i>Spiritus Ætheris</i>	℥j.
	<i>Tr. Belladonnæ</i>	℥ii.
	<i>Spiritus Ammon.</i>	Ar ℥j.
	<i>Tinct. Zingiberis Fort</i>	℥vj. misc.

Fiat. mist. Coch. min. dyspnæa urgente ex cyatho aquæ, s.

Where cardiac collapse and breathlessness do not soon pass off a hypodermic of 1 to 2 minims of Liqueur Atropinæ may be

given, and free inhalations of Oxygen are highly recommended by Douglas Powell.

Of drugs intended to strengthen the muscular fibre many have been highly recommended for constant administration upon empirical or rational grounds. In cases of pure fatty degeneration of the heart uncomplicated by valvular lesion, hypertrophy or dilatation, the ordinary cardiac tonics—*Digitalis*, *Strophanthus*, *Sparteine*, *Convallaria*, &c., are often useless, and may do mischief unless when given in small doses and in combination with a vasodilator like *Nitroglycerin*.

Phosphorus and *Arsenic*—drugs which in large doses cause fatty degeneration of the heart—have been praised. The writer has never seen any decided benefit follow their use, and he has ceased to prescribe them. *Ergot* is of doubtful value, but *Iodides* are of very great use, especially in those cases associated with pain and cardiac distress.

Iron and *Strychnine*, if tolerated, are not open to any objection, and may be freely administered with a fair prospect of success. *Strychnine* is the best drug we possess for this affection. *Yeo* combines *Coca* with it. *Easton's* or *Fellow's Syrup* may be taken for long periods with advantage, and *Cod Liver Oil* may be given at the same time.

General Massage is indicated, and in the early stages a course of *Nauheim baths* is very beneficial. These are dangerous at a later stage. *Galvanism*, which has been recommended, is an agent which the wise physician may well hesitate to employ until we know more about its effects upon the healthy heart.

The condition of the skin, kidneys, bowels, and all the excretory organs is of vital importance.

Fatty growth on the heart, or *fatty infiltration*, is a condition which, though widely differing from the above, nevertheless should be treated pretty much upon the general principles just enumerated for fatty degeneration. Dietary being, however, a matter of the most important consideration, the reader is referred to the remarks under *Obesity*. *Oertel's* method, consisting of a combination of diet and exercise treatment, in which mountain climbing is a prominent feature, has been tried, but its dangers must not be overlooked. An open-air life, with abundance of walking, cycling, and golfing, may be freely advocated, but this must at first be gradually indulged in, and at a later stage more active exercises may be permitted. Some success has followed *Thyroid feeding*.

HEART—Hypertrophy of.

In the *Lumleian Lectures* *Broadbent* ably puts the question of treatment in this condition in a nut-shell when he says—"The treatment of hypertrophy as such has always appeared to me to be out of place."

The symptoms which may strike the student as calling for remedies are often irregular or painful palpitation, *præcordial*

distress, &c., and these, even in aortic obstruction with enormous hypertrophy, may be but evidence of the beginning of failing compensation, and the agents demanded are not sedatives, but cardiac tonics and rest. Belladonna Plaster applied and worn over the cardiac area is always a safe anodyne under nearly all circumstances.

In those rare cases of hypertrophy not associated with valvular affection small doses of Atropine have been used, but this agent is not to be pushed if it fails to give speedy relief. Strict dietetic treatment must be insisted upon, and, though tobacco is generally condemned, the writer has seen its very moderate use produce calm and tranquility, whilst Digitalis and cardiac tonics may increase the distress and palpitation. Iodides in a course of six to nine weeks can do no harm, but often are highly beneficial. Where there is fibroid degeneration or contraction of the kidney, the only sound plan to pursue is to treat the primary affection by increasing every possible means of producing elimination of the retained excrementitious products allowed to accumulate in the system, and which cause contraction of the capillaries and small vessels, and produce increased arterial tension.

HEART - Valvular Lesions of.

There is hardly any department of treatment requiring more serious study than that of the management of cardiac valvular diseases. There is none where a close attention to details will better repay the practitioner. His experience is, indeed, limited, and his treatment of these cases unsuccessful, who cannot at once call up instances where he has seen life prolonged for many years, and where he has felt that by the judicious use of remedies patients have been "called back" from the brink of the grave.

Under Endocarditis is mentioned the treatment of the condition out of which the valvular affection arises. After recovery from the rheumatic attack and its cardiac complication, the value of prolonged rest and other measures is insisted upon as the best hope of preventing permanent valve mischief. Iodide of Potassium at this time may be hopefully administered.

If after a time, when the patient has returned to his usual occupation, the physician finds that the permanence of the murmur tells that obstruction or regurgitation has resulted, the question of treatment crops up. There is some danger that an error may be committed at this stage. The appreciation of the mischief and danger of dosing every patient in whom a cardiac murmur is audible marks a distinct advance in cardiac therapeutics. Nevertheless there are not wanting signs which show that the pendulum has swung too far. If the dictum holds good that cardiac tonics should not be prescribed till failing compensation is evident, then, of course, nothing should be done in the early stages. This is true in the great majority of cases coming under the eye of the physician for the first time, but occasionally

he meets with symptoms clearly indicating that the ventricle has not yet sufficiently responded to the extra demands made upon it. In other words, the case falls under his observation before compensation has had time to occur. He will probably find in such cases that the patient has resumed his usual avocation too early, or that there may be some serious error in nutrition.

The treatment of such a case must be carried out by the judicious use of cardiac and other tonics, with rest. The condition closely resembles that of a patient who has long been the subject of a valvular lesion, and in whom compensation is beginning to show signs of failure. The precordial pain, palpitation, and breathlessness may be regarded as indications for treatment just as if occurring in an old case. Their management will be considered when describing the treatment of failing compensation presently.

As a rule, however, the victims of valvular lesions do not chance to come often under the notice of the physician at this early stage.

Frequently, in the course of a routine examination, a regurgitant or obstructive murmur is discovered in a patient who is hardly conscious that he has a heart, so perfectly has the hypertrophy enabled the ventricle to meet the demands made by increased resistance. It is now accepted as a general rule, and there should be few exceptions to it, that the exhibition of cardiac tonics is not only uncalled for, but may do serious mischief in such a case. Indeed, it has been stated that the greatest misfortune which can overtake such a patient is to fall into the hands of a physician, and it cannot be doubted that often ignorance is bliss under such circumstances.

To remove the diseased condition is obviously an impossibility in the present state of our knowledge and with the present resources of our art. Were such a result attainable it would be a serious question to decide upon disturbing the perfectly-balanced compensation. Consequently, the most that one is justified in doing is to consider what steps, if any, are necessary to maintain the perfect adjustment. A little reflection will show that the adjustment will probably be best kept up by a continuous adherence to those rules or habits under the influence of which such complete compensation has already developed. This should be the key-note to our advice and management of the case. Nevertheless, the physician should make minute inquiry into the habits and mode of life led by the patient. It is just possible that compensation has taken place, in spite of the violation of some law of health, and that continued transgression may be certain to ultimately induce failure as the patient gets older. Hence, errors are to be judiciously sought for and wisely remedied without exciting the alarm of the patient, who should not be led to regard himself as an invalid or a cracked pitcher which every contact with the rough world may shiver into fragments.

Temperance in all things is essential to a prolonged career under such circumstances. Excess in alcohol and tobacco, sexual excitement, severe business high pressure, mental over-strain and worry, and prolonged severe muscular exertion should be avoided. A fair amount of muscular exercise is not only unobjectionable, but it is really essential, in order to keep the cardiac muscle in a healthy condition. The physician is more liable to err in limiting than in encouraging the necessary amount of exercise. Walking may safely be indulged in to any reasonable extent, especially upon level ground. Even mild gymnastic exercises are productive of good under certain restrictions. Short spurts of running, lifting heavy weights, and violent quick movements are to be forbidden.

Everything likely to maintain a high standard of health should be advised, and a good liberal mixed diet prescribed, such as experience has proved to the patient to be most acceptable and sustaining. The writing out of a diet table for the subject of a valvular lesion in which compensation has taken place is a mistake. As far as possible the patient should be guided by his own instincts and experience in eating, avoiding much tea and all indigestible substances.

The earliest symptoms of failing compensation should be looked for with a watchful eye by the physician. They are the real indications for active treatment, and early failure of compensation generally is easily remedied. Perhaps this is the best example furnished by practical therapeutics of the truth of the adage—"A stitch in time saves nine."

Palpitation, cardiac pain, breathlessness, dyspnoea, cough, blueness of the extremities, oedema of the ankles, passive congestions of the liver, stomach, intestines, and kidneys, and slight albuminuria are to be regarded, not as so many different symptoms, each requiring its specific remedy, but as the direct outcome of one cause, which requires remedying.

Before mentioning the different drugs which may be used to strengthen and build up again the debilitated muscular walls of the dilated ventricle, it may be advisable to consider other important aids to treatment, as diet, exercise, &c.

The exact valve affected and the nature of the affection, whether resulting in obstruction or regurgitation are of comparatively minor importance, the secondary changes in the cardiac muscle and in the ventricular cavities demanding primary consideration.

Diet should be of the most nutritious and sustaining character, consisting of a fair amount of nitrogenous food with small proportion of fats and saccharine matter. It has been pointed out, in detailing the lines for the management of cases of valvular lesion in which complete compensation has taken place, that there is a serious objection to prescribing a fixed diet or bill of fare. In the treatment of the cases now under consideration, there are stronger reasons why this should not be followed. A theoretically

constructed diet table for failing compensation is very good upon paper, but at the bedside it is of little use; the value of a dry diet was insisted upon by Sir A. Clarke in mitral stenosis, and the importance of restriction in the amount of fluids in the food is an essential element in Oertel's treatment.

Dyspepsia depending upon passive congestion of the gastric mucous membrane is a pretty constant early symptom, and it resents attempts to sustain life by obedience to hard and fast lines. For this reason rectal feeding is of vital importance in many cases for a brief time to give the flagging stomach a little rest.

Leube's bland nutritious enema suits such cases well. 1½ ozs. of muscular fibre is beaten into a smooth paste, with ½ oz. of finely-chopped pancreas free from fat in a warm mortar with a little lukewarm water, to give suitable consistence. The whole may be injected every six hours. Peptonised Beef Tea or Roberts' Peptonised Milk Gruel may be used. Cold Milk is added to an equal quantity of thick Oatmeal Gruel, at a temperature of 212° F. About three-fourths of a tea-spoonful of Liquor Pancreaticus and 5 grs. of Bicarbonate of Soda are added to 5 ozs. of the mixture.

Sansom recommends an easily-prepared enema, consisting of 2 ozs. warm Milk, shaken up in a bottle with 1 oz. Cod Liver Oil. He says — 'I feel sure from my experience, that lives may be prolonged and crises tided over by such supplementary alimentation' — a statement that the writer's experience has proved true.

The most convenient of all methods of rectal feeding, when expense is no object, is the use of a good nutrient suppository. It is, of course, understood that rectal feeding is only to be employed in those advanced cases where the patients are unable to eat and digest.

Oertel introduced a method of treating failing compensation by a combination of diet and exercise. Exercise was formerly considered as contra-indicated. The introduction of this treatment may be regarded as a protest against the practice of enforced rest in chronic valvular lesions. Oertel tried it first in cases of fatty heart associated with general obesity, and his results were so striking that he applied the treatment to valvular lesions.

The rationale of the plan is based upon the doubtful assumption that the blood in these cases contains an undue proportion of water. Hence he believes, if this can be removed by a diminished supply and increased excretion, the work which the heart is called upon to do and the congestion of organs will be lessened. Of all the methods for increasing the elimination of water he has proved that none equal *mountain climbing*. About one quart of water, he found, was excreted by the skin and lungs after an ascent of over 1,000 feet, made in a climb of rather less than four hours, the urine not being materially altered in quantity. At the same time the heart is stimulated to more forcible contractions, and the muscular exercise has powerful influence, through the relations of the great veins to the fasciæ, in quickening the venous

and arterial circulations. The result is, that in the long run a genuine and healthy hypertrophy of the cardiac muscular fibre takes place.

The quantity of fluid ingested he reduces to an amount under one quart daily, inclusive of that contained in the solid constituents of the food.

The diet should be highly nitrogenous, consisting chiefly of proteids, with a little fat and a limited amount of carbohydrates.

He lays down a strict diet table, in which the total food for the 24 hours amounts to about—

5½ oz. Albumin, 1 oz. Fat, 3 oz. Carbohydrates, 35 oz. Water.

Of the 35 oz. of water a little less than half is contained in the solid food, and a little more (about 1 pint) is to be given as drink. Thirst may be relieved by frequent gargling with water.

The following is a summary of the articles included in such a diet, with the approximate quantities in English weights and measures —

Morning Meal—Coffee ¼ oz., Milk 1 oz., Sugar 77 grs., Wheaten Bread 1½ oz. Mid-day Meal—Soup 3 oz., Roast or Boiled Beef, or Veal, or Game, or Lean Poultry 7 to 8 oz., Fresh Salad 1 oz., Bread 1 oz. (never to exceed 3 oz.) Fruit 3 to 6 oz., a little Fish if desired. Light Wine, 6 to 8 oz. if no fruit or if very hot weather, otherwise no fluid with this meal. Afternoon Meal—Coffee ¼ oz., Milk 1 oz., Sugar 77 grs., Water 2 oz. (never more than 6 oz.), Bread 1 oz. (exceptionally). Evening Meal—Wine 7 oz., Water 2 oz., 1 or 2 Eggs, Roast Meat 5 oz., Salad 1 oz.

Since the above dietary is intended for those cases of fatty heart associated with obesity, its use is a serious mistake when applied to cases of ordinary failing compensation in which obesity is not a prominent symptom. It is inserted here to give a bird's eye view of Oertel's plan of practice. (See under Obesity.)

This method has been received by different authorities with very varying degrees of favour or hostility. The writer has had no experience of its working whatever, though he has had ample proof of the benefits of moderate exercise and very mild gymnastics in failing compensation.

From a very careful study of the experiences of others it would appear that occasionally in selected cases it is a valuable addition to cardiac therapeutics. The cases in which it gives best results are in very fat subjects, in the anæmic, and in those complicated with gout, as pointed out by Sansom. Yeo condemns this system, and states that it has already fallen into discredit and disuse even in the country in which it originated. Some still recommend it in chronic valvular affections where compensation has not been lost.

Oertel has admitted that it should not be attempted where there is very serious incompetence of the cardiac muscular fibre, or where there is atheroma, nor should it be persisted in where

dyspnoea is increased, or the excretion of urine diminished under its use.

Modifications of the plan may be carried out by regulating the diet so as to materially diminish the amount of fluids consumed, and to increase the amount of urea and water eliminated by means of the hot air bath and hot packs, combined with the use of the cardiac tonics to be presently mentioned.

If to these be added systematic and judicious muscular exercise upon level ground, and a careful and thorough course of massage, all the benefits of Oertel's treatment, without its *serious dangers*, may be procured. The Schott method in vogue at Nauheim consists of baths of weak Saline solution in combination with Carbonic Acid, and afterwards mild gymnastic exercises involving flexion, extension, and rotation movements under the restriction of a competent attendant. Or, as defined by Thorne, "They consist of movements which should be performed under the immediate direction of the physician, subject to a certain measure of resistance offered either by him or by a carefully-trained assistant, and successfully applied to the upper extremities, trunk, and lower extremities." As the entire system of Schott can only be carried out by most patient attention to numerous details beyond the scope of this work, the reader will find an able paper upon it by Bezly Thorne in the *British Medical Journal*, March 9, 1895. The method is applicable to all forms of cardiac enlargement and dilatation (including aneurisms), save where there is advanced arterio-sclerosis. The reported results are most remarkable and surprising, and it is claimed that the diminution in the size of the heart is permanent.

The artificial effervescing Nauheim bath can be administered to any patient in his own house, as every first-class chemist can supply the materials, and the writer has personally on several occasions tested this method, when combined with a natural sulphur-water bath, at Harrogate, where an excellent Nauheim-sulphur bath can be easily obtained.

The plan of massage and hot douches, as practised at Aix-les-Bains and recommended by Sanson, has been productive of much good in the experience of the writer, who has had patients return very much improved after a short course of treatment.

The Swedish or the Zander system of gymnastic exercises or graduated movements may be tried in many cases with success.

Treatment by Drugs.—After evidence of failing power in the cardiac muscular fibre has been established the question of the administration of cardiac tonics should immediately suggest itself.

It cannot be too strongly insisted upon that at the beginning of treatment for failing compensation, in order to get the best results from drugs, absolute rest in bed for a short period, even in mild cases, is essential.

One point may be here mentioned, the consideration of which may save the physician from falling into a not uncommon error. Remembering that a patient (in whom perfect compensation may exist) lives in a state of not very stable equilibrium, the transitory disturbances caused by severe mental emotions or other trying causes should not be mistaken for the onset of permanent failing compensation. In aortic disease especially, such passing disturbances may give rise to painful palpitations and distress where great hypertrophy exists. The passing symptoms in such cases would probably be aggravated by Digitalis and other cardiac tonics. Sedatives like Aconite, Bromides, or Iodides afford marked relief. (See page 385.) Their use should not be continued for any length of time. The permanence of the symptoms points to loss of muscular power rather than to altered innervation, and then cardiac tonics are called for.

When palpitation, præcordial pain, breathlessness, pulmonary or other congestion, and commencing œdema show themselves in chronic valvular lesions, cardiac tonics should be given without loss of time.

Digitalis, notwithstanding the introduction of a host of rivals, stands as the most reliable member of the group of cardiac and vascular tonics. By acting as a true tonic to the cardiac fibre, it increases the tone of the heart, produces slower and stronger contractions, allowing the left ventricle to drive a larger volume of blood into the aorta at each stroke. At the same time it causes a more perfect adaptation of the segments of the mitral valve by lessening the size of the orifice. It prolongs the diastole, thus permitting the more complete filling of the ventricle in mitral stenosis, and at the same time it strengthens the power of the auricle. The prolongation of the diastole benefits the circulation in the cardiac fibres and improves their nutrition.

Wood regards Digitalis as a heart food and tonic, and not as a cardiac stimulant. According to Romberg's views about the importance of regarding the myocardium and not the ganglia as the automatic motor of the circulation we must come to the conclusion that the drug acts strongly upon this portion of the cardiac apparatus also.

By causing increased contraction of the small arteries and capillaries, Digitalis raises the blood pressure and so affects the lymphatic and venous circulations as to exert a powerful influence upon dropsy. Through its effect upon the vessels, it also acts as a powerful diuretic, and may be made to cause enormous increase in the amount of urine secreted, especially when the patient is almost "water-logged."

These valuable actions of Digitalis may be successfully employed in valvular lesions with failing compensation, and by its intelligent use life may be prolonged for indefinite periods under conditions of comparative comfort.

The dose will vary somewhat according to the condition of the patient and the nature of the lesion and other considerations to be mentioned.

Various opinions prevail regarding the relative values of the different preparations of the drug. The tincture of the B.P. (1 grain in 8 minims) is the most convenient form, but where a purely cardiac tonic effect is only required many authorities state that the infusion is to be preferred.

The tincture, however, has the great advantage of being more powerfully diuretic, and as dropsy is a very constant feature in the late stages of failing compensation, the tincture is the best preparation in the majority of instances.

Owing to the danger of accumulation taking place the action of the drug should be watched for a week or two with care. As a rule in moderate doses (5 to 10 minims) it may be administered for years without producing any unpleasant symptoms. As long as the quantity of urine excreted is of fair amount the drug is eliminated by the kidneys, and its cumulative action is not experienced. Where large doses are considered necessary the patient should be kept in the horizontal position, and the administration should be stopped as soon as the blood pressure rises so high as to seriously diminish the amount of urine.

Sansom lays stress upon the rule that average doses of the drug at intervals of four hours should not be continued in the earlier stages of treatment for more than three days, then the drug should be suspended for a like period, and that it is only when a patient manifests a perfect tolerance that the protracted administration should be permitted. The writer has very seldom seen a necessity for such precautions; the remedy is perfectly harmless in doses say of 7 to 8 minims of the B.P. tincture.

Digitalin or Digitaline is recommended by many authorities, but it is safe to say that none of the isolated principles from digitalis leaf give the same powerful and safe effect as the leaf itself, or its tincture, or infusion. Nativelle's granules or syrup are, however, highly recommended by many London physicians, and Digitaline affords a satisfactory method for hypodermic use, though the writer has generally injected the B.P. tincture. Nativelle's Crystalline Digitaline may be injected in doses of $\frac{1}{10}$ grain to $\frac{1}{5}$ grain. It consists chiefly of Schmiedeberg's digitoxin, and is cumulative and potent, the maximum dose by the mouth of Homolle's Digitaline, Nativelle's Crystallised Digitaline, or Schmiedeberg's Digitoxin, or Merck's Digitoxin, should not exceed $\frac{1}{10}$ grain. The pure Digitalin of German commerce is a mixture of the digitalis glucosides, and may be given in doses of $\frac{1}{10}$ grain. It may be given hypodermically ($\frac{1}{4}$ gr.).

Iron may be combined with Digitalis nearly always with marked advantage, as anemia is commonly present. The following formula makes a bright mixture—

R. *Tinct. Digitalis* ℥iii.
 Tinct. Ferri Perchlor. ℥iii.
 Acid. Phosph. Dil. ℥ii
 Glycerini Purif. ʒj.
 Aqua Destil. ad ℥iv. *misce.*

Fiat mistura. Sumat ʒi ex ʒii. aqua quater in die post cibos.

The relative value of digitalis in the different valvular lesions may be briefly stated.

In mitral regurgitation, the effects of the drug are seen to best advantage. As already stated, it lengthens the diastole, and gives a longer period for cardiac repose and nourishment of the muscular fibre. It diminishes the size of the mitral orifice, and ensures the more complete filling and subsequent emptying of the ventricle into the aorta. By its similar tonic action upon the right ventricle, it enables it to overcome the increased resistance to the pulmonary circulation, and lung congestion disappears. The increased ventricular power thus gained, together with its tonic effect upon the vessels, reduces the pressure in the venous system, and dissipates the general congestion of organs and dropsy. The blood pressure rises, and the pulse slows whilst it gains in force and regularity.

In mitral stenosis, the action of digitalis is not so satisfactory. In many cases the narrow chink or funnel-shaped mitral orifice permits of regurgitation. In considering such cases, it becomes a question of the degree of obstruction and its relation to the accompanying regurgitation. Is there more of obstruction than of regurgitation in the affection? One may come to a conclusion that may be formulated in the following therapeutic rule:—In proportion to the extent of the obstructive lesion, so will the effect of digitalis be disappointing; and, conversely, the more regurgitation taking place, the more improvement may be expected from digitalis.

In pure obstruction the drug often cannot be tolerated, and though sometimes it appears to strengthen the dilated auricle, and by lengthening diastole to give the blood a longer time to flow through the narrow valve, nevertheless it may increase irregularity of the pulse and cardiac distress. It should, however, be given in every case a fair trial, and, after failure, other cardiac tonics may be tried.

In aortic obstruction, if digitalis be given too early—i.e., before failure of compensation has taken place—very serious disturbance may be caused by it, owing to the enormous hypertrophy commonly present. Where there is marked failure of the enlarged ventricle to drive the blood through the narrowed aortic valve, digitalis acts

most satisfactorily. It may always be counted upon in such cases, but more care is needed in its administration than if the affection was mitral regurgitation.

After the ventricular strength has been restored and compensation again adjusted, the use of the drug should be stopped. It may, however, be again commenced as soon as evidence points to ventricular weakness, the prolonged, continuous rise in blood pressure being undesirable in aortic stenosis, owing, as suggested by Bramwell, to the risk of rupture of the diseased peripheral vessels.

In aortic regurgitation, the case is not so easily made out in favour of digitalis, and there are still sharp differences of opinion regarding the benefits and dangers of the drug in this affection.

Brunton, with his usual clearness and force, has ably defined the indications and contra-indications. He points out that, owing to the diseased valves failing to close in diastole, the arterial system is open at both ends, and thus a fatal syncope may be induced by a fall in blood pressure. This occurs in a small percentage of cases, and the tendency to it cannot be wisely overlooked. Anything which prolongs the period during which the backward flow of the stream into the ventricle is taking place increases the danger of syncope. Hence digitalis, by prolonging the diastole, may increase this danger. He points out how such danger may be minimised during the administration of the drug, by insisting upon the patient keeping in the horizontal position, with the head lowered.

When, however, the change in the left ventricle proceeds so far as to permit of mitral regurgitation by imperfect closure of the mitral curtains, Digitalis is called for. Where mitral regurgitation takes place from the first through structural alterations in the auriculo-ventricular valve, the drug gives excellent results.

Again, in cases of pure aortic regurgitation, without any mitral regurgitation at the later stages, where failing compensation is marked, and the pulse becomes frequent, irregular, and weak, the failing cardiac muscle calls for Digitalis. Pulmonary embarrasment, breathlessness, congestion of organs, and dropsy disappear under its use. The drug should be discontinued as soon as compensation is thoroughly established.

Allbutt dwells upon the power which Digitalis has of increasing the tone of the ventricle apart from its contractility. He defines tone as that property which preserves the mean diameter of the cavity (if tone were absolute there would be no dilatation). In aortic regurgitation, where the left ventricle is too capacious and its apex beat diffuse, provided the muscle is sound, Digitalis will be very valuable. He gives one dose of the tincture (10 mins.) every second day, and watches the effect on the flow of urine and the rate and rhythm of the pulse. If no harm results he continues the drug, but he thinks it never is indicated in this condition if

the pulse keeps under 75. In a later stage, when the right side of the heart is involved, the drug is rarely harmful.

Fürbringer states that he does not know of a single anatomical contra-indication to the use of Digitalis.

The other cardiac tonics which have been of late years employed as substitutes or aids to Digitalis are—Strophanthus, Caffeine, Casea, Convallaria, Adonis Vernalis, Squill, Sparteine, Chloride of Barium, Senega, Arsenic, and Strychnine.

From time to time each of these has been lauded as a remedy certain to displace Digitalis, too often the statement has been made upon the experience gained in a few cases in which Digitalis has been found to disagree with the patient's appetite or digestion. All one can say is that, in the present state of our knowledge of the relative values of the members of the group, given a case of failing compensation, the first drug to prescribe is Digitalis. When it fails Strophanthus may be tried then Caffeine and Sparteine. Though much has been written upon these drugs, the action of no member of the group has been as fully worked out as in the case of Digitalis. Probably the experience of the writer has been that of nearly every physician in this matter. It may be summed up by saying that when in the management of a serious case of failing compensation, pulmonary engorgement and a halting ventricle warn us that unless we come to close quarters with the enemy our patient must succumb, then every other drug is thrown aside and we invariably fall back upon Digitalis. The serious and pressing nature of the case does not justify one in experimenting with the different members of the group of cardiac tonics, hence the experience at present gained is for the most part accumulated from cases in which these drugs have been administered in the earlier stages of failing cardiac power. The results of this system of skirmishing "at long range" can hardly be judged side by side with the records of the older cardiac tonic.

There are, however, several well-marked differences in the actions of some of these remedies already worked out by the pharmacologist. Thus Strophanthus has little diuretic action, certainly it has less diuretic action than Digitalis, though some observers have recorded instances where it markedly increased the amount of urine. It acts more powerfully upon the heart than digitalis does, and it has less action upon the arterioles, the rise of blood pressure being nearly all owing to its cardiac action, unlike what happens with digitalis.

The brilliant researches of Fraser have shown that the action of Strophanthin, in minimum lethal doses, shows itself by great increase in the strength and in the duration of systolic contraction, and the ultimate standstill of the heart in this contraction passing into *rigor mortis*. He points out that this increased duration of contraction, with lessening of the dilatation and capacity of the chambers, is not the action likely to be serviceable in weak conditions of the organ or in the existence of disabling

lesions. By giving smaller doses he demonstrated *great* prolongation of the diastolic pause, though the interrupting systolic contractions were strong, and completely emptied the ventricles of their large accumulation of blood. Thus he has solved what would have been a problem fraught with enormous difficulties and fallacies at the bed-side, i.e., that *strophanthus* greatly increases the working capacity of the heart, by increasing both diastole and systole through its stimulating effect upon the muscular fibre itself and its influence upon a portion of the intra-cardiac nerve apparatus.

It certainly has this advantage over *digitalis* that it possesses little, if any, cumulative action; but it sometimes causes gastric and intestinal disturbances. It can, however, be given to great advantage in the intervals during which *digitalis* is suspended, and the writer finds it an excellent plan to give *digitalis* for two months, and after three days pause to give *strophanthus* in similar doses, combined with *Easton's Syrup* for one month, when the *digitalis* may be again commenced.

Caffeine.—There is still much difference of opinion regarding the cardiac tonic action of this drug, some authorities going so far as to declare that it possesses no *digitalis*-like action upon the heart, and that its diuretic action is simply owing to its local influence on the renal epithelium. Other observers report very satisfactory results in failing compensation, and the writer believes that he has seen excellent results from the administration of 3 to 5 gr. doses of the citrate in mitral regurgitation, with much anasarca and congestion of organs, where *digitalis* was not well borne.

One advantage it certainly possesses over *digitalis* which will continue to give it some position in cardiac therapeutics—i.e., that its diuretic action is more rapid than that of the old-established remedy—an advantage of great importance in some cases where time is of primary consideration. Allbutt, who recommends *Merek's Pure Caffeine*, gives it as a cardiac stimulant in aortic regurgitation where the pulse is slow and the heart flagging, and where *digitalis* is not admissible. When the evening or night dose is omitted there is little risk of insomnia, and it can be advantageously combined with *digitalis* or *strophanthus*. D. Beaumetz pointed out that it is given in doses which are of little value, and he insisted that with the daily dose of half a drachm marvellous effects may be noticed.

Convallaria does possess some cardiac tonic powers, but the test of time is telling seriously against its claims as a substitute for *digitalis*. At present the consensus of opinion is pointing to a rule which is being gradually formulated that the drug should only be tried when *digitalis* fails, or that its use should be confined to the treatment of mitral stenosis, in which disease, as already stated, *digitalis* very often fails.

In mitral stenosis and aortic regurgitation it has often been found to slow the pulse, strengthen the ventricular contractions,

relieve dyspnoea markedly, and remove dropsy. It may be given in combination with caffeine in these cases with advantage.

Sparteine produces rapid cardiac tonic effects. It acts in most respects like digitalis, but is much quicker in its action, and hence where a rapid result is required it may be given with advantage in doses as large as 3 grs. every 6 or 8 hours. Its diuretic action is markedly inferior to that of digitalis. Given a case of rapidly failing compensation, sparteine may be ordered in full doses immediately, and after a few days, when its effect appears to be on the wane, digitalis may be administered with much benefit. Like all the other members of the group, it may be given with advantage during the intervals in which digitalis is suspended during a prolonged course of that drug.

Chloride of Barium has been much praised as a cardiac tonic. The writer has had no experience of the drug, and can only speak from the published reports of those who have tried it in failing compensation. It possesses power closely resembling digitalis. It slows the pulse very markedly, and regulates its rhythm, raises the blood pressure by its cardiac and vascular stimulation in doses of one drachm of a one per cent. solution, which is tasteless and unobnoxious to the stomach. It has been given in all forms of valvular lesion, and no ill effects have been noticed. Most observers have stated that it relieves cardiac pain and is a mild diuretic, but notwithstanding these roseate reports, the drug has not come into general use.

Mitchell Bruce dwells upon the great value of hypodermic injection of Strychnine in 1 per cent. solution, which, he states, has in some instances an effect little short of the marvellous in restoring the action of the ventricles. This is a point of the greatest importance since the action of digitalis is slow, and in urgent cases strychnine should be given hypodermically while awaiting the full action of digitalis. The writer's experience fully confirms the numerous statements recently made about the great value of this drug in failing compensation. He now uses it in the treatment of every severe case in combination with cardiac tonics, and those who have not found marked benefits follow its use have probably given it in doses which are worthless. Allbutt states that 15 min. of the liquor are not too much for a single dose.

Adonis Vernalis, *Adonis Aestivalis*, Squill, Senega, Cactus *Grandiflorus*, *Carduus Marian*, Coca, Coronilla, *Apocynum Cannabinum*, and many other cardiac tonics have been from time to time used in failing compensation, but it remains to be proved that they possess any advantages over those already discussed, and some of them are most unreliable.

Recently Stern advocates strongly the virtues of Adonidin—the active principle of *Adonis Vernalis*—in cases where digitalis is contra-indicated, as in fatty heart, failing compensation, &c. It acts as rapidly as Trinitrin; $\frac{1}{2}$ grain very quickly reduces oedema and raises the blood pressure, and it is not cumulative.

So many points remain for "clearing up" in the action and therapeutics of the better known members of the cardiac tonic group, that the ceaseless introduction of new rivals is actually becoming a serious barrier to therapeutic progress. At the head of the entire list still stands digitalis, and of all those below it, the most that can be said of them is that they are of value when it fails or disagrees, and that they may be administered with advantage when it is considered wise or expedient to leave off its use for short periods.

Arsenic is said to be of special use where there is evidence of degeneration of the cardiac fibre having taken place to any extent. It may then be combined with strychnine and iron. Broadbent believes in free Phosphorus, and considers it superior to Arsenic. Some authorities recommend a combination of the various cardiac tonics at the same time, but the more we know of cardiac physiology the less likely is a conglomeration of crude drugs to meet the indications of the case.

At this place no mention is made of ether, alcohol, ammonia, &c., which are often classified as cardiac tonics, but it is needless to say they possess no such action, being simply cardiac stimulants whose place in medicine is to be administered when a rapid stimulation of the feeble cardiac muscle is required, whilst other remedial agents are getting time to exert their more permanent influence.

There are various prominent symptoms or complications which often arise during the later stages of valvular lesions, the treatment of which may be briefly referred to.

Bearing in mind that these symptoms for the most part take their origin in the disturbed balance produced by failure in the cardiac muscular fibre, their successful management will generally mean the administration of cardiac tonics. There are however, other remedies which the physician may call to his aid when the urgency of the symptoms does not justify him in waiting for the comparatively slow action of these drugs.

Dropsy may threaten the patient's life from oedema of the lungs before Digitalis has time to act, and the general rules laid down in speaking of the treatment of Bright's disease are for the most part applicable to the anasarca which results from valvular trouble. In the former case, however, the kidneys being more or less crippled in their action, diuretics are of comparatively little avail, and may be even dangerous, whilst in cardiac dropsy the physician can for the most part count upon their co-operation.

The diuretic action of Mercury in cardiac dropsy is most marked. Finkelstein's method is to give $\frac{1}{2}$ to $\frac{1}{4}$ gr. Calomel every two hours for 4 or 5 days, and then to add about half this amount of Digitalis. Rarely is purging or mercurialisation noticed, and if it appears, the suspension of the drug removes it at once. The diuretic effects appear about the fifth day and continue for ten days after suspension of the drug. The urine often reaches

1½ gallons daily. Beatty gives ½ gr. Calomel with Squill and Digitalis every four hours night and day for a fortnight in cases of heart disease with general venous engorgement. Others give one large dose of 5 to 10 grs. Calomel, but serious prostration may follow either method, and disastrous results will follow if there be any chronic nephritis present.

Iodides are valuable. They may be combined with great advantage with other diuretics and with digitalis. The following is a good combination:—

R. *Sodii Iodidi* ʒij.
 Spt. Ammon. Aromat. ʒiv.
 Succ. Scoparii ʒiss.
 Tinct. Digitalis ʒii.
 Infus. Senegæ ad ʒvi. *misc.*

Fiat mistura. Capt. cochleare magnum sextis horis ex aqua.

In addition to its diuretic action the Iodide appears to act as a true cardiac tonic like Digitalis, at the same time it possesses the power of relieving cardiac pain and distress, especially in those cases where there is degeneration of the vessels. The writer believes that most authorities will agree with him when he states that the great majority of chronic valvular lesions and their complications can be successfully treated by the four following drugs mentioned in the order of their merit:—*Digitalis, Strchnine, Iodides, and Iron.*

Guy's or Baly's Pill, containing 1 grain each of Squill, Digitalis, and Blue Pill is an invaluable remedy where there is no urgency.

Nitroglycerin sometimes starts the kidneys in small and often repeated doses, as ½ minim of 1 per cent. solution every 15 minutes for 4 or 6 hours.

Where the kidneys fail to respond, the bowels may be made the channel for the removal of much fluid. Saline purgatives, as the ordinary hospital White Mixture, may be used for this purpose. Hav's method of purging by Concentrated Solution of Magnesia Sulphate (see page 89), may be employed where the general anasarca threatens to cause suffocation. Cream of Tartar may be used to keep up the effect of the purgative. *Pulv. Jalapæ* Co. is a favourite drug. Puncturing the limbs or tapping the peritoneum may be resorted to. Acting upon the skin, as in Bright's disease, by hot air and vapour baths and pilocarpine, is not satisfactory.

Diuretin, which is a sodio-salicylic compound of theobromine, has been used with some success in the dropsy caused by valvular disease. The dose should be up to one drachm and a half daily, i.e., about 15 grains every four hours. It sometimes

causes very marked increase in the urine and rapid disappearance of anasarca.

Lactose has been praised by Sée as the most powerful of all cardiac diuretics; 3 oz. dissolved in 4 pints of water is made to replace all other liquids. Enormous increase in the urine is said to follow. It should be stopped after 10 days and again commenced.

The general visceral congestions are to be relieved by the same means *i.e.* by combinations of various diuretics and by brisk saline cathartics. Dry cupping over the chest and loins may give relief.

Pulmonary embarrassment may come on rapidly, causing sudden and dangerous dilatation of the right side of the heart from the congestion of the lungs. In such cases life may be prolonged by making a good-sized incision into a vein in the arm and removing 10 oz. of blood. Leeching may be tried, but where the lividity and orthopnoea are sufficient to call for venesection, leeching is of doubtful value. Where leeching has failed, cupping over the hutes may do good. Ether and Ammonia should be given. (See page 383.)

Bronchial inflammations following congestion should be treated by brisk counter-irritants and expectorants whilst cardiac tonics are allowed time to act. The inhalation of Oxygen, and Compressed Air Baths have been recommended to relieve the dyspnoea.

Sleeplessness may be met by opiates if the bronchial surface is free. Chloralis doubly dangerous in cardiac cases with a weakened ventricle, but $\frac{1}{4}$ to $\frac{1}{2}$ grain Morphia hypodermically often acts most beneficially and relieves dyspnoea and orthopnoea and cardiac asthma. Parakdehyde, Trional and Sulphonal are unobjectionable, and many eminent authorities extol Chloralamide.

Syncope or sudden cardiac failure must be promptly met by Ether and Ammonia, hypodermically or by the mouth. The hypodermic injection of Strychnine is invaluable. Alcoholic stimulants and Sparteine should be freely given, and Brandy or Whiskey may be injected hypodermically or by the bowel.

Hypodermic injection of $\frac{1}{4}$ to 1 oz. of a 6 per cent. Salt solution causes rapid rise of blood pressure, which lasts for some hours.

A single induction shock may be tried with advantage.

Cardiac pain is often a troublesome symptom. It is best met with local applications. The B.P. Belladonna plaster over the heart affords surprising relief in many cases. This symptom is often associated with painful palpitations. For the relief of the abnormal cardiac action, accompanied by pain, in old valvular cases there is no remedy equal to large doses of Iodide of Potassium. The writer has obtained good results from the following combination —

R. *Tinct. Digitalis* *℥iiss.*
 Potassii Iodidi *℥iij.*
 Ext. Cocæ Liq. *℥ii.*
 Aquæ et Glycerini ad *℥iv. misc.*

Fiat mistura. Cpt. ℥j. ex ℥i. aqua quater in die post cib.

Germain Sée strongly maintains that the iodide is superior to all drugs in dilating the arterioles, diminishing the peripheral resistance, and enabling the heart to recover its contractile power, and at the same time, greatly promoting its nutrition. Laborde insists upon the Iodide of Potassium as being the true medication of the heart.

As pointed out by Broadbent, sometimes more good is done by diminishing the work which the heart has to do than by attempting to increase its muscular power. This is the probable explanation of the value of the iodides. By causing dilatation of the small vessels the peripheral resistance is so diminished that the heart has less to do, and when absolute rest is enjoined along with iodide treatment brilliant results may be attained where the ordinary cardiac tonics fail. This is the explanation which Broadbent gives of the value of the Schott system and carbonic baths—viz., the dilatation of the cutaneous and muscular vessels which results from the treatment materially diminishes the amount of work done by the heart.

Fraser, however, is unable to recognise any sufficient modification of the circulation produced by therapeutic doses of the iodide that can afford an explanation of the benefits following its administration.

Where the palpitation is liable to come on in severe attacks, Nitrite of Amyl or Nitroglycerin (see Angina, page 481) may be used. The value of Opium in relieving cardiac pain must not be overlooked, it causes rapid diminution of peripheral resistance and fall in the pressure which is however liable to rise again suddenly upon the withdrawal of the remedy.

HECTIC FEVER.

The first indication is to remove, if possible, the cause upon whose presence in the system the hectic depends. Any suppurating cavity should be freely incised, washed out, and drained. Diseased bone and affected joints should be excised, and every source of supuration dealt with upon general surgical principles.

Empyema, tubercular lesions of the bowel, lung, and kidney, tend to wear out the patient through the hectic which they produce, and where the cause cannot be removed the febrile symptoms may be kept in check. Sometimes, if the patient can be kept alive for a sufficient time, the cause of the hectic may wear itself out,

and in such a case palliative treatment is of the greatest importance.

The diet should be most sustaining, being given in the most concentrated form at very short intervals and, of course, in moderate quantities at a time. Alcoholic stimulants may be freely administered, and everything that supports the patient's hopes and encourages sleep, appetite, and digestion must be carefully attended to. Abundance of pure, warm, dry air is of much importance in checking the suppurative process.

The paroxysm of chills, fever, and perspiration can be modified or prevented by antipyretics. Under Phthisis the action of these remedies and the treatment of night-sweating will be considered.

In the early part of the paroxysm during the chilly stage a little warm stimulant may be given, and when sweating is profuse, the skin may be freely sponged with cold or hot water and Vinegar, to which a little Tincture of Belladonna is added. Before the rise of temperature is expected, a moderate dose of Antipyrine or Antifebrin (10 grs. of the former or 6 of the latter) will effectually prevent the paroxysm altogether, or so modify its intensity as to cause little waste or exhaustion.

In severe and prolonged cases 10 grs. of Antipyrine may be given, and half this dose, repeated in one hour, if the temperature does not fall, should the fever not yield to the second dose, 5 grs. may be given in another hour (20 grs. in all).

After a full dose given in this way, a fall from 104° to 100° or 98° may be confidently expected, and the fall may last for 24 hours or more. Sometimes rather alarming prostration follows this treatment, but though the writer has never seen serious symptoms follow, he has latterly given up large doses when the fever is high for small ones given before the expected rise. Under Phthisis the management of this condition will be more fully considered.

Quinine is a drug of great value, and it may be given in 5 gr. doses and where it checks fever, it may be continued for any length of time.

Guaiacol externally applied acts as an antipyretic in feverish conditions. Its drawback is that also of antipyrine, viz., profuse sweating. Creosote acts in the same way. 20 drops of Guaiacol rubbed over the skin of the abdomen for two or three minutes, and covered with oiled silk, cause generally a drop to normal in the temperature in about two hours, but serious collapse has so frequently followed its use that the drug should not be employed for this purpose.

HEMICRANIA—See Megrin.

HEMIPLEGIA.

Under the head of Apoplexy the treatment of hemiplegia in its first stages has been described. After the patient has recovered in every other respect from the seizure which caused his attack,

the only symptom remaining may be the loss of power in the muscles of one side of the body.

The treatment at this stage must be directed to his general condition, little can be done for the paralysis. The bowels and bladder must be carefully looked after, cathartics or laxatives being necessary in most cases. Drugs are of little use in hastening the disintegration and absorption of the clot upon which recovery depends, active interference being fraught with danger. Strychnine is liable to increase the mischief, and its utility in the early stages of the affection is *nil*. At a late stage it may be of much value. Bromides with Iodides may be tried, and at a later stage Phosphorus in small doses may be beneficial. The diet should be sustaining but unstimulating, and the less animal food and alcoholic stimulants the better. A pure vegetarian diet with milk is indicated. Mental repose should be maintained. When the patient is able to move about, the natural exercise will improve the nutrition of the affected muscles. For the first month no attempt should be made to stimulate them, but gentle friction cannot do harm. As long as symptoms of cerebral irritation exist, massage and electricity are contra-indicated.

When a couple of months have elapsed, and the only sign of trouble that is evident is weakness in the affected muscles, massage should be cautiously commenced and fairly tried, and, along with it, electricity. The current applied to the muscles of the extremities may be the continuous or Faradic, the latter being used only after a few weeks trial of a weak continuous current. If contraction of the fingers threatens early, gentle passive movements may be tried, and a weak continuous current applied to the extensor muscles. Different opinions prevail about the wisdom and utility of attempting to reach the lesion itself. The writer has seen decided benefits follow the application of a current from five Léclanché elements, with one large electrode upon the forehead and the other over the occiput. After a week the current strength may be doubled, and he has employed ten cells, causing the current to flow from an electrode placed over the site of the hæmorrhage on one side, with the other pole situated over the opposite region of the skull. Free exercise may be permitted, and every factor likely to cause a return of the hæmorrhage, as increased blood pressure, should be carefully guarded against.

Horsley has recommended the ligature of the common carotid trunk as a prophylactic measure against further hæmorrhage in those cases where a slight cerebral hæmorrhage has already occurred. (See under Apoplexy, page 59.)

The plan of trephining, with the view of reaching the clot, has not yet passed beyond the experimental stage, but the success of mercurial treatment in syphilitic cases is beyond question.

HEPATITIS—See Liver Diseases.

HERNIA.

The treatment of abdominal hernia is outside the scope of the present article. Only a very brief account of the management of a few of the many forms commonly met with need be given. Such methods will be mentioned as may be useful when the urgency of the case prevents the medical attendant consulting any of the text-books or standard works on surgery.

Given a case of *recent* hernia in a patient hitherto free from any symptoms or signs of the affection, the first duty of the surgeon should be to effect its reduction. After its return (when reducible) the palliative treatment, by means of a suitable truss, is generally deemed all that is necessary.

To effect reduction, in most cases in which no strangulation has taken place, it is only necessary to place the patient in the horizontal position, when the hernia will generally slip up spontaneously. If not, a gentle application of the taxis will secure this end, after which a neatly-fitting truss, to be worn constantly in the day-time, will keep it from descending.

In infants, the constant application of a truss day and night will effect a complete cure within a year in the majority of instances of inguinal hernia. No infant is too young for a truss. The moment the hernia is recognised an accurately-fitting truss should be provided, and it is well to have it made waterproof, as the ordinary leather pad soon becomes soaked with urine, and irritates the skin. It will be well, however, to continue the use of the truss for another year. In adults, however, the truss must be worn for very long periods, and generally for the remainder of life.

Of the varieties of trusses there is practically no end. Any instrument which fits comfortably, and effectually prevents the descent of the bowel, without producing pain or chafing of the skin, and which does not interfere with the free movements of the body, may be regarded as safe. As a rule, the pad should not be of such a shape as will ultimately lead to enlargement of the original opening. This is of much importance in the treatment of infantile hernia. The instrument, in the case of adults, may be removed, after retiring to rest, but it should be adjusted before the patient resumes the vertical position. Where the means and opportunities of the patient permit, it will be well to have an instrument specially made and fitted by an experienced instrument-maker. The cheap, ready-made trusses are often a source of much trouble and annoyance. It is advisable for the patient to have two instruments. In case of any accident or mishap the reserve truss may be used. Fatal results have often occurred whilst the patient has been going about without support during the period that his truss has been under repair.

The measurement for a truss for inguinal or femoral hernia may be made by passing a tape line round the pelvis, less than

one inch below the iliac crests, the ends meeting at the hernial orifice.

The utmost cleanliness should be observed, especially in young subjects, and the skin under the pad may be frequently dusted with French Chalk or Oxide of Zinc. A very common mistake is made in forgetting that, owing to the rapid growth of the body in very young subjects, the truss soon becomes too small.

The writer has observed almost complete arrest of development of the testicles from the *continuous* use of tight-fitting trusses—a result which he does not remember to have seen noticed by surgical writers.

Irreducible hernia will require considerable modifications in the shape, form, size, and consistency of the pad suitable to the requirements of different cases. A bag-truss will be necessary for large tumours, while small ones may be treated by a small hollow pad.

Umbilical hernia must be retained in position by a suitable concave circular pad. As these herniæ are very often irreducible, the best method for their treatment will consist in the adjustment of a neatly-fitting abdominal belt, constructed so as to protect and support the prolapsed intestine. In the case of the very common infantile form, a flattish, firm, leather pin-cushion of circular form, without much convexity, and many times larger than the opening, should be placed inside the roller, and kept firmly bandaged over the umbilicus. The insertion of convex, button-shaped pads are to be condemned, as they tend to keep the aperture from contracting. Often a few strips of strapping passed across the opening are sufficient to keep it closed.

When a hernia showing signs of strangulation comes before the surgeon, prompt measures must be immediately undertaken for its relief. It may be down but a few hours when dangerous constriction may have already set in. *Recent* herniæ of any variety, and *femoral* hernia especially, are very dangerous. Old herniæ are not so rapidly fatal, but under no circumstances is time to be lost in dealing with a strangulated hernia.

The bowel must be returned within the abdomen by the taxis, or, failing this, by the operation of herniotomy.

The taxis, with the gentlest pressure, will often be found to speedily reduce the hernia if found soon after its descent, but when symptoms of strangulation have set in for any length of time the taxis is too often a failure. It should be tried in all recent cases, but the utmost gentleness should be maintained. When a hernia has been discovered in a patient suffering from strangulation for several days, the first touch of the surgeon's fingers upon the tumour will convince him that manipulation means further injury of the patient's chances of recovery. Pages might be written upon the dangers of the taxis. Most surgeons are loud in their condemnation of it, and some go so far as to say it should not be attempted except under chloroform, and then

only for a few seconds. No rule or rules can be laid down to guide the student in the correct appreciation of how far he is justified in persevering in his attempts to force the knuckle of bowel or omentum back into the abdomen. The conscientious attendant must be left to his own judgment of how far he is justified in persisting in manipulation before seeking the aid of an experienced surgeon.

Unfortunately an unworthy motive may creep in at this time, and though it is not a pleasant duty to dwell upon the petty weaknesses of our nature, nevertheless it is right that the young practitioner should be placed upon his guard against himself.

He may feel that in calling in a surgeon who might probably reduce the tumour at once he may lose the confidence of his patient and of those around him. This sometimes tempts him to prolong his efforts at the taxis till serious damage is done to the contents of the sac.

It is much better to take the patient into his confidence, explain the exact situation and its dangers, and seek the aid of an expert without loss of time. In hospital cases it has been often the experience of the writer to find that the taxis has had an exhaustive trial at the hands of several industrious performers before admission. In such cases it is sometimes wonderful to see how little injury has been inflicted upon the bowel, and one is at times forced to conclude that too much has been made out of the dangers of prolonged trial of the taxis, though doubtless the nutrition and circulation of the constricted parts in these instances may have been seriously interfered with.

To apply the taxis the patient should be placed upon his back, with his shoulders raised and the thigh partially flexed and rotated inwards, so as to cause as much relaxation as possible of the tissues in the neighbourhood of the neck of the sac.

The surgeon lightly grasps the neck of the sac between his left thumb and forefinger, and when all is steadied, with all the fingers and the thumb of the right hand he seizes the tumour, and attempts, by a combination of a pulling down movement and squeezing, to expel the liquid and gaseous contents of the sac, and secure its return. It is advisable, as just said, to make traction downwards at first before an attempt is commenced at pushing up the tumour. The pressure should be very moderate and even, and accompanied with a slight kneading movement. The degree of force applied (always slight) should be exceedingly gentle in cases where the hernia has been long prolapsed. Where the symptoms are very acute from the moment the hernia has descended, or where there is evidence that the sac is inflamed or that the gut is gangrenous, the taxis should not be attempted.

After gentle pressure for some time the operator may have the satisfaction of feeling the hernia suddenly slip up with a jerk and gurgle. If he has used no force he may feel confident

that all is well, but if considerable pressure was being employed at the moment of the ascent of the tumour he may reasonably fear that the hernia has been returned *en masse*, or that rupture has occurred. Omentum goes up gradually and without noise.

Erichsen recommends that when the taxis fails, if the patient be thin, and the aperture through which the hernia has escaped be well defined, the finger nail may be inserted, and the margin of the aperture may be pulled or pushed firmly to one side whilst a renewed attempt at the taxis is made. Wherry recommends that the patient should be directed to cough during the trial of the taxis. A large enema may with advantage be given.

When the taxis fails after a moderate trial, the patient may be put to bed, and before deciding upon herniotomy the effect of cold upon the tumour may be tried. Where the strangulation is very acute, or where the bowel has been prolapsed for days, or where there is evidence of gangrene or inflammation, or where the hernia is known to have been irreducible before the symptoms of strangulation set in, no further delay should be permitted, but herniotomy should be at once resorted to. In recent cases, however, there is a reasonable hope that cold combined with the taxis may succeed where the latter has failed alone.

Ice may be applied to the tumour for 3 or 4 hours. Leiter's Tubes may be tried, or the intense cold produced by the ether spray apparatus may be utilised and the cold douche has been successful. These in recent cases have been known to effect reduction. They are valuable when the symptoms are not urgent and where vomiting is not severe, and in cases of delay in procuring an operator they are of great value if they only succeed in preventing continuous attempts at the taxis. A large dose of Opium (2 to 3 grains, or a hypodermic of Morphia may be given under such circumstances with advantage.

Hot baths are doubtless of much value where a large bath can be brought alongside the patient's bed, but the usual practice of causing a patient who is suffering from strangulated hernia to walk down one or more flights of stairs to the bath-room is a serious danger.

The taxis with the body inverted, or the intestines inflated by enemata, and various other plans of this kind, should be discountenanced.

The practice of aspirating the contents of recent herniæ and then applying the taxis has found favour with several surgeons, and if a very fine hollow needle be used, there is little danger of extravasation. Thus, Hern has tapped the tumour with a hypodermic needle in 32 cases, with easy reduction in 28. In the remaining cases, after the tapping, the hernia was operated upon, and no traces of the punctures could be detected. It fulfils all he claims for it—viz., it avoids the delay almost inseparable from herniotomy, it lessens the evils of the taxis by diminishing the tension of the

tumour, and it very often does away with the necessity of the cutting operation, with its septic dangers.

Where the above-mentioned measures fail, the last final trial of the taxis is to be made under the influence of chloroform or ether. Before administering the anæsthetic, it should be finally decided that if the tumour cannot be reduced under a few minutes trial the surgeon should proceed with the operation of cutting down and relieving the strictured bowel without waiting for the patient to come from under the influence of the drug. Often reduction takes place easily under chloroform where the taxis has previously failed without its aid.

It sometimes becomes a serious question whether the surgeon is justified in operating, owing to the advanced state of collapse in cases where there has been great delay before coming under notice. The death of the patient being obviously inevitable without relief, he should always get the benefit of the doubt, and the operation should always be tried. It is surprising how the most unpromising cases sometimes recover. The writer has operated successfully in a case where a recent hernia had been down seven days.

The operation is not necessarily a very painful one, and where chloroform is not admissible, Cocaine injected over the tumour considerably relieves pain.

The writer has assisted Dr. J. W. Browne at a case where the patient, owing to a heart complication, decided to have herniotomy performed without an anæsthetic. She watched some of the stages of the operation with manifest interest, and exhibited little signs of uneasiness, though Cocaine was not used.

The hair should be shaved from the surface of the tumour, and the skin carefully sterilised. As the patient lies upon his back with the shoulders raised and the knees flexed, an incision should be made over the neck of the sac. Its extent will depend somewhat upon the size of the tumour. In femoral hernia it may be made in a vertical direction, internal to the crural opening, or in an oblique direction, somewhat parallel to Poupart's ligament. In inguinal hernia the incision may be best made in the direction of the canal. The most rigid antiseptic precautions are to be maintained throughout the different stages of the operation.

The tissues are to be carefully divided, each layer being incised separately till the sac is exposed. The free use of the director is an advantage, as the appearance and thickness of the different layers of tissue vary so widely in almost every case. Vessels should be tied as the operation proceeds.

The sac is now invariably opened, and the contents exposed and examined. If the contained gut or omentum is not gangrenous, the stricture is divided on a hernia director and the bowel pulled gently down so that the portion which has been most tightly nipped may be inspected. If this is satisfactory, reduction is at once effected.

The condition of the bowel is a serious consideration ; if found purple or almost black, but free from gangrene, though covered with lymph and ecchymosed, it may be safely returned.

In other words, if alive and unperforated or unruptured, it should be returned. When found to feel like wetted leather and devoid of its natural elasticity, and ashy in colour or fetid in smell, the surgeon knows that it is dead. If ruptured or perforated it is equally unfit for return. The best course, then, is to thoroughly define the exact extent of the mischief and resect the destroyed part.

The introduction of Murphy's button has been a distinct boon in these desperate cases, as it enables the resection to be carried out in a few minutes—a matter of the utmost importance where the patient is already profoundly collapsed, and quite unfit to bear the shock of a prolonged operation. A large number of successful cases have now been published in which the button has been used.

Some surgeons recommend that an artificial anus be established in preference to resection. This may be the only course open if the patient is unable to bear a protracted operation. Great care is taken not to interfere with adhesions, but to leave the gangrenous bowel *in situ* after incising it to permit the escape of faeces. Where only a small portion of the gut is involved it may be left *in situ* without being opened. A subsequent operation afterwards may be undertaken to cure the artificial anus.

The mistake generally made is to remove too little. It is essential to divide the bowel well above and below the gangrenous patch.

Omentum, if inflamed, gangrenous or adherent, may be removed without hesitation. In old-standing omental hernia it should never be returned, as it is likely to increase the intra-abdominal tension and bring about recurrence.

After reduction, some form of radical cure is now almost invariably attempted. The sac is freed from the cord right up to the internal abdominal ring, ligatured as high up as possible, and the neck, or neck and fundus, removed. The hernial orifice is then closed by three or four sutures of silk or catgut which unite the internal oblique and conjoint tendon to Poupart's ligament, the actual method depending on the choice of the individual, Bassini's operation, or some modification, being now the greatest favourite. All hæmorrhage having been carefully arrested, the skin wound is closed without drainage. Several layers of sterilised gauze dressings and absorbent wool are applied and kept in position by a firm spica bandage. As a rule, the dressings are not disturbed for a week, when the wound will be found to have united by first intention. *After treatment*—Opium is to be avoided except in rare cases where there is a doubt as to the condition of the returned gut. The bowels may be left to act as soon as nature wishes, which will generally be the second or third day. If

necessary an enema of warm water and olive oil may be employed on the fourth or fifth day. Purgatives should as a rule be avoided.

Inflamed hernia.—The cause should be remedied, the irritation of a truss often being the factor in a hernia which is not reducible. The taxis may be the cause, hence any attempt to reduce a hernia, the seat of inflammation, should be avoided. Rest in bed, with the application of cold to the tumour, is generally all that is required. The best method is to apply Leiter's tubes over the hernia or to use an ice-bag. Pain should be relieved by Opium, which is also necessary to secure absolute rest to the bowel. The diet should be restricted to beef-tea or iced milk.

Radical cure of hernia is now constantly undertaken, and the operation is one of the safest of surgical procedures. Thus M'Ardle, of Dublin, has operated 406 times with only two deaths. Barker records 200 consecutive operations with three deaths, one of which was from chloroform and one from diabetic coma, the diabetes having been present before operating. Bull and Coley have collected 1,000 cases with a mortality of 0.9 per cent.

[The operation selected will depend on the surgeon's taste, and each operator soon comes to adopt some minor modification of his own. The safety which has followed in the track of aseptic surgery has effectually banished the older methods which were designed to avoid cutting, and some form of open operation is now always employed. The methods of Bassini, Kocher, Ball, MacEwen, all have their advocates. I do not hesitate to recommend the former, having performed it about 50 times without a death, and so far as I know without a recurrence, on patients aged 9 months—40 years.—A. B. M.]

The operation is indicated—

- (1) In healthy children, where a truss has failed to cure the hernia after three years.
- (2) Where a suitable truss cannot be obtained, or the parents, as frequently happens in hospital cases, fail to renew the truss at regular intervals.
- (3) For acquired hernia in healthy adults.
- (4) For young women who generally dislike the idea of a truss.

As a formal proceeding it is not advisable in acquired hernia coming on after middle life, where the muscles are beginning to atrophy. In such patients, as Lockwood has pointed out, the condition is likely to recur, and a well-fitting truss is all that is required.

For the details of the operation and its modifications, the reader is referred to works on surgery.

Recently excellent results have been obtained in the treatment of infantile herniæ, both umbilical and inguinal, by the injection of Artificial Serum beneath the skin, about the periphery of the hernial opening. 15 minims of a solution of Phosphate of Soda 5.

Sulphate of Soda 10, water 100, are injected with the view of producing a mild inflammation, which causes closing of the sac.

HERPES.

For the most part, herpes præputialis, herpes labialis, and herpes iris are trivial and short-lived troubles which require no treatment. Occasionally a mild local sedative may be applied, and, owing to the common site of these eruptions—viz., on the face, lips, or hands—powdery preparations are inconvenient. An ointment like the following answers all purposes.—

R. *Calamina Præp.* ʒij
 Liquor. Plumbi Fort. ʒss.
 Unguent. Zinci Oxid. ʒiiss. misce.

Fiat Unguentum.

The vesicles may be painted over with *Flexile Collodion* where an ointment is not convenient.

In some cases of herpes præputialis, with a long foreskin, powders are especially useful.

Herpes Zona, or shingles, is sometimes a very painful affection. Mild cases require little treatment except local applications, to prevent injury and friction to the vesicles till they spontaneously wither up.

A piece of lint or soft linen, smeared over with the above ointment, laid upon the seat of the eruption and covered with a pad of soft absorbent wool, fastened with a light bandage, is a simple routine plan, meeting all the requirements in most cases. Where pain is severe, Cocaine may be added to the ointment, or Cocaine or Morphia can be mixed with Collodion, and painted over the vesicles. Where the situation of the eruption permits, powders are better. The parts may be well dusted with powdered Starch, Oxide of Zinc, Calamine, Bismuth, Calomel, Lycopodium, Fuller's Earth, Talc, &c.

Acute neuralgic pain may demand anodynes by the mouth, or Morphia hypodermically, and should the vesicles burst or get rubbed, the smarting may be relieved by lotions containing Lead and Opium. Many writers testify to the remarkable power exercised by small (1/10 gr.) and frequent doses of Phosphide of Zinc in diminishing pain and cutting short the eruption. Antipyrine often gives marked relief. With the view of aborting the attack, Unna paints the affected region over with a paste made by rubbing Ichthyol with water, or by applying a gelatin paste containing Zinc and Resorcin. The continuous or interrupted current has been used with the same intention, the electrodes being placed over the course of the affected nerve.

With the view of aborting the eruption, Dupas soaks absorbent wool in 90 per cent. Alcohol, lays it upon the seat of the developing

eruption, and covers it with oiled silk. A 2 per cent alcoholic solution of Resorcin, or of Tannin, or of Menthol or Thymol, acts even more rapidly. Thiol, in 30 per cent. aqueous solution, has also been found very efficacious. Head says that in spite of many statements to the contrary, no treatment is effectual in aborting the eruption.

The neuralgia sometimes following the attack may be treated with Quinine, Salicylates, Antipyrine, Arsenic, &c. The writer has seen Colchicum prove useful, as recommended by Fagge. He has had good results from the continuous current. Nerve stretching, nerve section, or resection may be performed for old-standing neuralgic pain.

Where the eruption appears in the course of the ophthalmic division of the fifth nerve the severe pain must be relieved by narcotics or Antipyrine. Cocaine may be dropped in solution into the eye, and the lids covered with a piece of lint, smeared with an ointment of Calomel (15 grs. to 1 oz), and the eye bandaged over with a large pad of boracic wool. The greatest care must be exercised in preventing the accompanying conjunctivitis and keratitis from causing ulceration and perforation.

The writer has had a severe case of herpes zoster in a patient who was taking large doses of arsenic for chorea, and this cause, first pointed out by Hutchinson, should not escape the attention of the physician.

HICCOUGH.

The cause, when possible, should be removed, and, as this may be found in the stomach, a smart emetic may stop this troublesome symptom. A teaspoonful of Mustard in a tumblerful of warm water is a speedy and efficient agent for producing vomiting.

Sedatives to the gastric surface, as Morphia, Cocaine, and Chloral, may be tried, they often fail. Morphia hypodermically or Chloroform inhalation will sometimes remove the hiccough entirely. Nearly always temporary relief can be obtained from their use. Doses of narcotics sufficient to affect the respiratory centre may relieve speedily if not, their administration should be stopped, as they make matters worse.

Cannabis Indica, Opium, Hyoseyamine, Camphor, Oil of Amber, Magnesia, Musk, Vinegar, Bromide of Potassium, Bismuth, Antipyrine or Antifebrin, Belladonna, Ether, Nitroglycerin, hot Brandy Nitrite of Amyl, Iodoform, Creosote capsules, Turpentine, Ergol, Hydrocyanic Acid, Strychnine, Valerianate of Zinc, Pilocarpine (hypodermically) Ice, and many other remedies have been used successfully. Unfortunately the use of any remedy is purely empiric. What relieves or cures at one time will often fail utterly upon the next trial. A smart purge should be given when the symptom has continued for any time, and the various drugs in the above list may be tried in turn. The best results

appear to be obtainable from Pilocarpine hypodermically and small doses of Cocaine by the mouth.

Many methods have been advocated by which the nerve supply of the diaphragm may be influenced, either directly, reflexly, or by inhibition. Thus a sudden fright stops hiccough in children promptly, but though the writer has often proved this, there are serious objections to the use of this agent as a therapeutic remedy.

A less objectionable method of treating the affection is by directing the patient to take a deep inspiration or expiration, and to hold his breath as long as he possibly can. Raising the arms above the head, and keeping them there till the muscles tire, sometimes stops it. Counter-irritation to the stomach, cervical spines, or over the phrenic nerve may succeed. Pressure over the nerve in the region of the scalenus anticus sometimes stops it instantly, and firm pressure upon the supra-orbital nerve for one or two minutes often acts in the same way. Firm depression of the tongue may be successful. The most recent success in treating persistent hiccough is reported from the application of Laborde's method—i.e., making forcible traction upon the tongue for about two minutes. Noir reports two bad cases successfully treated in this way. Sneezing may be induced by Snuff or Ammonia, and may cause the hiccough to cease. Washing out of the stomach has been resorted to with success after failure of all other agents.

Cold applied to the lobe of the ear or to the external meatus has been found successful, and Cocaine may act in a similar way.

Galvanism seldom does any good, but a smart shock sometimes speedily relieves, probably by its moral effect. A cold shower bath may act in the same way. These latter agents are especially valuable in hysterical cases.

HIP JOINT DISEASE.

The chief indication at the beginning of this serious ailment is to prevent all inter-articular pressure, and secure absolute fixation of the diseased joint. The patient should be put to bed upon a hard, unyielding hair mattress with his head comfortably raised, but with the shoulders in the same plane as the body. He should lie upon his back, and extension by means of the weight and pulley should be brought to bear upon the affected limb. This is easily done by attaching a stirrup to the limb by means of plaster, applied to the lower half of the thigh. To the stirrup a cord is attached which passes over a pulley, and to its end a weight of 2 to 6 lbs. is attached. Traction by this means is to be made in the direction which the limb has assumed as the result of the disease, and the deformity gradually corrected. This treatment is to be kept up till all deformity disappears, and till pain and tenderness about the joint are no longer felt. It is the best of all methods of dealing with acute cases, or with those examples of the disease associated with much pain or spasms of the muscles. Where considerable deformity has already occurred without ankylosis,

and it is highly desirable that this should not occur in a position which might seriously interfere with the use of the limb, the deformity should be removed before beginning extension.

With this object in view the patient should be chloroformed and the deformity partially remedied. The utmost caution and gentleness being essential in order to avoid setting up further mischief in the joint, it is wiser not to insist upon the deformity being entirely remedied by manipulation. The extension by pulley and weight will complete what force has already partly accomplished under chloroform.

Unless the deformity be long established or severe, chloroform and manipulation will not be required. The weight and pulley if skilfully adapted, will reduce most angular positions in a few weeks, and it will be wise to give extension a trial before resorting to what may end in exciting further mischief in the joint.

Marsh lays stress upon the importance of applying the extending force in the direction of the axis of the deformity, otherwise inter-articular pressure is not diminished.

Abduction is best corrected by applying the weight and pulley to the affected side as just described. After a few days a long splint may be adjusted to the sound limb. This is, moreover, advisable in all cases, as it prevents the patient moving or sitting up.

Where marked adduction is present the deformity must be corrected. This is done by treating the affected limb with weight and pulley in the ordinary way. The sound limb is then bandaged to a long splint, from the inferior end of which a cord is led along the outside of the splint to a pulley fastened at the top of the bedstead by fixing a weight to the free end of the cord. The extending forces are applied to the different limbs in opposite directions and adduction is minimised.

As soon as possible the patient should be put into a Thomas's splint, with a high-heeled boot on the sound foot, and allowed into the open air upon crutches. If the affection is at a standstill during the winter, bed is the best place for him, and the extension by weight and pulley may be kept up for a long period, but in summer Thomas's splint may be applied at an earlier period. It is of vital importance that time be not lost in these cases when the season admits of the patient getting out. Struma or tubercle is the cause of hip joint disease in the great majority of cases, and the appropriate treatment for this malady must be carefully carried out simultaneously with mechanical management. The advantages of change of air and scene and a sojourn at a sheltered sea-side spot, protected from the north and east, cannot be exaggerated, but the temperature should be equable, and the air as far as possible free from excessive moisture. All means to improve nutrition and raise the standard of health should be attended to, but as these are referred to under Scrofula they need not be here enumerated.

The splint should be worn both day and night as long as there are any symptoms of mischief. In young children the splint should be double. In this apparatus they can be easily carried out into the open air, and the evacuation of urine and faeces attended to with ease and comfort. Should pain or tenderness supervene, the splint must be removed and the patient placed upon his hard mattress with the pulley and weight, and kept there for a month after the acute symptoms have passed away. As Thomas's splint must be worn for a long period—perhaps two years—steps should be taken to counteract the evil consequences which are bound to follow its constant application. This can only be done, after local symptoms have disappeared, by the careful and judicious employment of gentle massage applied to the wasted and weakened muscles of the limb.

Notwithstanding the most rigorous application of rest, sometimes the case goes on to suppuration, and enormous abscesses may burrow in various directions and set up fatal exhaustion and hectic.

As soon as the abscess is detected an anæsthetic should be administered, a free incision made into the sac, the pus evacuated, and the thickened sac wall thoroughly removed by scraping with Barker's flushing curette. If diseased bone is present it is removed in the same way. The cavity is then plugged with gauze and pressure maintained for some time till hæmorrhage is arrested. The plug having been removed, the wound is then sutured without drainage, and firm pressure applied by means of soft wool and a spica bandage. Barker recommends the introduction of Iodoform Emulsion into the cavity before finally closing the wound. Where this treatment has been carried out with careful aseptic precautions primary union is obtained, and there is little shock and no subsequent rise of temperature. The limb is carefully fixed by a suitable splint.

The practice of opening and draining these abscesses is a mistake. The result is to introduce into a non-septic cavity the organisms of acute suppuration and to set up a sharp septic fever, which runs a long and often disastrous course.

There is still much difference of opinion regarding the propriety of resorting to the ordinary operation of excision of the hip. The writer, speaking from a limited experience and more from the standpoint of a physician, might summarise the objections in a sentence. In *advanced* cases the results are bad, in *early* cases they are often satisfactory, but to ensure these satisfactory results the operation, which is always a serious one, must be undertaken at a stage in which there would be still legitimate ground for expecting a better result from extension and rest.

Barker has recently given an interesting history of 41 cases of excision, or modified excision, in which he opened the joint by an anterior incision, and by use of the flushing curette, supplemented in some instances by the keyhole saw, removed all accessible

diseased bone and tubercular tissue, poured a small quantity of Iodoform Emulsion into the cavity, and closed the wound. The cases were advanced ones, and all ordinary methods had been tried without success. In all of them abscess had developed, and in all the bones were extensively diseased. All cases recovered from the operation, and of 22 which he was able to trace, 3 had died from various causes; the others were well. The cases covered a period of 22 years.

He strongly urges operation before the formation of sinuses, involving, as they inevitably do, septic infection of the diseased area. He, however, never operates in the early stages.

The recognition of the tubercular nature of hip joint disease of late years has led to more persistent advocacy of operative interference, and the various methods of treating local tubercular abscesses is fully described under Tuberculosis. The Dublin method of drilling the bone in the neighbourhood of the joint, washing out with carbolic lotion and securing absolute fixation, has given excellent results.

Where there is extensive disease of the head and upper end of the shaft of the femur with a similar condition of matters in the pelvic bone, the only course open is amputation. A case must be indeed very far advanced which justifies the surgeon in refusing to amputate. The aspect of the parts which at first sight is so unpromising may be the best reason to hope for a success in apparently hopeless cases. The pale gelatinous and strumous infiltration of all the tissues, riddled with sinuses, may be divided in some cases with surprisingly little hemorrhage and shock to the system. In 1872, the writer, with Doctor Newell, operated in an apparently hopeless case. The femur was found extensively diseased in its upper third, and was the seat of spontaneous fracture and there was advanced destruction of the ilium, ischium, and acetabulum. After all dead bone had been removed and a considerable portion of the pelvis gouged away, the vessels were discovered to be so diseased as not to bear a ligature, and it was found necessary to dissect up the femoral artery in the flap, and apply a ligature to the external iliac in the abdomen, which the writer accordingly did. Though the patient had suffered much from night sweats and hæmoptysis, she made an excellent recovery, and is still living and in robust health.

HIVES—See Erythema.

HOARSENESS.

The removal of the cause should be the first object; simple overstraining of the voice being a common cause of this condition, rest should, as far as possible, be insisted upon. The use of the following gargle relieves, and when some effort of the voice is

inevitable, either in singers or public speakers, it may tide them over an engagement.—

R. *Acidi Tannici* ℥i.
 Glycerini Boracis ℥ij.
 Tinct. Capsici ℥ss.
 Inf. Rosæ Acidi ad ℥x. *misce.*
Fiat gargarisma saepe utendum.

Where hoarseness results from or is symptomatic of a true inflammation of the larynx, the remedies suitable in laryngitis are to be used. Local laryngeal troubles, as small tumours or thickening of the cords, interfering with the closure of the rima, may be dealt with surgically. Syphilitic affections will probably disappear under Mercurials. Exudation, as in diphtheria, may only betray itself in hoarseness, and demands treatment of a prompt and serious character. (See Diphtheria.) Hoarseness, depending upon centric nerve lesions or the pressure of aneurismal growths causing partial paralysis of the adductors of one cord, will demand attention to the primary lesion.

(See also under the heading of Laryngitis for the treatment of the various conditions of which hoarseness is the chief symptom. See also under Throat.)

HODGKIN'S DISEASE—See Lymphadenoma.

HOOPING COUGH—See under Pertussis.

HYDATIDS.

Preventive measures are of first importance. The disease is the direct result of the introduction into the human alimentary canal of the eggs of the *tenia echinococcus*—a small tape worm infesting the dog and wolf. The human hydatid is the larval form of this parasite. The eggs find their way into the human stomach chiefly through drinking water. Hence the necessity, in districts where the parasite abounds, to look most closely to the filtration of water and the purity of food. The utmost scrupulousity should be observed as regards the personal cleanliness of all who come into close relations with dogs. This minute worm is also found in dogs in this country in vast numbers in the small intestines. As the mature worm does not exceed $\frac{1}{2}$ inch, it is easily seen how readily the invisible eggs, or the last joint of the worm which alone contains the developed sexual organs, may find entrance into the human stomach in water or on salads, &c.

Curative treatment must be surgical. The wild statements made about the efficacy of Kamala, Turpentine, Chloride of Sodium, &c., have been proved to be devoid of truth. No drug at present known can be expected to destroy the hydatid when given by the mouth.

The following surgical procedures have been advocated :—

Acupuncture, carried out by the introduction for ten minutes of a long fine needle into the cyst, is sometimes successful. When it is, according to Verco and Sterling it produces its effect by permitting the contents to escape into the neighbouring cavities and tissues, and hence, owing to the danger of a general parasitic invasion, it is condemned by them as reprehensible.

Electrolysis, which probably acts in a similar manner, is also to be condemned.

One fact has been proved, that if a minute quantity of the liquid contents of the cyst be drawn off with a very fine aspirator needle, the result may be the death of the parasite and the gradual shrinking or withering up of the tumour. Liver cysts have been successfully treated in this way, but syphoning should be preferred to aspiration, as the aspirating of these cysts, when embedded in any solid region, is apt to cause such traction upon their walls by suction as may lead to inflammation and suppuration. If the aspirator be used, all the contents should not be removed. Where a small cyst depends from the liver into the abdominal cavity, the removal of a portion or of the whole of the fluid contents by a long, very fine aspirator needle attached to Dieulafoy's instrument is often successful. The operator should be slow to repeat the tapping in case the cyst should soon fill again till a sufficient time has elapsed to show whether the hydatid still lives. In such cases it is very undesirable to run any risk of suppuration, and time may prove that the operation has fulfilled its object, and further waiting may show the gradual withering of the tumour.

Where a movable cyst of moderate or large size hangs very freely into the abdomen, it was formerly considered safer practice to establish adhesions between the walls of the abdomen and cyst before tapping. This can be done in any of the ways in which ovarian cysts were formerly treated. Should the hydatid, however, be freely movable, the method of inserting a number of hare-lip pins through the abdominal wall into the cyst, and leaving them there for 12 hours, may be employed. After the withdrawal of the pins, the cyst, if a medium one may be tapped with a fine needle, and if of large dimensions a wide trochar may be plunged into it and the cavity washed out daily with antiseptic solutions to get rid of the daughter-cysts in its interior.

Very large hydatids are now removed by performing abdominal section, and in this direction surgical progress is rapidly marching. The modern practice is altogether in favour of radical cutting operations.

The surgeon, after removing the fluid contents, incises the cyst walls and stitches their divided edges to the edges of the incision in the abdominal parietes, without taking any means for insuring previous adhesion between the cyst wall and abdominal wall before operating. This, under the name of Lindemann's operation, is the usual procedure in Australia, where the disease is so common.

After stitching, the cavity is allowed to drain externally. Bond, however, after removal of the cyst contents and thoroughly washing its walls, drops it back into the abdominal cavity and closes the parietal wound as in ordinary ovariectomy.

Gardner, of Australasia, has successfully operated very frequently for hydatids, and he states that he has no hesitation in resecting ribs, opening the pleural cavity, incising the diaphragm, stitching the cyst to the diaphragm, and the diaphragm to the costal pleura and skin in all cases in which he finds cysts situated on the convex surface of the liver, a drainage tube being always inserted into the lowest part of the pleural cavity to provide drainage of any subsequent empyema.

Where suppuration has already occurred, the hydatid cyst may be treated as an ordinary abscess, and dealt with by free incision, by washing out with antiseptics, and by establishing drainage in abdominal cysts which have suppurated. The abdomen should be opened without delay, the cyst incised, its cavity washed out, drainage established, and its margins stitched to the abdominal wall.

The injection of various substances into the cyst, in ordinary cases, with the view of causing the death of the hydatid, has been advocated, and is still sometimes practised, but it is unnecessary, and liable to be followed by profuse suppuration. When the cyst is adherent and a large opening made, Iodine and other antiseptics may be employed to destroy smaller internal cysts too large to come through the opening, which should be kept patent by the insertion of a large India-rubber drainage tube.

Rudall recommends that tapping never should be performed till the surgeon is prepared to go on with the larger operation, and where suppuration is found to have occurred a large trochar and canula may be employed, and the latter should be left in for some days.

Ox Gall, Extract of Male Fern, and other anthelmintics should be abandoned, their injection into the tumour being certain to cause suppuration which the surgeon is anxious to avoid.

Hydatids in the lung or pleura can be successfully treated by excision of one, two, or three ribs, removal of the cyst contents and drainage. Aspiration is liable to cause death in pulmonary hydatid disease, and must not be resorted to. Should suppuration occur in the pleural cavity, a free incision must be made between the ribs, and the space washed out and drained as in empyema. Abscess of the lungs, if near the surface at the base, may in some cases be successfully treated in a similar way. Aspiration and subsequent injection of Carbolic or weak Perchloride Solution have given good results. Gardner performed thoracic section in 19 cases of lung hydatid, with only two deaths, and abdominal section in 47 liver cases, with five deaths.

Trephining for brain hydatids has been successfully performed.

HYDROCELE.

Chronic hydrocele of the tunica vaginalis is a common affection, and one frequently presented to the surgeon for treatment. If the collection of fluid is small and has remained stationary for any considerable period, it may be well to let it alone. When it has already reached dimensions, entailing inconvenience or pain, it should be tapped. This is done with a fine, sharp trochar and canula. Having placed the patient standing with his back against the wall of the room, the surgeon ascertains the exact position of the testicle in the tumour, after which he grasps the neck of the scrotum firmly between the thumb and fingers of the left hand and applies pressure, so as to render the hydrocele very tense. The trochar and canula having been boiled or left for a few minutes in strong carbolic lotion, should be held firmly in the right hand, with the tip of the index finger about two-thirds of an inch from its extremity, and plunged into the sac, avoiding the testicle. As the trochar is withdrawn, the canula is thrust home in the direction of the cord by depressing the hand. After the sac of the tunica vaginalis is thoroughly drained, the minute opening closes almost completely, if not, a strip of plaster applied over a bit of lint or gauze is all that is needed. Hospital patients generally immediately afterwards resume work, though this is to be forbidden. In their case it is better to tap the tumour after their day's work is over. In a small percentage of cases the hydrocele does not again form, but generally the fluid re-accumulates at a shorter interval after each tapping.

Many patients prefer to being relieved in this way when the fluid continues to accumulate slowly, but, especially in young subjects, the surgeon should recommend a radical operation. This is carried out after tapping, by injecting through the canula into the sac with a syringe possessing a long nozzle, one or two drachms of the B.P. Tincture of Iodine. After its injection, the scrotum may be kneaded between the finger and thumb, with the view of setting up further irritation by the manipulation. Any excess of iodine is then allowed to escape and the canula removed.

Different operators have their favourite injections, some even prefer to draw off the injection through the canula before withdrawing it. The Tincture of Iodine may be diluted with an equal quantity of water. A good solution is the following (the whole may be injected):—

R. *Iodi Purif.* gr. i.
Potassi Iodidi gr. viii.
Aque Destil. ℥iv. *misce.*

Care should be exercised in the injecting or drawing off of the liquid (when this is done) to prevent the escape of any into the cellular tissue outside the sac.

Tincture of Iron, Port Wine, Chloride of Zinc, Perchloride of Mercury solution, or a few grains of Red Precipitate or Iodoform, and many other irritating substances are used, but the above answer most purposes. It is necessary that every drop of the hydrocele fluid should be first evacuated, and that the manipulation should afterwards insure that the injection be made to come into contact with all parts of the sac. The patient should be sent to bed for a day or two, as sometimes the inflammation excited by the irritant sets up considerable local pain and uneasiness, though in some successful cases neither pain nor uneasiness may be experienced throughout.

Excellent results have been obtained by injecting from 5 to 10 mins. of pure Carbolic Acid, and some surgeons permit the patient to immediately resume his work after the injection. It causes little pain.

In one case in which the writer used the carbolic acid injection the sac became suddenly tympanic, but there was no other untoward result, and the cure was complete, without pain or distress of any kind. It was not possible to see how air had been admitted. The hydrocele was an old one, and had frequently been tapped before.

If a weak solution of Cocaine be injected before the irritant, a practically painless operation may be performed after its removal.

In some cases failure results, the fluid which is secreted after the injection does not become absorbed, and the case returns to its old condition. A second or a third trial may be made by injections, each time using a stronger solution, and, if these fail, the following means should be employed —

Incision of the tunica vaginalis is made for about 2 inches by cutting with a sharp scalpel vertically into the front of the tumour. After tying all vessels and washing out the cavity with antiseptics, a drainage tube is to be left in and the edges of the incised tunica are to be sutured to the margins of the skin wound, and the scrotum dressed antiseptically.

This method has the objection that it involves a convalescence of 2-3 weeks, during which frequent and somewhat painful dressings have to be carried out. It is much better to remove the entire sac. An incision is made in the scrotum down to the sac without opening it, by the finger or a blunt director the loose scrotal tissue is rapidly and easily separated from the tense sac, and the hydrocele and testicle dislocated into the wound. The cyst is next freely incised and the serous contents allowed to escape. The sac wall is then removed by scissors close to the epididymis, the testicle returned, any bleeding points ligatured, and the scrotal wound closed without drainage. A single dressing usually suffices. The sutures are removed at the end of a week, and the cure is complete.

In children this method is preferable to injection, as it is completed under the anæsthetic and involves no subsequent pain or interference.

Buschke drives a trochar into the lower portion of the sac, washes it out with Carbolic lotion, brings the trochar out at the upper part and introduces a drainage tube with lateral openings which allows all liquid to ooze into antiseptic gauze. He removes the tube in 5 days, and healing is generally complete in a fortnight.

Hydrocele in infants or young children may be treated by acupuncture when iodine applications or cooling or astringent lotions fail to cause absorption of the fluid in the closed sac of the tunica vaginalis.

A glover's needle or hare-lip pin is thrust into the sac through the skin over the hydrocele, and without withdrawing it through the skin wound it is several times withdrawn from the sac and pushed in again in different places. In this way the fluid from the hydrocele passes into the cellular tissue of the scrotum and is absorbed, and the case often ends in a radical cure. Where this measure fails, tapping and injections must be resorted to.

Acupuncture may be used with success in those cases where the hydrocele in infants extends for a variable degree along the front of the cord without any communication with the interior of the peritoneal cavity. It should always be resorted to before injecting with Iodine or Carbolic Acid.

Congenital hydrocele requires different management from the varieties just mentioned. In it there is an uninterrupted water way between the cavity of the peritoneum and the tunica vaginalis. Here the first object should be to prevent the descent of a hernia through the patent canal, and at the same time to take steps to hasten the closure of the congenital opening. Both these objects are attained by gradually forcing all the fluid back into the peritoneal cavity, and applying an accurately fitting truss to be worn day and night till sealing up of the opening is effected. Afterwards any accumulation of fluid still in the tunica may be treated by acupuncture or injection. Where these means fail, especially if hernia co-exists, a radical operation for the closure of the neck of the sac may be undertaken.

Encysted hydrocele of the cord or testicle, when of such dimensions as to cause inconvenience or pain may be treated exactly as if an ordinary chronic hydrocele of the tunica vaginalis. It may be tapped, and should the fluid continue to reaccumulate after successive tapings, Iodine, Carbolic Acid, or other irritating liquid may be injected, and should failure still follow, an incision may be made and the cavity drained and dressed antiseptically.

HYDROCEPHALUS, Acute—See Meningitis.

HYDROCEPHALUS, Chronic.

The treatment of this malady can only be palliative. Everything should be tried which can be expected to improve the faulty nutrition upon which the diseased condition is probably

depending. In those cases where the accumulation of fluid is believed to be caused by the pressure of tubercular growths, the various means by which the straining condition can be improved may be employed. (See *Scrofula*.) It has been stated that hydrocephalus is occasionally the result of congenital syphilis, and that it may yield to Mercurials.

Where the condition supervenes upon the acute affection, or where it is supposed to be owing to an idiopathic dropsy, counter-irritation of the scalp by Iodine or Cantharides has been recommended, but little is, however, to be expected from this treatment. In very young subjects the careful inunction of Mercurial Ointment has given some decidedly satisfactory results. It cannot, however, be pushed far without doing harm. Iodides internally, in combination with Bromides, afford the best chance of improvement. The writer believes that there is no means by which the nutrition of the body can be so rapidly improved as by the inunction of Cod Liver Oil in the way described under the heading of Mesenteric Glands. It should always have a chance in such cases as these under consideration. It may be rubbed into the scalp, and cloths saturated with the oil may be worn under a waterproof cap. Strapping of the head to prevent increase in size appears to be dangerous practice, though sometimes good results have followed the pressure of an elastic bandage worn for a considerable time over the scalp. Purgatives, Diuretics, or forced abstinence from liquids with a view to diminish the vascular tension, and thus reduce the accumulated dropsy in the ventricles, afford no prospect of success.

Iodine solutions have been heroically injected into the ventricles without producing evident good or evil.

The operation of tapping the ventricles and applying a rubber bandage has been several times performed, but with unsatisfactory results. An aspirator needle is pushed through the anterior fontanelle, avoiding the middle line till the ventricle is reached. More hopeful results have been obtained by trephining behind and above the ear, inserting the needle, and afterwards establishing drainage of the ventricle. The subarachnoid space has been successfully drained through an opening in the occiput in acute hydrocephalus, and success has occasionally followed puncture of the subarachnoid space of the cord in the lumbar region.

Recently Cheyne has permanently drained the lateral ventricles into the subdural space by making an opening through the cortex so as to lead to the absorption of the fluid by the villi of the arachnoid.

HYDRONEPHROSIS.

Where the cause can be traced to the blocking up of the ureter by a calculus, the first duty of the physician should be to immediately set about putting the patient in the most favourable

condition to prevent the formation of another calculus in the sound kidney. (See under Stone in the Kidney.)

Where the tumour is not already very tense nor of long duration, the simple operation of manipulating it through the abdominal walls should have a fair trial. With the anatomical position of the kidney and ureter, and their relations to other organs in the abdomen before the physician's mind, he may try a series of massage and pressure movements with the view of dislodging the calculus, or causing the fluid to flow past it into the bladder. This succeeded in one case in the hands of Sir W. Roberts, and the writer once believed that he caused a partial reduction in the size of a hydronephrosis after a prolonged examination, during which the tumour was submitted to a good deal of manipulation. This manœuvre is worthy of a trial, and before commencing it the patient's abdomen should be freely poulticed or swathed in warm water bandages covered by a piece of stout mackintosh for 48 hours—a local hot pack. It is needless to say that undue force should not be employed. Aspiration or tapping must be resorted to when the tumour is tense and of large dimensions. The site of the puncture is of importance. The sac should be entered from behind, midway between the last rib and the iliac crest, two and a half inches behind the anterior superior spinous process on the right side. On the left side the best spot is one just in front of the interval between the last two floating ribs (Roberts). All the fluid should be removed through a moderately fine and long needle. Three results are within the reach of possibility—(1) The fluid may not again accumulate owing to the previous destruction of the entire secreting structure of the kidney; (2) the tapping may, by relieving or removing the pressure and irritation, cause the descent of an impacted calculus into the bladder, or (3) it may be followed by subsequent discharge of hydronephrotic fluid into the bladder without the descent of any obstruction. These results, though very improbable, have been recorded in isolated instances, and justify the operation of tapping before resorting to more severe and dangerous measures. Aspiration may be repeated as often as the urgency of the symptoms demand, and in most instances is the only available means of relieving the distress and prolonging the life of the patient.

Of other measures the operation of establishing a free drainage of the sac, or of establishing a permanent fistula, is dangerous and should be abandoned. Rovsing has collected 12 cases with 9 deaths.

The kidney may be exposed by an incision 3-4 inches long, parallel to the last rib. In a few cases it may be possible to remove the obstruction through an incision in the sac, or the ureter may be incised over the stone if it can be felt.

Should the obstruction be due to torsion dependent on movable kidney, the organ must be fixed in its position, this

operation being known as nephropexy. In the majority of cases, however, operation will have been undertaken as a last resort after long trial of palliative measures, and the kidney will be found to be practically destroyed, merely forming portion of the cyst wall. There is no hope of restoring the function of such an organ. The other kidney has adapted itself to the altered state of affairs. The best and safest procedure is to perform nephrectomy.

Rovsing has collected 52 nephrectomies under such circumstances with 8 deaths, whilst 28 cases of incision and drainage yielded 13 deaths.

Some of Morris's reports show that the kidney in these cases with the dilated sac can be as easily extracted as an ovarian cyst which has but few and recent adhesions. He ligatures the pedicle by surrounding the renal artery first, and afterwards the renal vein and ureter by kangaroo tendon ligatures.

A case of hydronephrosis has been reported where rest in bed, with elevation of the pelvis by pillows, was followed by the evacuation of the contents of the tumour through the urethra.

Landau has published a series of cases where the hydronephrosis was intermittent owing to the occlusion of the ureter by torsion or tension in patients with movable kidney. In these cases, position with manipulation or external pressure for the most part succeeded in hastening the evacuation of the retained secretion, though some of his cases resisted these measures and ended in suppuration.

Goodhart has published two typical cases of hydronephrosis which had spontaneously recovered, and he reasons that many patients would recover if let alone.

Where hydronephrosis is a concomitant of ptosis of the liver it will disappear in most cases after fixation of the liver and kidney in their normal positions by sutures.

HYDROPHOBIA.

The preventive treatment of rabies is a very important subject. The disease is never spontaneous. Always arising from the introduction of a virus communicated to man by the bites generally of rabid dogs, the spread of the malady may be prevented by measures tending to check its transmission amongst the members of the canine tribe.

A universal muzzling law is expected to do much in this direction. A universal knowledge of the earliest symptoms of canine rabies will do more. Universal protective inoculation of dogs will achieve everything. A bite or wound inflicted upon man by a rabid animal should receive the promptest treatment. A temporary ligature when possible should be applied to the limb above the bite, and the most thorough cleansing of the wound effected. Doubtless many lives have been saved by sucking the injured spots with the lips immediately after the wound has been

inflicted. This procedure cannot be said to be absolutely free from danger, though the risk may be regarded as infinitesimal.

After application of the lips, the mouth should be carefully washed out and a free expectoration encouraged. The lacerated tissues should then be subjected to free and deep cauterisation. Nitrate of Silver, though considered by Roux as the least reliable, is the most convenient—in its absence the actual cautery should be used without delay. Strong Carbolic Acid is equally potent and much less painful. Fuming Nitric Acid freely applied is probably the best of all caustics. The bitten or lacerated tissues may be excised with the knife, and when this can be done immediately, it will be the most powerful of all measures in preventing after consequences.

Probably of all wounds thus promptly treated a very small percentage would be followed by rabies (possibly not 5 per cent.). This treatment, however, to be useful must be carried out without a moment's delay. As a matter of fact more or less delay almost invariably occurs and sometimes no attention is paid to the wound owing to the virulence of the animal not being suspected at the time. In any case, even prompt cauterisation of the wound should not interfere with the adoption of further measures, nor should the thought of future inoculative treatment prevent cauterisation at the time. Local treatment of the wound, judiciously carried out, must always minimise the danger.

The wound being inflicted, and the animal being reasonably suspected or known to be rabid, or proved afterwards to be rabid, the important question comes up: Should the patient take his chance of escaping the after consequences? The answer must in all cases be in the negative. This is obvious when the risks are considered. According to Ruffer, at least one person in every seven persons bitten by animals believed to be rabid perish from rabies if not treated by the Pasteurian methods. Of bites upon the face three or four out of five die, and wolf bites upon the face are still more fatal. Many authorities give much greater mortalities.

After Pasteur's treatment of *all* cases bitten by animals certified or *proved* to be rabid, excluding those dying during treatment and those dying within fourteen days after treatment had been concluded (i.e., before the inoculation could have had any effect), the mortality has now (1901) fallen to about 1 in 400. Up to the end of the year 1900, 24,065 cases had been treated at the Pasteur Institute at Paris, and of these only 107 had died. At the lowest probable calculation 1 in 7 of these would have died if untreated, the total saving of life is therefore at least about 3,500. But it is obviously far greater since these figures include face and head bites, 4 out of every 5 of which die if untreated.

Even if we take the first decade and include *all* the cases, those dying during and after treatment, it will be found that the total mortality falls far under 1 per cent. These startling figures are

eclipsed by those arrived at from an analysis of the face and head bites received from rabid wolves which are almost invariably fatal.

The mortality rises with every delay in the patient presenting himself for treatment, but since the incubation of hydrophobia varies so greatly—i.e., from two weeks in the earliest recorded case to two years or even more in some doubtful cases—it is hard to say when the prospect of treatment would appear to be hopeless. Pasteur informed the writer in 1891 that on studying his atlas he found the mortality to rise with the distance which the patient had to travel from the country in which he was bitten to the Institute in Paris, being very high in those foreigners whose home was at a distance and in those whose railway facilities were very deficient.

The virus producing rabies is believed to contain a living organism which has not yet been isolated or cultivated, unless we accept the organism of Bruschiellini or the microbe described by Spinelli and Revolto, and recently successfully cultivated by Memmo. Bacteria during their life produce chemical substances which ultimately check or inhibit their action, as man secretes substances which if again finding their way in quantity into his organism would cause his death. Pasteur believed that this suicidal weakness of all bacteria affords the means by which their ravages may be checked. His theory was that by injecting the chemical substance into the system of any animal it may be protected from the bacteria which produces this substance. He also attached considerable importance to the action of the attenuated living virus, which is injected along with the chemical substance.

Pasteur had not been able to isolate the chemical substance which is secreted by the living germs of rabies, but by attenuating the virus he diminished the amount of the living organisms, and at the same time increased the amount of the protecting chemical substance. His first injections may be regarded, therefore, from a therapeutic point of view, as inoculations of this vaccinating or protecting chemical substance.

Roux has, however, laid stress upon the far greater protective influence of the inoculations of attenuated virus than of inoculation of the pure chemical substances secreted by the bacteria.

To prevent the manifestations of a bacterial disease, it would appear that the vaccinating substance should be introduced into the system before the inoculation of the living virus. Owing to the fortunate circumstance that the incubation of rabies in man is so tedious, there is left ample time for the rapid action of the vaccinating substance before the outbreak of the disease.

The first step in Pasteur's method is to obtain a definite, strong virus which will always produce death in a given fixed time when injected into an animal. This powerful virus is only obtained after many inoculations, and, when procured, its lethal action is singularly uniform. It is developed in the following manner.—A

rabbit is inoculated under the dura mater with the virus from a rabid dog, and an emulsion from the medulla of the victimised rabbit is injected into another rabbit, whose medulla is in turn used for the inoculation of a third, and so on. After each inoculation the resulting virus becomes stronger, and the incubation period shorter, till, as the virus gains in virulence, the period of incubation becomes fixed at six to seven days.

The virus of the dog must be made to pass through 100 rabbits before this uniform or fixed virus is obtained. It is then many times more powerful than the ordinary virus of a rabid dog, and stronger than the virus from a rabid wolf.

A rabbit being inoculated with this fixed virus, takes ill upon the sixth day, and dies upon the tenth day after inoculation. If the spinal cord of this animal is now removed and exposed in a sterilised jar or bottle to air deprived of moisture by the presence of caustic potash, and kept at a temperature of 77° F., it is found that every day produces a diminution in the power of its contained virus. An emulsion, made by rubbing up a portion of the cord before drying, causes rabies to appear in an inoculated animal in 6 days, and death supervenes in 10 days, as just stated. After drying the cord for 8 days, and inoculating with it, the animal so treated does not die till about the 25th day. After drying the cord for 14 days, no effects whatever follow its inoculation.

Pasteur's method of treating patients bitten upon the limbs or trunk by rabid animals is, as soon as they present themselves upon the first day, to inject an emulsion of a spinal cord, which has been dried for 14 days, and also an emulsion of a cord dried for 12 days. The emulsion is prepared by crushing about $\frac{1}{2}$ a cubic centimetre (=the volume of about $7\frac{1}{2}$ minims of water) of the rabbit's cord in about 30 minims of sterilised beef tea, and the injection is made under the skin of the abdomen.

Probably no living organism is contained in these injections, or in those administered upon the second day, only vaccinating substance being found in them in the opinion of Ruffer. The second day two injections are also made, one from a cord of 12 and another of 11 days drying.

Third day	Injections from cords dried during 10 and 9 days.
Fourth day	8 and 7 "
Fifth day	Two injections from a cord dried during 6 "
Sixth day	One injection " 5 "
Seventh day	" " 5 "
Eighth day	" " 4 "
Ninth day	" " 3 "
Tenth day	" " 3 "
Eleventh day	" " 3 "
Twelfth day	" " 4 "
Thirteenth day	" " 4 "
Fourteenth day	" " 3 "
Fifteenth day	" " 3 "

Where the bites have occurred upon the face, or where the bites have been inflicted by wolves the above simple method has not been found to act with sufficient rapidity, as the incubation in face bites is very much shorter than in ordinary cases.

For these cases an *intensive* method is employed, the injected matter being prepared from cords dried for much shorter periods, so that the patient gets during the first three days all the injections which he would have received in five days had his wound been in the leg or hand, and on the seventh day he receives 1 c.c. of a cord which has only been dried three days, and so on till the fourteenth day, when a new series is commenced again, and continued till the twenty-second morning.

It may be said that suppuration never occurs at the seat of injection. This is owing to the scrupulous care which the writer has personally witnessed in every department of the work done at the Pasteur Institute.

Serumtherapy, which has proved such a brilliant success in diphtheria, promises to take the place of Pasteurism in the future. The difference of the two plans of treatment may be realised by looking at them in the following simple way—Suppose we bleed a patient who has just completed a course of Pasteur injections, it will be found that his blood serum is charged with a protective agent which, if administered to another subject recently bitten by a rabid animal, will prevent effectually the manifestations of hydrophobia appearing. This experiment, as far as the writer knows, has never been actually carried out, but it is almost certain that it would prove successful from the researches of Tizzoni and Centanni. These observers have injected into sheep large quantities of the virus of rabies after modifying its virulence by the action of pepsin. After 4 time the animals become immune to almost any dose of the living virus and their blood serum is found to contain the protective substance in such amounts as will, when injected into other animals, render them safe from lethal doses of the virus if administered a short time before or after the serum injections. The serum is perfectly harmless, and can be dried, and in this condition preserves its properties for long periods. They calculated that 38 grs. of their dried serum will be sufficient to protect a man ten stones weight if injected immediately after being bitten. They advise, however, that only half this quantity should be injected at first, the remainder being used afterwards. When an interval of 4 to 15 days after the bite has elapsed, twice the above dose is necessary.

Where the *symptoms of rabies* appear in a patient previously bitten by a rabid animal, treatment should be directed to the relief of the distressing symptoms. There are a few cases on record where the patient has been reported as cured, but most authorities regard these cases as doubtful. The result may be looked upon as fatal once unmistakable symptoms of the disease show themselves. Nevertheless, there are some agents which

should obtain a fair trial. The writer's experience is limited to two cases, which, it is needless to say, resisted all the remedies available.

The patient may be placed in bed in a very quiet and darkened room, and as few people as possible should be permitted to congregate about his bedside. Hypodermic injections of Morphia, or Opium and Chloral by the bowel, afford some measure of relief to the suffering when Chloroform or Ether inhalations cannot be tolerated.

Rapid mercurialisation by rubbing in the B.P. Ointment, or by the Mercurial vapour bath, has been tried, and was at one time considered as capable of destroying or eliminating the poison.

Every known narcotic has been unsuccessfully tried to prevent the spasms or convulsions. Nitrite of Amyl, Nitroglycerin, Calabar Bean, Aconite, Belladonna, Stramonium, Indian Hemp, Cold Affusions, Ice to the spine, Monobromide of Camphor, Arsenic, Bromides, Antipyrine, Cantharides, &c., have signally failed. Inhalation of Oxygen has been said to have been once successful. The best results may be hoped from Curare; if by its use the patient's life may be prolonged, there may be a faint hope that nutrient enemata, mild restraint, and perfect tranquility may keep him alive till the poison is eliminated. Curare should be given in large doses, $\frac{1}{4}$ to $\frac{1}{2}$ grain may be injected every 20 minutes till there are evident signs of general loss of muscular power.

Lucas Benham has published a series of cases of hydrophobia cured by large blood-lettings; and profuse sweating by means of Turkish or hot air baths is still maintained by a few enthusiasts to be curative. It may be tried in conjunction with Curare.

Tracheotomy may possibly be indicated in threatening death from laryngeal spasm.

HYDROTHORAX.

If this term be used to embrace the effusions of fibrino-serous liquid found in inflammatory conditions of the lining membrane of the chest, the reader will find their treatment mentioned under Pleurisy. If, however, by the term hydrothorax are meant those cases where the pleural cavity (generally both sides) contains more or less passive dropsical liquid, the treatment will be found under Bright's Disease.

HYPERIDROSIS—See Perspiration, Excessive.

HYPERMETROPIA.

As the blurring of vision in this condition arises from an error of refraction—the focus of entering parallel rays falling posterior to the retina—the condition in ordinary cases is easily remedied by suitable convex glasses, which neutralise the hypermetropia. Where the hypermetropia is severe it is best to correct it fully,

especially in children, with glasses which should be worn constantly. If strabismus is present, such glasses will remedy this complication, provided it be not constant. Where the squint is constant an operation will be required. In the case of older subjects, convex glasses of different strengths are required for near and distant vision.

HYPOCHONDRIASIS.

The severer forms of this affection passing into melancholia, where there are fixed delusive ideas which are entirely beyond the influence of reason or argument, can only be dealt with in most instances by removal from home surroundings for the facilities obtainable in a properly equipped asylum for the insane.

Even in the minor forms of hypochondriasis the treatment is most troublesome, and often most unsatisfactory. The physician having satisfied himself by thorough and painstaking examinations that there is no organic disease present, finds himself placed in a difficulty. If he obeys his instinct and proceeds to impress upon his patient the view that his symptoms are purely imaginary, and if he makes light of his suffering or painful sensations, he only aggravates matters by causing him still further to concentrate all his faculties upon his abnormal feelings. Upon the other hand, the physician may feel that to encourage the patient's consultations and to continue to accept his fees is to compromise his own sense of rectitude. It is perhaps for this latter reason that hypochondriacs are continually driven from one physician to another, much to their injury.

Though the treatment of these patients is most disagreeable, it is the duty of the humane physician to strive and relieve their distress as much as it is clearly his duty to minister to the sufferings of the lunatic or of the victim of hysteria, the disease in many mild instances being a true neurosis, differing from melancholia upon the one hand and hysteria upon the other.

Every departure from the highest standard of health must be carefully investigated. Dyspepsia, anæmia, constipation, gout, and other conditions when present are to be met by appropriate remedies.

Open-air exercise, especially if carried out in the company of others, boating, bathing, fishing, golf, or any active amusement in which the patient's mind is lifted off his everlasting sensations, will do more than physic. Travel, if the patient's means permit of it, if not, when possible, a complete change of employment may be advised. Resorting to hydropathies or places where invalids congregate often does harm. Occasionally, however, the patient returns somewhat improved, but with new combinations of sensations derived from comparing notes with his suffering brethren who flock about most health resorts. As a rule, anything which ensures a complete change of habits and of thought is likely to be followed by benefit. By taking and showing a real

interest in the sifting out of his symptoms, the physician should try and gain the confidence of the hypochondriac, after which his calm, firm assurance of the absence of any serious disease sometimes does much to dispel the patient's malady if in the early stages. Now and then one meets with instances of superior intellectual power amongst the victims of this disorder, and the writer has had successful results by taking such patients entirely into his confidence, and explaining to them the nature of the neurosis from which they suffer.

The worst cases, and those which tax the physician most severely, are those occurring in patients who exhibit a strain of insanity in their family histories; such can only be influenced by the tact, judgment, and devotion of their immediate friends. Any attempt to dispel the patient's fancies by directly reasoning him out of them generally ends in the physician losing his influence for good over the sufferer. This must be accomplished indirectly through his friends.

Should drugs be prescribed in cases of confirmed hypochondriasis? Though the answer is a difficult one, the writer does not hesitate to say that they should never be prescribed for the sake of humouring the patient in his whims. There are few patients who have long suffered from the disease who do not show some clear indication for constitutional or local treatment. When this can be conscientiously carried out by the physician, it may increase his power over the patient for good and prevent his falling into the hands of quacks and unscrupulous persons. Medicine should not be prescribed for the hypochondriac as a specific for his ailment in any case; it should always be considered as secondary in importance to the moral treatment. Of the host of drugs recommended, the writer has only seen decided benefit follow Arsenic, when given in small doses for lengthened periods. The following is a simple formula:—

R. *Liquor. Arsenicalis* min. xl.
 Tinct. Ferri Perchlor. ʒii.
 Tinct. Sumbul ʒvi.
 Aqua Camphora ad ʒiv. misc.

Fiat mistura. Cupiat ʒj. ter in die ex ʒii. aquæ post cibos.

Strychnine often aggravates, and there is a consensus of opinion that alcoholic stimulants and opiates or cocaine should be strictly avoided. Relief may be obtained for short intervals by large doses of Valerian, and by small doses of Antipyrine. One Asafetida Pill, given at bed-time every night, can do no harm. The constant current or static electricity may be tried with benefit in some cases.

Where the hypochondriasis shows itself chiefly as an abnormal exaggeration of the symptoms or sensations of some trivial local disease, judicious and successful local treatment should be persevered with in addition to moral treatment.

HYPOSPADIAS.

The treatment of this malformation requires varied, and sometimes extensive, plastic operations, the description of which is outside the scope of the present volume. The reader is referred to the article by Professor Wood in Heath's "Dictionary of Surgery." Minor degrees of the deformity may be left uncorrected since they may cause little inconvenience. The writer exhibited, some years ago, a specimen of artificial hypospadias, which he found in an aboriginal of the interior of Australia. He ascertained from an explorer that at least one tribe in the centre of that Continent performs the serious operation of slitting the male urethra open from the glans backwards, through the perineum towards the bladder, evidently with the view of preventing procreation. A careful examination of the specimen proves to what extent the most serious plastic operations may be carried out when recovery follows a barbarous mutilation undertaken without anatomical knowledge, and performed with the crudest of instruments, and without the slightest conception of the necessity of antiseptic precautions.

HYSTERIA.

Upon the first indications of the presence of hysterical tendencies, the general health of the patient should be carefully looked into. Her diet should be liberal, and administered with frequency and regularity. Active open-air exercise should be insisted upon even to the extent of producing some fatigue. Regular hours for rest are essential. Everything which over-stimulates the cerebral centres is to be avoided, as is also every excitement of the emotions or passions. Healthy and constant mental occupation should be advised, with avoidance of the evils attendant upon social dissipations, with their late hours and unnatural excitements. Sound, wholesome literature, instead of the maudlin, sentimental trash of cheap novels, should be supplied as food for the mind, care being taken that the patient be not permitted to tax the memory or perceptive faculties too severely. Recreations or exercises, as sketching, painting or music, are certainly to be preferred to mechanical needlework or lace-making which permits of too much introspection and moping. Sea bathing and the morning cold bath, when admissible, are valuable adjuncts, and the patient should be strongly advised to retire early to bed, and to persist in early rising.

Any departure from the healthy standard in digestion or assimilation requires to be remedied. Anæmia calls for iron, and

menstrual disorders and constipation demand appropriate treatment.

Where the symptoms have become established, preventive treatment is, of course, out of the question, but the above general measures may be applied with benefit in any stage of the affection.

Moral treatment is of first importance in every case, and if the mental constitution of her immediate friends and relatives does not permit of their treating her with *firmness*, her removal to less sympathetic and more reliable companions, or strangers, is advisable. In very confirmed cases, as will be presently mentioned, rigid isolation must be insisted upon. The physician should take her relatives into his confidence, and make it clear, beyond the possibility of being misunderstood, how her case stands. This is generally only half attempted, and her friends too often interpret the physician's remarks as meaning that the patient is either malingering or labouring under some delusions or fancies. Consequently their management of her, with this erroneous impression, is fraught with disaster. The co-operation of a strong-minded, judicious relative, possessing tact and firmness, though not devoid of sympathy, but capable of suppressing sympathetic manifestations, is of infinitely more value than all the drugs at our command.

The influence of such a mind operating upon the victim of hysteria can be guided by the physician in such a way as to strengthen the patient's will-power and enable her to successfully combat the tendency to yield to displays of emotional disturbances. Lecturing or scolding the patient continually is to be condemned, and ridicule is most injurious. Each case must be managed as the judgment or tact of the physician directs. Sometimes the influence of the strong will of the physician may accomplish results which appear as miraculous. The writer had the satisfaction of being able upon one occasion to cause a patient who was bed-ridden for several years to get up and walk across her room to the amazement of her relatives, who had regarded her as hopelessly paralysed. There cannot be a doubt that very many of the so-called examples of faith-healing are instances of this therapeutic power.

Whilst upon the moral treatment of hysteria, the reader may glance at the remarks made under the head of Hypochondriasis, on page 435.

As regards the use of drugs in benefiting the general hysterical condition, it must always be remembered that they should be considered as of secondary importance when compared with the moral treatment. Valerian has long enjoyed the reputation of being the most valuable member of this class of remedies. To be of any use, however, it must be given in doses much above the strength of those usually employed. Drachm doses of the simple tincture, or an equal quantity of the ammoniated preparation, freely diluted, may be given three or four times a day.

Aposti has reported upon the rapid improvement in the symptoms of hysteria after administering Methylene Blue in pills. As soon as the urine becomes blue the patient commences to improve, and he thinks the drug acts mainly by suggestion.

The Valerianate of Zinc or of Iron is undoubtedly the best remedy which we possess for constant administration in those cases of general neurasthenia and hysteria, whether occurring in the emaciated or plethoric subject. The writer has given the Zinc Salt in doses of 6 grains three times a day as long as the patient's stomach has tolerated it. After nausea or loss of appetite appeared to result from these large doses he generally found the accompanying pill to be the most satisfactory routine treatment:—

R. *Zinci Valerian.*
 Quinnæ Valerian.
 Ferri Valerian. ana gr. i.
 Extracti Aloes Aq. gr. ss. misce.

Fiat pilula. Mitte tales xxiv. In phiala serventur. Sumat unum ter in die post cibos.

Asaetida is sometimes very useful. 5 grs. in pill, morning and night, may be given, and should there be much constipation, 10 grs. of the B P pill may be given at bed-time.

Musk is useless, and Sumbul is generally disappointing.

Bromides are of little service unless in those cases where there are evidences of sexual excitement and insomnia. Their routine administration, especially in lean or so-called neurasthenic subjects, is productive of much mischief. They are certainly more suitable and more clearly indicated in the class of hysterical patients from which the Continental physician forms his experience.

Strychnine is recommended by some authorities. The writer has tried it extensively in varying doses, and never saw it administered without causing aggravation of the symptoms.

Aetæa or Cimicifuga, Arsenic, Pellitory Oil of Amber, Ignatia, Camphor, Galbanum, Bromide of Camphor, Garlic, Cocaine, Antipyrine, and many other substances have been used in a routine way in hysteria. Those of them which the writer has tried have been useless or harmful. It is to be regretted that the multiplicity of so-called remedies tends to divert the physician's mind from the moral and rational treatment of the disease, from which alone the best results are to be obtained. Once the physician has satisfied himself of the absence of organic disease, he must be firm and constant in insisting upon his directions being carried out to the letter, and the constant changing of

medicines and instructions only tends to shake the confidence of the patient.

Alcohol should be avoided, and narcotics are to be prescribed with caution, and such restrictions should be imposed as will ensure the patient against the dangers of becoming enslaved to their use. The Cocaine habit must also be guarded against.

Before proceeding to detail the special treatment indicated for the various local manifestations of hysteria, a brief description of what is known as the Weir Mitchell method may be given. By this treatment cases have been brought under easy and rapid control which hitherto have been considered altogether outside the sphere of practical treatment. It is only in such grave cases that the method in its entirety should be recommended.

The feature of greatest importance in this method is *isolation*. This must be thorough and complete, only the nurse, physician, and masseuse being seen by the patient during the treatment. As a rule, it may be said that the other elements in the treatment are worthless without this strict isolation. Owing to the objections of the patient and her friends much opposition is encountered in carrying out this method in its entirety, but it may be advised that unless they agree to this rigid isolation it is useless to proceed with the plan.

The patient must be removed from her own home to an institution in which suitable provision is made for the reception of such cases, or she may be brought to comfortable lodgings.

The second element in Weir Mitchell's method is *absolute rest* in bed the patient not being permitted even to stand upon her feet for a moment, just as if she were suffering from severe typhoid fever. She is not permitted to use her arms or hands, being fed by the nurse as a child. Letters, books, sewing, and usual ordinary harmless occupations are forbidden for the first few weeks, after which she may be read to for a short time, and gradually these measures are relaxed; but for the first six weeks the horizontal position should be maintained in severe cases.

Overfeeding is the third feature in the treatment. Milk alone should be given for the first ten days, at frequent intervals, and gradually increased as massage is commenced, until enormous quantities are consumed. After three or four days sometimes 8 or 10 pints are swallowed daily. Strong beef tea, chicken soup, meat jellies, tea, coffee, chops, fish, steaks, poultry, eggs, bread and butter, oysters, oatmeal porridge, vegetables of all kinds, puddings, and any form of plain, wholesome, digestible food are administered in very large quantities.

Massage is an important part of the treatment. It should be commenced upon the third day and be carried out in the most thorough manner, gradually extending the dose till an hour's good deep kneading of the muscles and tissues of the body can be borne by the patient. In bad cases, two applications or doses lasting for three-quarters of an hour each, morning and evening, may be

required. At the beginning it is well to confine the operations to the extremities, and the movements should be limited to the superficial structures. Afterwards the deeper tissues and muscles may be kneaded till in a few days the entire body, excepting the head and face receives a fair share of manipulation. In this way the blood and lymph circulations are greatly stimulated, effete products are washed away, waste materials being removed, and fresh pabulum brought with great rapidity to the refreshed tissues.

The enormously increased amount of nourishment is thus used up to the greatest advantage, and the patient's body weight increases to an astonishing extent. Wasted muscles and emaciated limbs become plump and agile, and the change in the patient's aspect and dimensions is such in 10 or 12 weeks' treatment as to tax the credulity of those who had not previously witnessed examples of the method.

Electricity is the last element in the Weir Mitchell plan of treating hysteria and neurasthenia. The uses of electricity will be more fully mentioned under the head of the treatment of the local manifestations in the following few pages. When used as a portion of this method it is employed as an adjunct to massage. The interrupted strong current is selected, and the various muscles or groups of muscles are thrown into contractions.

This treatment has been productive of the greatest good in cases apparently hopeless, but, like every other powerful agent, its use has been abused, and in some cases the disease has been aggravated by its employment. As a rule, those so-called cases of neurasthenia (hysteria associated with great emaciation) are successfully treated by it. Stout subjects suffering from hysteria as a rule do not improve and often get worse under its use.

Brown-Séquard's treatment consisted in the injection of 15 minims of Testicular Fluid mixed with an equal amount of sterilised water, the dose being daily increased till 1 dr. is given for 20 days, then after a rest of 10 days the injections are renewed for 20 days more. The drug may be given by the bowel when hypodermic medication is undesirable.

Luton and others affirm that all the benefits derived from the above and other organic liquids may be obtained by injecting Saline Solutions or artificial serum, consisting of 10 parts of Sulphate and 5 of Phosphate of Sodium in 100 of water. Luton maintains that one injection of 75 minims of this solution once a month will give a weakened and invalid man sufficient energy to earn his living. Crocq corroborates this extraordinary statement.

Babes injects normal brain tissue which he makes into an emulsion with 5 parts of broth; of this about 1½ drs. are injected every day into the abdominal walls. Dana uses similar sterilised products in chronic nerve and brain affections. Paul affirms that he got excellent results in 53 cases, embracing nearly every form

of neurasthenia, by injecting the gray substance of the brain of sheep, diluted with sterilised water.

Hammond injects Cerebrin and Cardin prepared from the brain and heart of the ox. The most recent treatment is that carried out by Walter, who makes a pure culture of the colon bacillus obtained from the intestine or stomach of the hog, and administers it in the form of capsule in the convulsive stage.

The results in all these cases may be considered as unproven, and the same judgment must be passed upon the methods of treating the disease by Hypnotic Suggestion.

Bathing, douches, and cold sprays, preceded by tepid douching, are always very valuable when judiciously carried out in such a way as to secure healthy reaction after brisk friction with warmed towels.

For the special symptoms manifested in hysteria, special treatment may be demanded.

Convulsions. If the physician be called to a patient during an attack of convulsions or of hysterical coma, and if he be confident of the accuracy of his diagnosis, he can have the satisfaction of often bringing the fit to an abrupt termination.

The patient, if in bed or upon a sofa, is so placed as to enable the physician to pour a stream of cold water suddenly from a height upon her face, without saturating the bed-clothes or garments of the patient. This free douching is soon followed by a return to complete consciousness, and in subsequent fits the mention of it is often enough to arrest all symptoms. Sometimes a tumblerful of cold water thrown forcibly against the face acts like magic, but the physician should state in the hearing of the patient that the application is to be repeated every 2 or 3 minutes till she gets out of her attack.

Catching the patient by the nose whilst the mouth is kept closed so as to arrest the breathing entirely for a short period, may arrest an attack instantly. Strong Liquor Ammoniac to the nostrils may produce the same effect.

Pressing deeply over the region of one ovary is said to sometimes arrest a fit of convulsions or of coma, but it often fails, and when it does appear to arouse the patient it leaves her in a very excited and excitable condition. A better plan is to make firm pressure upon the supra-orbital nerve as it emerges from its bony notch.

Electricity is of value if at hand; and by placing one electrode over the front of the neck and the other over the pit of the stomach a smart interrupted current may stop the paroxysm in a few seconds. It has no such effect in epilepsy, and may be used therefore, as a means of arriving at a positive diagnosis of the nature of the fit.

Hypodermic injection of Apomorphia, to produce vomiting, has been recommended in hysterical opisthotonos.

Deep pressure upon the arteries and tissues at the base of the

neck, so as to interfere with the cerebral circulation, as is sometimes successfully tried in stopping epileptic fits, may cut short the attack of hysteria or hysterio-epilepsy.

Whilst carrying out these measures, the room should be cleared of all active sympathising spectators, and the physician should give his orders and carry out his operations without the least sign of hesitancy or wavering. This latter he cannot do unless he be very positive about his diagnosis; indeed, little can be done with hysterical patients as long as the physician has any doubt whatever lingering in his mind about the case being one of genuine hysteria. The patient by intuition recognises his want of confidence in himself, as shown by some very trivial circumstance, and the result is that the demon refuses to be exorcised.

Where the coma has lasted for a considerable time and the douche or electricity has failed, the application of a hot caustic iron gives prompt results. The writer has cut short attacks of both convulsions and coma by giving directions in a loud and firm tone of voice for the heating of an iron and the ordering of a portion of the skin to be exposed for cauterisation. He has, however, never seen a case where the actual carrying out of this measure appeared to be justified. Nitrite of Amyl sometimes arrests the paroxysm.

After the arrest of the paroxysm of coma, or convulsions, or delirium, much remains for the physician to do. The patient should be compelled to attend to all those points already detailed in the commencement of this article, and she should have full doses of the Ammoniated Tincture of Valerian, with some Asafetida, administered at short intervals. The Valerianate of Zinc in 3 grain doses, may afterwards be prescribed for several weeks.

The following nauseous and disgusting combination may be tried:—

R *Tinct. Asafetida* ʒj.
 Tinct. Valer. Ammon. ʒij.
 Spiritus Terebinthina ʒij. *misce.*

Fiat mistura. Capiat coch. min. ex cyatho un. aquæ secundis horis, p. p. a.

Local paralysis should be treated by the means recommended as useful for the general hysterical condition. Massage, Passive Motion, and Electricity, locally employed, afford, in conjunction with moral treatment, the best hope of success. The same measures prove useful in dealing with contractions or flexions, which are also successfully removed by the application of a circular blister around the joint. The method of employing these therapeutic agents will vary with the locality and nature of

the affected parts or organs. Where there is much pain and tenderness over joints or bony prominences a sponge as hot as can be borne without risk of vesicating may be occasionally applied.

Aphonia yields readily to electricity, which may be employed in various ways for the treatment of this affection. By the aid of the laryngeal mirror one electrode is placed in contact with the vocal cords, the other being fastened to the outside of the larynx. By a button in the handle of the interior electrode the current is turned on, and the shock often causes the patient to instantly find the use of her voice, perhaps for the first time for many months. The applications should be repeated till the aphonia entirely disappears. Sometimes one sitting of a few minutes suffices, but more commonly several are required to ensure that no return of the aphonia occurs. The Faradic or interrupted current should be used, and contact may be made 5 or 6 times during each sitting. (See also under *Aphonia* on page 57.)

In the absence of the special electrode required for carrying out electrization of the vocal cords, good results may be obtained by passing a smart interrupted current through the larynx by means of moistened sponge electrodes placed externally over each side of the larynx in the neck. Static electricity may be used; it is, indeed, in this case much more certain than galvanic currents, and its effects are more lasting. It may be used in a variety of ways, the simplest being that of passing a series of shocks through the larynx from a Leyden jar. As the aphonia is, however, only one of the many manifestations of the hysterical state, it will be advisable to administer the static electricity in a way that will affect the entire system. The simplest and mildest method of using it is to place the patient on an insulated stool, or in an insulated chair, and by means of a brass rod held in her hand to connect her body with the prime conductor or condenser of a *Carre*, *Holtz*, or a *Wimshurst* machine. This is called the "static bath." When the surface of the patient's body becomes thoroughly permeated by the positive fluid, the physician approaches with a large wooden ball which he holds at about the distance of an inch from the patient's skin, the electricity passes from the patient through the ball and the operator's body to the ground without producing pain. This is known as the "electric soufflé."

To produce the "electric spark," a metal ball electrode or metal point is brought sufficiently near to the patient's body to cause a sudden discharge of positive electricity.

In hysteria excellent results have been obtained by *Dr. McClure*. His routine method of procedure is to insulate the patient, and for the first two sittings to administer the "bath," afterwards by bringing the wooden ball close to the skin, but not close enough to produce a spark, he moves it in all directions over the body. When the paralysed part or an area of anaesthesia is approached,

the ball is laid aside, and sparks (light or heavy) are extracted by means of metal electrodes. In this way sparks may be extracted from the larynx in hysterical aphonia with much advantage.

Owing to the difficulties in working with static machines, static electricity has not received the attention which it deserves.

General Faradization may be employed in hysteria, as static electricity is administered by the static bath.

The patient stands upon a large metal disc or moistened sponge electrode connected with the negative pole of the battery. Whilst the physician places himself in connection with the positive pole through a wire held in one hand, with the other hand he holds in contact with the patient's body a large metal ball enveloped in a moistened sponge. The current thus passes through his body, and also through the patient as it passes from pole to pole. Either the galvanic or Faradic current may be used.

These are the principal ways in which electricity is employed in hysteria, and it is often impossible to tell which method is the best in a given case till it has been tried. Each method is also capable of being varied. Thus in the treatment of neurasthenia cerebri, where insomnia is the chief trouble, static electricity may be administered by holding the large wooden ball in front of the forehead of the patient sitting in the insulated chair, or the metal cap electrode may be used with great advantage. The writer has had excellent results in such cases by passing a weak, continuous, or galvanic current through the brain by using two sponge electrodes outside the skull, connected with 4 or 8 large Léclanché cells. The use of what is known as "static induction" is not yet sufficiently recognised therapeutically to warrant a description. The same may be said about Galvano-Faradization.

For ordinary cases of paralysis occurring in limbs in hysteria the use of the interrupted current *locally*, generally meets all the requirements of the case. Cutaneous hyperæsthesia and anaesthesia may be dealt with in the same way. When these fail, the general methods should be resorted to with the treatment already mentioned.

Contractures may be treated by slow and steady force, with simultaneous application of the induced current. Weir Mitchell recommends a very large dose of Atropine injected into the contracted muscles so as to cause speedy relaxation, after which manipulation and massage should be resorted to.

Great difficulty will be experienced in the treatment of those grave cases of hysteria associated with, passing into, or alternating with maniacal symptoms, especially when these are complicated with a persistent refusal of food, the only chance of recovery may be to send the patient to a proper asylum. It is needless to say that this serious step is only to be undertaken after the failure of every other method.

HYSTERO-EPILEPSY.

This formidable affection can only be hoped to yield to the measures already enumerated when discussing the general treatment of the hysterical condition. The writer has had splendid results from Amyl Nitrite in stopping the attacks in one well-marked case of the disease. Pilocarpine, hypodermically, has been used to cut short the convulsive attacks. In preventing the attacks, Bromides and Arsenic were decidedly useful, but total abstinence from alcohol and butcher's meat gave better results than drugs.

ICHTHYOSIS.

Internally, drugs are practically useless. There are some physicians who have still a remnant of faith in Arsenic, Cod Liver Oil, and Pilocarpine. Pringle has satisfied himself of the great benefit of Thyroid feeding, which he believes is fairly comparable to the results obtained in myxedema. It is to local treatment, however, that the physician must look for marked amelioration of the symptoms of this disorder.

All the dead epithelial products should, as far as possible, be removed before any local remedies are applied. This is best carried out by prolonged immersion in a warm weak Alkaline bath, with the free use of a pure soft soap, and moderate friction by means of a soft hair bath-glove. The Turkish bath may be afterwards employed with advantage, or any form of convenient hot air or vapour bath may be used. When the scales or plates have been removed, a bland, unirritating animal oil or fat should be gently rubbed in till the skin is brought to the natural suppleness. Lard Oil or Neat Oil is the best, but any vegetable oil may also be used, and a pure Olive Oil, such as is used for salads, is free from objectionable odour. Vaseline or Glycerin may be used for the exposed parts of the body, but, upon the whole, the face and hands are best treated by pure Lanoline, which should be gently rubbed in till it disappears. Suet or Cacao Butter answers well in some cases, and Pringle prefers the official *Glycerinum Amyli*.

The bath should be used once each day for long periods, but theunctions should be performed twice a day. When the skin has been brought to its natural feel and appearance, a hot bath once or twice a week and a daily application of the oil will keep the subject of simple ichthyosis in a tolerably comfortable and presentable condition. Mild cases get on with one thorough unction in the week. In a case occurring in a weak, thin boy, the writer had an excellent result from one thorough application of Cod Liver Oil every week.

The inner clothing should be always of flannel, and in some cases great comfort and benefit may be obtained by wearing *chaïnos* or wash leather under-garments.

In severe cases of ichthyosis hystrix, where there is much hardening, the callosities may be gently scraped or rubbed down with a curette, or dissolved by the application of a lotion consisting of one part of the B.P. Liquor Potassæ in two parts of water.

Salicylic Acid, dissolved in Collodion, may be more conveniently used to destroy the growths, and it will not cause injury to the underlying skin. After the removal of the cakes, an ointment containing 10 grs. of Iodide of Potassium in solution, rubbed up with 1 oz. Lanoline, may be used with advantage. Ichthyol and Resorcin (10 per cent.) or Naphthol (5 per cent.), ointments may be tried in the later stages of treatment.

Where eczema complicates the case, the red, weeping fissures must be treated by emollients before resorting to frictions.

ICTERUS—See Jaundice.

IMPETIGO.

This pustular skin affection, allied to if not identical with ecthyma, is now known to be caused by the staphylococcus aureus and the streptococcus of Fehleisen, and is very contagious when coming in contact with skin that has been bruised or injured. It originates sometimes in superficial abscesses or small wounds, and the pus gets inoculated by the finger nails into various parts of the body. This is the cause of the so-called "Football Impetigo."

As there is always some departure from the healthy standard, feeding, exercise, fresh air, and absolute cleanliness must be attended to. It is probable impetigo cannot exist or flourish upon a perfectly healthy person, hence the importance of looking after everything which improves the nutrition of the body.

Bathing of the parts in warm water should be followed by a Boric Acid poultice, after which the ointments mentioned under Ecchyma may be used when all the crusts or scabs are removed. The Diluted Citrine Ointment answers most cases and speedily cures, or the ointment of White Precipitate diluted with three times its own bulk of Zinc Ointment may be used. Any weak antiseptic ointment is efficacious.

When the scalp is affected, warm bread and water poultices will be often required in addition to persistent sponging till the crusts are removed, after which the hair should be cut close, the entire scalp washed with saturated Boric Acid solution, and an ointment consisting of one part of White Precipitate Ointment and three parts of Zinc Ointment should be freely applied. (See under Ecchyma.)

IMPOTENCE.

When this arises from surgical or mechanical causes operative measures may remedy the failing. The cause, when not depending upon mechanical obstacles, should be ascertained before

treatment is attempted. Many of the cases seeking advice from the physician are in those recently married, and much mischief may be done by the administration of powerful drugs under these circumstances. The situation arises from ignorance and nervousness, and produces sometimes a dangerous depression of spirits. The vast majority of cases of this nature right themselves in a few days if left alone, and all that is generally necessary is a little sound advice and no drugging. The stereotyped instruction to rigidly abstain for a time from all attempts at sexual intercourse is a mistake, unless under special circumstances; nature generally sets matters right in a short time. This is especially true in those cases where emission occurs before penetration has taken place, and then a successful coitus may take place when the act is attempted again a short time after failure.

Moral treatment is all that is necessary in most cases where the incapacity is imaginary. Where impotence arises from previous recent excesses, but where the generative organs have not apparently suffered structurally to any obvious extent, total abstinence from all attempts at intercourse must be rigidly advised till evidence is forthcoming that nature means to assert herself. During this period vigorous exercise, with good living and abstinence from alcohol, with the daily use of the cold shower bath or sea-bathing and tonics, are very useful.

Of tonics, Iron, in full doses of the tincture of the perchloride in combination with Strychnine, is the best. Easton's Syrup of the phosphates is a valuable preparation. It should be given in doses of at least one drachm three times a day.

The ordinary members of the aphrodisiac class, as a rule, do harm and should not be prescribed in these cases. The mere production of an erection is a very different thing from power to perform the sexual act successfully, and these artificial aids generally fail, and after each failure the position of the patient is decidedly worse. For this reason he should be urged not to attempt the act till he feel that he has reason to believe that the attempt will be more successful than the last. In most cases the patient's own sensations will be his guide in this point.

If, however, this treatment fails to cure the impotence, other measures remain, and these may at once be resorted to without waiting in those cases of impotency occurring after middle life, or in those who have indulged in sexual excesses or in masturbation to the extent of causing atrophy of the testicles or penis. In such cases there is often weakness of sexual desire, but sometimes it is not diminished, and the physician finds that the mental despondency associated with the impotence is so serious as to call for active treatment.

Next in value to abstinence and the general hygienic measures just mentioned is electricity in the treatment of premature loss of virility. This remedy may be used in various ways. The writer has observed that the best results follow from the use of a

moderately strong continuous current. One large sponge-electrode being placed over the lower end of the spine, the other is applied to the groin, spermatic cord, testicles, penis, and perineum in succession. The sitting should last for 20 minutes, and may be repeated twice a day. The interrupted current may be employed occasionally with advantage for the space of about a week, during which the continuous is suspended.

Massage, or gentle kneading of the scrotum and testicles, followed by free sponging of the parts with cold sea-water twice a day, has a decided influence in improving the tone and nutrition of the generative organs, and should always be tried in conjunction with electricity.

Benefit may sometimes be obtained from the wearing of a good Pulvermacher chain battery round the pelvis or loins.

Where the secretion of the testicles is not impaired, and where there is no abnormal deficiency in sexual appetite, the incapacity being mainly or entirely caused by some error in the apparatus necessary for erection, authorities speak highly of *Cantharides* in small doses—5 minims of the B.P. tincture—or of *Phosphorus*. The writer has never prescribed these remedies for this purpose, and is doubtful of their utility. Of the so-called aphrodisiacs there is only one, in his opinion, which exerts a decidedly beneficial and harmless action in loss of virility arising from early sexual excesses or premature decay—he has tried it with a success which warrants its recommendation in such cases—viz., *Damiana*.

This is a Mexican plant, the *Turnera microphylla*, which appears to act as a mild stimulant to the genito-urinary centres in the cord. (See Author's work on "Materia Medica," 7th Edition, page 526.) It may be given in doses of one drachm of the liquid extract (1 in 1) three or four times a day, or the following combination may be prescribed with advantage.—

R. *Ext. Damiana Liq.* ℥iiss.
 Tinct. Nucis Vomica ℥vi.
 Sanmetto ad ℥iv misce.

Fiat mistura, cujus capiat drachmam ter in die post cibos ex cyatho vinario aquae.

Ergot, Sanguinaria, Turpentine, Serpentina, Cubebs, and other vaunted remedies are worse than useless. Where the impotence occurs in conjunction with some organic or functional disease, it may reasonably be expected to pass off when the affection is removed, and it is needless to say that appropriate treatment should be directed to the mischief of which it is symptomatic. Thus, in diphtheritic paralysis, lead poisoning, renal affections, diabetes, and ataxia, impotence may be the condition which first directs the patient's mind to the attack.

reached, if dryness of the throat and dilatation of the pupils are not observed. Indeed, it is this great difficulty in arranging the dose of the drug which has led to failure. The physician must be careful not to leave the increasing of the medicine in the hands of inexperienced nurses. There is practically no danger in keeping up the action of the drug for two or three weeks after which it may be gradually diminished, as the bladder soon recovers its normal rhythm when the micturating habit has been thoroughly broken for a short time. Tirard administers the Extract of Belladonna in small pills each containing $\frac{1}{2}$ gr.

The hypodermic injection of Atropine is sometimes resorted to. 1 minim of the B.P. Liquor may be injected in a child of 4 years, $1\frac{1}{2}$ minims in a child of 10 years, and 2 minims in the case of a child of 15 years. These doses should not be exceeded in the first instance; they may be best administered three or four hours before bed-time, and half the quantity may be again injected just before bed-time, if no dilatation of the pupil has been produced. Bromide of Potassium has now and then given good results, but is very much inferior to Belladonna. It may, however, be combined with it advantageously. The following mixture may be prescribed for a child 7 years old:—

R. Potassii Bromidi ℥v.
Tinctura Belladonnae ℥iv.
Syrupi Simplicis ℥i.
Aque Floris Aurantii ad ℥iv. misce.

Fiat mistura, cujus capiat cochleare unum minimum vespere et hora somni.

Strychnine when combined with Belladonna has given excellent results. McAlister has used the following:—Liq. Atropine Sulph. ℥iss., Liq. Strychninae Hyd. m. xlv., Syr. Aurantii ad ℥j. mix. 5 drops are administered before bedtime, and the dose increased till 30 drops are taken, by which time the full physiological action of the Belladonna is evident. He advises the child to be awakened at midnight and again at 6 a.m. The final dosage may in the opinion of the writer prove to be dangerous.

Chloral Hydrate has been highly recommended—the writer has found it to increase the mischief, like Cannabis Indica, Opium, Codeine, and other narcotics, it would appear as if the dreaming which follows the administration of narcotics to children is very liable to excite the bladder.

Rhus Aromatica has given excellent results. Unna states that it acts upon the muscular fibre of the bladder. The writer has used it in the case of a young adult with considerable amelioration of the symptoms. The fluid extract (1 in 1) may be given 3 times a day in doses of 5 minims to children under 2 years, and 10

minims to children of 8 years old. *Rhus Toxicodendron* in small doses has been found to check incontinence of urine, but in no way is it superior to the *Rhus Aromatica*, and it may cause irritation of the stomach and bowels.

Antipyrine has been proved effectual by Phillips, who gives 8 to 10 grs. to children 7 years old and increases the dose, continuing the drug for 3 or 4 months without injury.

Lycopodium, *Buchu*, *Cantharides*, *Ergot*, *Turpentine*, *Creosote*, *Lupulin*, *Nitrate of Potash*, and many other drugs have been used with little success. As a rule, it may be said they fail where *Belladonna* fails.

The methods of painting the orifice of the urethra over with Collodion, or of encircling the penis with plaster or an elastic band, hardly warrant further trial.

Electricity has proved very useful in some cases, but its effects are transient. Picard applies one pole to the membranous part of the urethra in boys, and to the entire urethra in girls, and places the other pole on the hypogastrium, and records brilliant successes.

Where *Belladonna* and *Rhus* fail, Sir Henry Thompson's method of freely cauterising the urethra is likely to succeed. Before this is resorted to a sound or bougie may be passed, and this sometimes answers the same purpose, it may be passed daily for a week. When no improvement results a solution of Nitrate of Silver (10 grs. to 1 oz.) should be injected by a catheter passed down to the prostatic portion of the urethra. In girls the solid Nitrate of Silver may be used to the urethra. In young women 3 grs. of the salt, dissolved in 1 drachm of water, may be injected after the bladder is thoroughly emptied, and repeated in 10 days again; and good results have been obtained by Simms' method of dilating the bladder to its fullest extent by means of large injections of warm water. The injections are made by forcing in a stream of water through a catheter by means of the ordinary elastic enema apparatus, the treatment being kept up till 20 oz. of the liquid can be endured. The writer has had no experience of this treatment, and would be very slow to try it.

Gerbman successfully treats the condition by placing the patient in the knee-chest position and applying massage to the vesical neck through the rectum for two or three minutes.

Gersuny has relieved incontinence by twisting the urethra in the female; he dissects the urethra from its surroundings for three-fifths of an inch, seizes its outer freed border with forceps, and puts on a twist of half a circle, fixing it in this position with sutures; immediate continence results. Frisch, in a case which relapsed, dissected the urethra again, and made a further twist of half a circle, and he holds that this is the best of all operations for incontinence. The passage of an ordinary sound at regular intervals has sometimes given good results. After the cessation of the incontinence, Iron, Arsenic, Nux Vomica, and other tonics

may be given with advantage, and very good results may be obtained by full doses of Strychnine after a decided impression has been made by the administration of Belladonna or Atropine pushed to the extent of producing their physiological effects.

The recent method of submucous injections of sterilized White Vaseline with the view of mechanically lessening the size of the urethral orifice is still upon its trial, but already the dangers of embolism have been demonstrated.

INFLUENZA.

Different epidemics vary so widely as regards the nature and degree of the symptoms that it is difficult to formulate rules applicable to future visitations of the malady. Thus, in the last great epidemic (1890), which passed over the greater part of the world, catarrhal symptoms were often absent, in former outbreaks catarrhal symptoms have been prominent, and this will, perhaps, in the future, be also true. There are, however, fixed features in every epidemic which indicate clear lines for rational treatment. Foremost amongst these is *prostration*. The great epidemic has afforded ample opportunities of studying this symptom, which was invariably the most prominent and the only feature constantly present.

The disorder is caused by a microbe, and the striking prostration is the result of the action upon the nerve centres and muscles of the poison which it manufactures during the brief period of its growth and development. The symptoms are not unlike what occur in diphtheritic paralysis, and the indication is the same—to promote elimination and to keep up the strength of the patient from the very first with the most sustaining diet, as concentrated beef essences and nutritious soups, &c. The intense headache and pains in the back and limbs, even when very little fever is present, should be relieved by Antipyrine (10 grs.) administered at the beginning of the attack, and half this quantity given every four hours generally affords very speedy relief. The action of the drug upon the skin hastens the elimination of the poison and cuts short the course of the affection. The writer prescribes 5 grs. Antipyrine, and half this amount of Citrate of Caffeine immediately and half the dose every hour for six or eight doses, this invariably gives speedy relief. Many physicians prefer Salicylate of Soda alone, or in combination with decoction of Cinnamon. The patient should be put to bed at once, and warm clothing and a little hot stimulant assist the action of the drug.

Complications are apt to be of a very asthenic type, and demand stimulating treatment, with brisk counter-irritation. Depressing expectorants, like Antimony and Squill, should be avoided, and pulmonary congestion, which often exists without passing into pneumonic consolidation, can be best met by full doses of Quinine, in conjunction with tea-spoonful doses of the

Aromatic Spirit of Ammonia, given mixed with a little whiskey or brandy and well diluted with water. The following is a safe and efficient stimulant in such cases :—

R. *Ammonia Carbonatis* ℥iv.
 Tinctura Cinchonæ ℥iss.
 Spiritus Ammonia Aromat ℥iv.
 Decocti Cinchonæ ad ℥xii *misc.*

Fiat mistura, curus capiat ℥i. cum ℥ss. succi limonis dum effervescencia quartis horis p p. a.

Yeo insists upon Quinine as the best of all drugs in influenza; he believes it to be really an antitoxin, and he recommends from 1 to 3 grs. dissolved with 20 grs. citric acid to be taken every 3 or 4 hours in an alkaline mixture of Carbonate of Ammonia and Bicarbonate of Potassium. This treatment, he states, prevents complications and sequelæ.

Vomiting should be relieved by emetics to the stomach region and small quantities of iced champagne. Hydrocyanic Acid should not be given for this purpose, owing to the cardiac weakness generally present.

Rheumatic symptoms, such as severe joint pains, if not relieved by the early doses of Antipyrine, may be treated by 15 grains of the Salicylate of Soda every four or six hours.

Diarrhœa should not be interfered with unless it becomes excessive, when the Dilute Sulphuric Acid (30 minims) may be given in combination with Tincture of Opium (10 minims) after each loose motion. Should the motions still continue frequent and excessive 20 grs. Tannalbin with 10 grs. Salol may be ordered in combination with 1 grain of Opium.

Food and stimulants in severe cases should be administered with regularity and persistence, and even rectal feeding may be required in very bad cases. It is of the utmost importance that the patient be seriously cautioned to remain in bed or in his room till convalescence is established. Many lives were sacrificed in the great epidemic by patients exposing themselves outdoors before the prostration had passed away, pneumonia being commonly the result. The attack is perhaps more influenced by an immediate resort to bed upon the first symptom appearing than by drugging. Isolation, when practicable, should always be carried out. The writer satisfied himself thoroughly during the great epidemic that the pneumonia which followed the attack of influenza was distinctly infectious, and this complication or sequela should be treated by strict isolation.

Pneumonia requires a free administration of stimulants, and the danger of cardiac asthenia must be met by large doses of Strychnine combined with Digitalis and Oxygen inhalations. For the

persistent cough which often remains long after the febrile attack has passed away the writer found that 3-gram doses of Iodide of Potassium combined with Ipecac. and a little Morphia gave the best results.

INGROWING TOE-NAIL.

In mild or trivial cases the trimming or clipping of the free margin of the nail, scraping of the dorsal surface with the edge of a bit of glass or with the knife, so as to reduce its thickness and to produce a tendency to curling upwards or backwards of its lateral margins, and the removal of any cuticle accumulated under the ingrowing edges of the nail, are all that are required to give relief and prevent further progress of the mischief.

Pressure must be avoided in all cases, and the boot should be made sufficiently roomy, to prevent it pressing against the tender part by having the inner margin of the sole so made as to end in a good square toe; the modern fashionable tapering-toed boots are the cause of ingrowing toe-nails in many instances.

Where ulceration has occurred, a minute roll of lint shreds should be neatly packed down between the tender overhanging skin and ingrowing edge, so as to insinuate itself under this edge and cause elevation of it. Strapping should be then applied, so as to retain the lint in its position and at the same time to drag upon the overhanging integument and keep it pulled away from contact with the ingrowing edge. The lint may be removed at the end of a few days and the space filled with Boracic Acid powder, Iodoform, Nitrate of Lead, Alum, Oxide of Zinc, or with the following powder:—

R Pulv. Iodoformi ℥iv.
Calamina Preparat. ℥ii misc.

Exuberant granulations may be destroyed with Nitrate of Silver, Sulphate of Copper, strong Solution of Perchloride of Iron, pure Carbohc Acid, or Acid Nitrate of Mercury. Sometimes repeated applications of these caustics may at the same time destroy the sharp ingrowing edge of the nail.

Where caustics fail, cocaine having been injected into the skin and subcutaneous tissues, or the part being frozen with the ether spray, the overhanging granulations and integument may be shaved clean off by means of a sharp scalpel and the wound left to heal under antiseptic dressings. This method, if skillfully performed, often gives better and more lasting results than those following the operation of evulsion of the nail.

There is great temptation to simply pare or shave off a strip of the nail parallel to and including the ingrowing edge, but as a rule this does not lead to any permanent benefit.

There are decided improvements upon the old-fashioned

method of inserting a roll of lint between the granulations and the under surface of the ingrowing nail. The best of these is carried out by using thin sheet Lead instead of Lint. A thin layer of beaten-out Silver also answers very well, but Tinfoil is still better. It should be inserted under the edge of the nail, so as to thoroughly elevate it. This can rarely be accomplished at the first application, but in a few days the amount packed under the edge may be increased till the required elevation is accomplished. At the same time the foil may be gently packed in between the sharp edge and the over-hanging granulations, the part dusted over with Iodoform and enveloped in strips of plaster. It need not be changed for several days. This method, if carefully adopted and persisted in, generally removes the trouble. Where, however, it fails and the nail is loosened by the ulceration involving a considerable portion of the surface of the matrix, there remains the operation of removal of the nail. This is easily accomplished, when the patient is fully under the influence of an anæsthetic, or under local anæsthesia, by inserting one blade of a pair of dressing forceps under the centre of the nail to its root and securing a firm grip as the blades are closed, and by firm traction the nail is removed.

Sometimes one half of the nail may be removed, after previously cutting it in two, by inserting one blade of a pair of fine and sharp-pointed scissors under its centre and pushing it down to the root. The loosened portion may then be easily removed by the forceps. Powdered Boracic Acid being freely applied, the wound may be enveloped in lint moistened with Spirit Lotion and surrounded with oiled silk.

Cottin's method of treatment is radical and successful. It consists in removal with the knife of the diseased fleshy parts, together with a large and thick slice of the healthy and adjoining side of the toe. The cut should extend far back and be guided by the edge of the nail, which should be exposed but not injured by the incision.

Hofmann has treated ingrowing toe-nail by pouring a few drops of a strong solution of Ferric Chloride upon the ulcerated spot, after elevation of the nail by means of bits of cork. The part is then permitted to dry, and the application repeated on the next and following day after. In a few days, upon removal of the resulting hard crust, the nail is found to be soft and friable, and easily removable with scissors. The writer has no experience of this method, which does not promise to supersede the older plans of treatment.

The following plan has been reported as most satisfactory by Purckhauer, it is bloodless and painless, and does not cause the patient to lie up. The nail is moistened with a warm 40 per cent. solution of Caustic Potash, and in a few seconds, as the surface becomes soft, it is scraped with a piece of glass, after which the solution is again applied, and scraping repeated till the portion of

nail to be removed is as thin as paper, when it can be lifted up with forceps and cut with scissors easily.

INSANITY.

To deal even in the briefest way with the treatment of the various forms of insanity is beyond the scope of the present work. Dementia, mania, melancholia, idiocy, moral mania, monomania, and their varieties, would require for a description of the necessary details of treatment space far beyond that at the disposal of the writer of the present volume. Moreover, these details can only be carried out in institutions specially designed for the purpose, and furnished with elaborate machinery for isolating, watching, nursing, dieting, exercising, amusing, and instructing the victims of mental disorders. To undertake the care and management of insanity in the patient's home would be in the vast majority of cases a serious mistake and a cruel wrong to the patient, whose chances of recovery would be seriously diminished by such a proceeding.

The earliest possible removal to a suitable institution is of the utmost importance and, as a rule, it may be said that in acute cases every day's delay diminishes to some extent the chance of permanent restoration. Where the patient's ailment is such as does not prevent his travelling and mixing with the public, his early removal from home under the watchful care and close surveillance of a physician during a prolonged tour by rail or sea may be fairly tried with some hope of success before resorting to the restraints of an asylum. Such cases are, however upon the whole, rare where this method of treatment is available or warrantable soon after the outbreak of an attack.

The treatment of the various forms of insanity by drugs resolves itself into the judicious administration of remedies, with the view to correct the many deviations from the normal physiological state which may exist either as the cause or as the result of the abnormal state of the mind. Thus tonics for loss of appetite, and Cod Liver Oil, Iron, and other restoratives are indicated when emaciation or anæmia exists. Feeding is an all important element in most cases, and often it must be carried out by the stomach pump or nasal tube and syphon. Adam advocates the open air treatment as in the Nordrach system, with very generous feeding. Beyer recommends the use of a bath at 95° F. for hours at a time, the patient spending his day in the bath, where he takes his meals, and is moved from the bath to bed at night. Narcotics should be avoided, except when pure hypnotics fail.

Sleep should, speaking generally, be insured. The favourite drug is Chloral; but the writer, knowing its dangers when administered to sane patients, and having very little experience of it in insanity, hesitates to say anything in favour of it. Hyoscine has given excellent results in several large asylums, and the hypodermic injection of $\frac{1}{16}$ grain of pure Hyoscine Hydro-

bromide generally produces the most desirable calm and sleep. Dubossine which is almost identical in therapeutic action, is also much praised. Sulphonal, Trional Paraldehyde, Chloralamide, and other hypnotics may be used according to their recognised indications. Opium and its alkaloids are generally objectionable. (See following article.)

INSOMNIA.

All attempts at classifying insomnia are unsatisfactory, its causes are so numerous and varying. An elaborate description dealing with the treatment of all these would fill a volume many times larger than the present handbook. Hence reference will only be made to the treatment of sleeplessness depending upon the causes most commonly met with. It is hardly necessary to say that in every case the first thing is to ascertain, if possible, the cause of the insomnia, and in many instances its removal will be followed by the disappearance of the sleeplessness. Thus the writer has often seen insomnia to depend upon a cup of strong tea taken late in the evening, and the patient not suspecting the cause continued to drink tea till the insomnia became alarming.

Any sudden change in the hours of diet may be followed by insomnia, thus some patients cannot sleep after a late supper, whilst others fail to get any sleep if they retire to rest with their stomachs empty. Sleep may only come to those who retire to bed immediately after wearing the brain with active exercise. Others may be wholly unable to sleep if any previous mental activity has been indulged in. It is a very common experience to find amongst active brain workers that sleeplessness follows after taking a day of rest and calm, and often the freedom from care and repose of the Sabbath results in the loss of sleep for the night. This is, of course, an unnatural condition, and deserves serious consideration.

Mental anxiety, grief, exciting passions, dyspepsia, hepatic congestion, cardiac affections, many acute diseases, mania, insanity, delirium tremens, cerebral tumours, cold feet, and all conditions associated with pain, call not for treatment of the insomnia so much as for the relief of the above-named conditions which produce the insomnia.

A very common error is to confine the management of the case to the administration of narcotics and hypnotics. These should never be employed except when simpler measures fail. Especially in chronic cases, the last thing which the physician resorts to should be a narcotic or so-called hypnotic.

Regarding sleeplessness as the result of the transgression of some law of health, the patient's mode of life should be minutely examined with the view of finding out the transgression and remedying it. Unfortunately, the insomnia may remain for a considerable time after the cause has been removed. Wholesome diet, change of scene, a sea voyage, free open-air exercise near

the sea if possible and persisted in till fatigue is felt, the avoidance of all mental overwork, and, as far as possible, of anxiety and worry, should be advised.

The writer has found that a long, smart walk just before bedtime is an excellent hypnotic, if the patient upon finishing it retires immediately to his room, undresses without sitting down, and goes to bed. Cold feet must be warmed and rubbed till tingling is produced. Robust patients can dip their feet for a few seconds into cold water, and restore the local circulation by having them rubbed briskly with a coarse towel. Feeble folk must generally fall back upon the objectionable hot-water jar or India-rubber bottle. Cold water bandages to the forehead or scalp seldom do much good, and may keep the patient awake by causing discomfort locally. A hard bed is often better than feathers, and a hop pillow may have a good moral effect. Where the patient tolerates it, elevation of the head is a decided advantage, especially where there is want of vascular tone. There are some who fancy that they can sleep better when their bed is placed due north and south. All sorts of devices are recommended for wearying the brain, such as counting up numbers, repeating verses, &c.

The influences of monotonous noises or vibrations to which the patient has been long familiar, as the hum of city traffic, the sound of machinery, of running water, &c., are often productive of good. The writer knew of an instance of protracted insomnia in the wife of a blacksmith, which, after failure of all hypnotics and absolute stillness, yielded to the music caused by the loud hammering on an anvil in the forge beneath her bedroom. He has witnessed an hospital patient who could not sleep till she got a small and rather noisy clock from her home and placed it by her bed-side. Thus perfect quietude is not *always* desirable.

A copious warm drink or a cold water draught before lying down occasionally soothes some patients. The habit of reading oneself to sleep by the aid of some uninteresting author, though not to be recommended, is often efficacious. The absence of light is generally essential, and the morning sun should be shut out by blinds or shutters.

Massage is a powerful hypnotic, and the writer has seen very wakeful and neurasthenic patients fall asleep during the performance of it. Sometimes, however, massage may excite. Eccles's plan is the best. He advises thorough rapid massage of the abdomen, thighs, and legs, so that a temporary anemia of the brain may be produced by the blood flowing into the dilated vessels of the manipulated regions. A warm or hot compress to the abdomen tends to prolong the dilatation of the abdominal blood vessels, and sound, refreshing sleep often supervenes.

Hydrotherapy is a valuable aid in treating insomnia, and in some cases gives permanent relief. A warm bath should be taken till the patient is almost beginning to feel weak. He may then be

enveloped in a flannel bath-sheet, and when lying on his bed upon the top of the bed clothes his body should be perseveringly rubbed down by an attendant with a linen Turkish towel till a grateful sense of drowsy languor is felt, after which he should get under the bed clothes. The Wet Pack may be employed for 35 minutes with advantage, but it will be better to use a sheet wrung out of tepid or warm instead of cold water, as generally recommended. Friction with a rough warm towel should be afterwards employed, and the amount of over-clothing should not be such as to encourage profuse perspiration which may keep the patient awake. The local pack to the trunk may likewise be employed with advantage, and after getting to bed its good effects may be kept up by giving warm or hot drinks.

The Cold Douche has been recommended, and is valuable in allaying the cardiac excitement upon which the insomnia may depend.

Gellhorn uses a piece of calico, 18 inches wide and nearly 3 yards long, rolled up like a bandage, and a third of it wrung out of cold water. With this he bandages the leg, the wet portion being carefully covered up by several layers of the dry part as well as by a layer of gutta-percha tissue, and a stocking drawn over the whole; the dilatation of the vessels which follows diminishes the amount of cerebral blood and induces sleep, especially where there is any cerebral congestion.

Electricity has in many cases given excellent results; it may be used in many ways. The writer employs a weak constant current of 5 cells of a Léclanche battery, with one electrode on the forehead and the other on the occiput for 5, 10, or 15 minutes. The interrupted current to the spine, alone or in conjunction with massage, has been used in some cases with satisfaction.

The best results, however, are obtained from static electricity. After insulation of the patient upon a glass stool, his body is brought into connection with the conductor of a Carré or Holtz machine, and when thoroughly electrified a fine metal point is held opposite several spots on the scalp and forehead not near enough to produce a spark. The sensation is as if a light wind or breeze was pleasantly playing over the region, and McClure has found sleep come on whilst this form of electric souflee was being employed. The production of heavy sparks is not necessary or advisable, but the use of the metal cup and static insulation gives the best results which can be obtained from electricity.

Recently Sloan has reported excellent results in 46 cases treated by Faradisation of the head. His method of using the current and the instruments used by him are described in the *British Medical Journal* of June 29th, 1901.

Where the above-mentioned remedies fail, the physician then feels himself driven to employ drugs of the narcotic or pure hypnotic class. The fear of creating a habit which may enslave the patient for life should always be kept before the mind of the

physician, especially in cases where the condition has lasted for a long time. In dealing with insomnia of short duration, this is not at all a probable danger.

Of the drugs used to counteract sleeplessness, there is not, on the whole, one so generally valuable as Alcohol in most mild cases. As remarked elsewhere by the writer, the various spirituous beverages have very different therapeutic actions, which cannot be explained by their alcoholic strengths. Thus for insomnia the various wines are inferior to whiskey, and brandy does not produce as good results as whiskey. Strong ale is highly hypnotic, and so is porter or stout. To obtain the best hypnotic effect from Alcohol, it should be given in one full dose just as the patient has undressed and lain down in bed. It acts more certainly if given warm, but not hot. One wine-glassful (2½ fluid ounces) of good whiskey, made into warm punch, and swallowed as a draught—not sipped in spoonfuls—is a most invaluable soporific. Where the physician has reason to dread the formation of the alcohol habit, it may be mixed with a bitter, or may be forbidden altogether after a short time. The danger of intemperance is much greater when Alcohol is ordered to be taken with meals, but this danger, when the drug is used in simple insomnia, should never be lost sight of.

It is, moreover, surprising to notice, when the patient abstains from the use of Alcohol at all other times, how the same dose may continue to produce its beneficial hypnotic effects without requiring augmentation for long periods. Headache and malaise seldom follow, and when they do, they may be prevented by using a purer whiskey of greater age.

The product of the patent or silent still should be condemned. The amylic alcohol which it contains, though very small in amount does not mellow or split up into the various ethers which develop during the progress of time in the liquid produced by the old pot still.

With few exceptions, the drugs employed to produce sleep up till recent years were selected from the group of narcotics, nearly every member of the group being more or less used for this purpose. The introduction of the pure hypnotics, whose properties will be mentioned later on, has marked an era in therapeutics. Nevertheless, narcotics must ever hold a high place, being invaluable in many forms of insomnia, where the pure hypnotics are useless.

Opium is the most prized member of the group, and its superiority over the new hypnotics lies in its power of relieving pain and distress. As a rule, it may be said that the new hypnotics have no influence over pain, and until it is relieved their action fails to induce sleep.

Opium possesses the power of relieving pain by preventing the conduction or perception of painful impressions, and sometimes this can be done by employing doses so small as to have no

soporific effect whatever. As sleeplessness is so very often caused by pain in the innumerable instances of diseased action coming constantly under the notice of the physician, it must be used often to induce sleep as in neuralgia, sciatica, pleurisy, cancer, angina, &c. In simple chronic insomnia, whether produced by mental over-work or occurring in the insane, and when not caused by or complicated with pain, Opium or its alkaloids should not, as a rule, be employed.

As the present article deals chiefly with such simple insomnia, little space need be given to the discussion of narcotics. The danger of inducing the opium or morphia habit is so great in chronic insomnia that the indications for these remedies should be strong indeed to tempt the physician to prescribe them. Where the insomnia is of very short duration, and caused by mental worry or over-work, which is not at all likely to be repeated or become a habit—in short, where the cause is fleeting, or has already fled, Opium is an invaluable hypnotic, and may be employed in such a case with great advantage. The dose should be a full one, $\frac{1}{2}$ or 2 grs. of Opium, or 30 minims of the Solution of Morphine. The dose should be given as the patient lies down, and darkness and quiet should be maintained. If sleep does not result in two, three, or four hours, the same quantity may be again administered.

When Morphia is administered hypodermically as an hypnotic for the first time, a dose of Alcohol should be given a few minutes before it, or a minim of Solution of Atropine should be injected along with it. When pain is present, larger doses of Opium or Morphine are required, and it is, as a rule, better in such cases to repeat the dose at a shorter interval than to give one very large dose. In chronic bronchitis with profuse secretion, in the late stages of phthisis, in congested states of the brain with contracted pupils, in renal affections, and in all the ailments of childhood or infancy, Opium is contra-indicated.

In the insomnia of delirium tremens, Opium or Morphia may be given in large doses. (See page 194.)

In the painful insomnia of cardiac distress, hypodermic injections of Morphia ($\frac{1}{2}$ gr.) often give great relief and sound sleep when every other hypnotic has failed.

In acute melancholia or mania, Morphia is still sometimes employed, but the newer hypnotics are generally far better. Codeine, Narceine, and Bimeconate of Morphia and the various preparations of Opium, as Black Drop, Battley's Sedative, Nепenthe, &c., may be tried where the after ill consequences of Opium have been barriers to its use. Codeine is a very feeble hypnotic. Opium or Morphia may be combined with most of the new hypnotics, and the writer has often relieved pain with small doses of Morphia, and afterwards induced sleep by 20 grs. of Sulphonal. The dose, even when the minor action of Morphia only is required, will generally need augmentation, and this is one of the chief objections to the use of opiates in insomnia, and all chronic

conditions associated with sleeplessness. The Meconates of Nareeine are recommended by Laborde as less likely to produce malaise and headache. Peronin (Benzoyl-Morphine Hydrochloride), has given good results in the insomnia of general paralysis in doses of $\frac{1}{2}$ to 1 grain dissolved in a little whiskey or water. Dionin (Ethyl-Morphine Hydrochloride) is also useful, especially in the insomnia of the morphia habit. It may be given in $\frac{1}{2}$ grain doses.

Cannabis Indica is open to nearly all the objections to which opium is liable, and hence it is not a suitable drug in the treatment of simple chronic insomnia, and moreover it is most uneven, and very often fails entirely to induce sleep. It does not, however, exert such deleterious influence over digestion, nor does headache so frequently accompany its administration even in large doses. Cannabin Tannate is an excellent form for prescribing the drug in doses of 5 to 10 grs. in the insomnia of mania. Cannabinol is also recommended in similar conditions.

Hyoseyanus has been long used as an hypnotic. It is but seldom employed now, unless in combination with bromides.

Hyoscine, which is a syrupy alkaloid obtainable from hyoscyamus, and which forms crystallizable salts, is one of the most valuable of the hypnotics which have been recently introduced. It is now obtainable in such purity that a dose of $\frac{1}{10}$ grain of the hydrobromide (B.P.), administered hypodermically, is a powerful soporific, producing deep, quiet sleep in 20 minutes, which lasts 6 or 8 hours and leaves no ill consequences after awaking. In acute mania and other conditions of grave excitement with motor disturbance it is a most rapid and certain hypnotic.

Krauss states that after its administration the maniac collapses as if struck by lightning, but the calming down of the general paralytic is gradual, his restlessness soon settling down into peaceful slumber. The drug is not without its drawbacks, and though many observers assert that it has no influence upon the heart, nevertheless it is apparent that a remedy of such potency is not one to be employed in a routine way in the treatment of simple chronic insomnia. Some authorities have reported sharp depressant effects from $\frac{1}{2}$ grain, and it will be wise to regard valvular disease as a contra-indication to its use. In insomnia associated with or depending upon a latent strain of insanity, Hyoscine is the most reliable weapon in our armoury. The drug may be given by the mouth.

 Tinctura Auranti ʒj.
 Aqua Destillata ʒiii. misce.

Fiat solutio, Sumat drackmam hora somni.

Hyoscyamine is still occasionally used. It may be given in somewhat larger doses than hyoscyne, to which, as an hypnotic, it is decidedly inferior.

Bromides of Potassium and Sodium are certainly the least harmful of hypnotics. In mild cases of insomnia following prolonged mental activity and over-work, full doses (30 to 45 grs.) of the potassium salt produce calm, deep, refreshing sleep. In severe cases it very often fails, but failure does not leave the patient in a worse condition than if he had not taken the drug. The cases where its best effects are uniformly observed are those where sleeplessness is caused by mental over-activity, a state not of simple wakefulness, but where the brain is unusually active, and the mind excited by a rapid succession of brilliant ideas. This condition often supervenes upon the patient retiring to rest immediately after some mental effort or worry, without permitting a period of rest, during which the mental faculties should have been diverted into other channels. In this state there is some flushing of the face, and throbbing of the carotids and pulsations are felt in the cranium. The brain feels like an active galvanic battery, and new thoughts arise in rapid succession, and the patient feels a capacity for mental work to which he was unequal in the hours of the day. This is a very frequent experience in public speakers and debaters. If 30 grs. of bromide produce no effect in an hour under these circumstances, the dose may be repeated and if sleep does not soon follow, a full dose of warm whiskey punch will rapidly produce sound slumber. There is a state of restlessness of a totally different sort often observable in highly nervous patients after getting into bed, in which the slightest external stimuli call forth incessant and ineffectual attempts to dispose the limbs, head, or trunk in such positions as will give a sensation of comfort and tranquility. This, which might be called "acute fidgets," is controlled effectually by a few doses of the bromides, which probably act by diminishing reflex excitability.

The bromides may be taken for long periods without hurt. In one patient with a bad family history of insanity who suffered from insomnia, the Bromide of Potassium, combined with a small dose of Tincture of Hyoscyamus (20 minims), was steadily taken almost every night for 25 years with most satisfactory results, and with no necessity for augmentation of the dose, and with no ill consequences.

McLeod, in acute mania, induces "bromide sleep" by administering 2 drs. of Sodium Bromide in 5 oz. water every two hours during the day until 1 oz. is taken, and this quantity is repeated during the second day.

Chloral has been extensively employed as an hypnotic in simple insomnia and delirium tremens. It is, perhaps, the most certain soporific which we possess when pain is not present. It is open, however, to two serious objections which probably will ultimately

lead to its disuse as a therapeutic agent. These are the dangers of establishing a chloral habit, and the depressing influence which the drug exerts upon the heart. It directly affects the cardiac muscle, dilates the arterioles, and may injuriously affect respiration. These effects have frequently followed the medicinal doses still believed by many to be safe, and death has resulted. Generally sleep is profound and refreshing, and the after ill consequences are trivial. It acts rapidly, and the slumber may be prolonged to ten or twelve hours. Its depressant action should distinctly forbid its use in cardiac disease, in emphysema, and bronchitis, and in the late stages of typhus and typhoid insomnia, when the cardiac muscle is always weakened.

In mania and in the sleeplessness of the various varieties of insanity, its soporific virtues are so uniformly experienced that there is a great temptation to employ it in a routine fashion. Though many patients have taken it without any ill effects in these diseased conditions for many months, there is always a remote possibility of a lethal action upon the heart. This is especially liable to ensue when the dose has been increased, and the fact of its having been previously taken with great advantage is no safeguard against its depressant cardiac action upon some future occasion.

It is no use to combine it with digitalis with the view of lessening its evil action upon the heart, as often advised. The digitalis has no cardiac tonic action for some hours after being swallowed, whilst the chloral may act injuriously in a few minutes.

It acts rapidly, and should be given immediately before retiring to rest, and as some patients are very susceptible to its influence, it is wise never to begin with a larger dose than 20 grains.

It has been combined with Morphia or bromides with advantage, and the writer believes that one or two ounces of whiskey given at the same time greatly increase its efficacy, and materially diminish its power of depressing the heart. Some authorities strongly condemn the combination of Chloral and Morphia as the most dangerous of hypnotics. The writer cannot confirm this judgment. The value of the bromides when given with Chloral is above dispute, as a smaller dose suffices.

The following combination may be tried :—

Butyl-Chloral Hydrate possesses many of the good qualities of Chloral, and is less dangerous. It is, however, a decidedly weaker hypnotic unless where sleeplessness is caused by some painful condition of the fifth nerve. It is in these latter instances that it is generally employed, and as a pure hypnotic it has not met with a success warranting its administration, except where the more trustworthy agents have failed.

Chloralurethane or Ural is an hypnotic obtained from chloral by precipitating a solution of urethane in chloral by adding hydrochloric acid. It is claimed for it that the urethane counteracts the depressant cardiac action of the chloral. It produces, in 40 gr. doses, deep sleep, but sufficient corroboration of the high praises bestowed upon it by Poppi has not yet been forthcoming. It has been observed to lower the blood-pressure.

Somnal is the name given to Ethylated Chloral Urethane, which in 30 grain doses acts like chloral, and is said to be free from its serious drawbacks.

Chloralamide is another new hypnotic prepared by combining chloral with formamide. It is in the form of small colourless, odourless, slightly bitter crystals, soluble in water. 30-45 grs. is the dose most frequently employed and it may be administered by the rectum without causing irritation.

Sleep comes on in less than one hour. It seems somewhat less powerfully hypnotic than chloral; but there is no dilatation of the arterioles or fall of blood-pressure, and as yet no depressant influence over the heart and respiration has been noticed. Like chloral, it would appear to possess some very feeble pain-relieving properties. It is indicated in the same class of cases as chloral and in simple insomnia. It has already been used as an hypnotic in heart diseases and bronchial affections; its hypnotic power is roughly calculated at $\frac{1}{4}$ of chloral hydrate. It is claimed for this drug that for very long periods the dose need not be increased, and that it tends to establish a *habit* of sleeping after its administration has been suspended. It is also claimed for it that it is one of the safest hypnotics, but it must be acknowledged that it is less certain than chloral. The same may be said of Chloralamide.

Chloralose (a compound of chloral and glucose) has given excellent results. It is given in doses of 4 to 10 grs., and it is claimed for it that it causes less digestive derangement than any other hypnotic, that it is much less dangerous than chloral, but perusal of recent reports shows that it is less certain. It has one great advantage over chloral, inasmuch as it raises the blood-pressure. The maximum dose is 15 grains.

Chloral Antipyrine, or Hypnal, is vaunted, but it is heir to all the objections raised against chloral in the ordinary hypnotic dose (20-25 grs.).

Sulphonal has been one of the most valuable of the many recent additions to therapeutics. It may be given in doses of from 15 to 40 grs. It is the type of a pure hypnotic, and possesses no

analgesic properties. In small doses it possesses the remarkable power of checking or preventing the night sweats of phthisis.

In cases of simple insomnia uncomplicated with pain it is with tolerable certainty, and it is altogether free from objectionable qualities possessed by chloral. Thus experience has proved that no sulphonal habit has been observed and can be taken for long periods, but since it appears to have some cumulative action, its use should be suspended for several days before beginning a new course, otherwise hæmorrhagic porphyria may take place. Sleep does not come immediately, sulphonal being very slow in its action and sometimes three or four hours elapse before the soporific effect begins to manifest itself. The duration of its action is about chloral six to eight hours. It has a prolonged deferred action which sometimes causes a drowsiness, which may last for a considerable part of the day following its administration. This is more liable to happen when it has failed to induce sound refreshing sleep after the usual interval. It has been very often noticed that this drowsiness extends into the following night and some patients who use the drug constantly, find that it produces its effects upon the second night without taking any more of the drug in the meantime. Hence the writer has adopted the practice of only giving sulphonal in full doses every alternate night in simple insomnia. There is no depressant cardiac action, and the respiration and arterioles are not influenced. Restlessness, hallucinations, vertigo, giddiness, and confusion of thought, has sometimes, though rarely, been noticed to take the place of sleep.

Ataxia with staggering gait, has been several times noticed and after full doses the inco-ordination has appeared to resemble drunkenness. In one highly nervous patient afflicted with severe insomnia the writer was informed that most miserable depression followed its administration, but this was in a subject in whom almost every known hypnotic had produced unpleasant or alarming symptoms. Several cases have been recorded of serious prostration and coma, and a few deaths have been directly attributed to the drug.

Thirty grains partially dissolved in a little warm beef tea or hot water should be given about an hour before retiring to rest. If a moderate dose of whiskey punch be substituted for the hot water the most unobjectionable and certain hypnotic combination will be obtained. When the alcohol is combined with it, the dose should be given as the patient retires to bed.

The writer has noticed that when dissolved in hot punch its effects are very rapid. It has been pointed out that if dissolved in boiling water it will not fall down as cooling occurs, but the quantity of water must be large in order to effect the solution of a full dose. The writer generally gives it in fine powder, made up as a sandwich between two pieces of thin bread and butter, and

owing to the insolubility of it in this form, it should be given two or three hours before bed-time. If dissolved in boiling water it may be given upon lying down.

From the above remarks it will be noticed that the range of sulphonal is most extensive. It may be given in the sleeplessness of every disease where pain is absent, and it is upon the whole the best remedy for simple insomnia. In insanity however, it is inferior to paraldehyde and hyoscine, in the opinion of those best calculated to judge and in all depressed states of the mind its action is less certain. It is the best soporific for children.

Trional is sulphonal with a methyl displaced by an ethyl group. It has taken the place of sulphonal in the practice of many physicians as a pure and unobjectionable hypnotic, being less cumulative and more rapid in its action and not so likely to cause prolonged drowsiness and headache or other nervous symptoms, but it is therefore without any sleep-giving power upon the second night after its administration. It may be given like sulphonal in doses of 20 to 30 grs. just before retiring to rest, and it is very suitable for children. It sometimes accumulates, and it is a good rule to watch the urine for hæmatoporphyrin. Tetronal acts like trional, but it is cumulative and less reliable than either sulphonal or trional, and will not likely take the place of either of these drugs.

Paraldehyde is a pure hypnotic of great value. It may be regarded as practically free from danger and after ill-effects. Its most objectionable taste and odour are its greatest disadvantages. It may be given in drachm doses for weeks or months at a time, and the dose as a rule does not need to be increased. A paraldehyde habit has been observed to follow its habitual use in a few cases. It is indicated in every form of sleeplessness where pain is absent, and is the most reliable hypnotic in cardiac cases. In pulmonary distress it is inferior to sulphonal. In insanity, paraldehyde has undoubtedly given better results than any other drug except hyoscine, and its new rival, sulphonal, has been compelled to give way before it in the routine treatment of the insomnia of acute mania melancholia, and general paralysis. This is chiefly owing to the fact that the unpleasant nervous symptoms following sulphonal have deterred physicians pressing its administration in doses very much larger than the average, whilst paraldehyde can be fearlessly given in doses of 4 to 6 or more drachms. Thus, Clouston has given it for a fortnight to a general paralytic in doses of 4 drachms. Recovery took place in one case where $3\frac{1}{2}$ ozs. were swallowed in mistake.

It acts with rapidity, sleep lasting about 6 hours, and there are very little unpleasant sensations next day save the most disagreeable odour which it imparts to the breath. This is so obvious to those coming in contact with the patient, that it prevents its general use in simple insomnia.

Urethane is a safe hypnotic, and has been praised by Leech and Gordon as a remedy for mild cases of insomnia. The writer like many others, has ceased to employ it owing to its uncertainty. Even in doses of 100 grains it very often produces no appreciable hypnotic effect. If we had no other harmless hypnotic it might be still urged that it should have further trial, but there is no reason why it should not be permitted to fall into disuse. It has been recommended to give it in combination with Chloral, but Chloralurethane meets this suggestion thoroughly. Hedonal (Methyl-propyl-carbinol Urethane) in doses of 15 to 30 grs. given in cachets has been tried successfully in simple insomnia and in cases of mild mania, and it is like every new hypnotic stated to have no drawbacks.

Hypnone is also a most unreliable hypnotic, and the same verdict may be safely pronounced upon its employment in insomnia, though sometimes it does seem to produce sound sleep. It has a most objectionable odour and taste. It causes so much gastric irritation that it cannot with safety be given, even in the form of capsules (4 minims), without producing pain or vomiting.

Methylal first introduced by Richardson, is a strongly-smelling liquid, causing sleep in doses of about 1 drachm. It is a very expensive and a weak hypnotic, and very often fails. Its sweet taste and rather agreeable odour contrasts favourably with those physical properties of the last-mentioned members of the hypnotic group.

Amylene-Chloral or Dormiol, an oily liquid given in doses of 10 to 40 mins in capsules, has recently been much praised in mania, melancholia, hypochondriasis, and functional neurosis. Amylene Hydrate is a colourless tertiary alcohol, which has been found to produce reliable hypnotic effects in doses of about one drachm. It is best given in claret or any weak wine, and it appears to act like chloral, without exerting dangerous depressant action upon the heart in ordinary doses. It acts very rapidly but its unpleasant taste and expensiveness are barriers to its usefulness, though it has been found to give effects equal to those of paraldehyde in delirium tremens and melancholia. It can be, moreover safely given to children.

Duboisine is a valuable hypnotic, which has lately been found of much value in insanity. It is given in the same dose as hyoscyamine and hyoscyamine, and it is contended by Murrell not to

be a pure alkaloid, but a mixture in uncertain proportions of atropine and hyoscyamine.

Pellotine is an alkaloid obtained from *Anhalonium Williamsii*, which produces sleep in 1 gr. doses, but it is uncertain and liable to be followed by unpleasant after-effects such as vertigo, and it is not likely to come into general use.

Methylene Blue in doses of 1-1½ grs. given by deep injection into the gluteal muscles, or in doses of 4 grs. in capsules, has been very favourably reported upon as a safe mild hypnotic in mania.

Antipyrine and Antifebrin have been credited with hypnotic influence, but where this has followed their administration it has been probably brought about by their valuable analgesic action, sleep following naturally after pain was relieved.

Chloroform and Ether have been used with benefit in exceptional cases of severe insomnia, which resisted other hypnotics, but their use cannot be recommended, and obviously cannot be continued or kept up, even in the most exceptional cases. Ether may be tried in full doses by the mouth where other remedies fail. It is, however, uncertain as an hypnotic, and is liable to produce the ether habit, as seen in the cases of ether tipplers common in some parts of the North of Ireland.

Sumbul, Musk, Camphor, Boldo-glucine, Lupulin, Lettuce, and many other drugs have been used from time to time with little success. When the previously-mentioned hypnotics fail, these latter are useless. *Digitalis* sometimes helps sleeplessness by improving the tone of the cerebral arteries. Nitrites, by reducing arterial pressure when this is too high, as in gouty kidney, &c., may act as true hypnotics.

Hypnotism has been occasionally tried in insomnia. There are cases of inveterate insomnia in the sane, which are occasionally to be met with, and which resist treatment by all hypnotics, owing to the failure of the drugs to induce sleep, or owing to the terrible depression following their action. Static electricity, massage, and the other means enumerated at the commencement of the present article, if tried unsuccessfully, leave nothing but this last-mentioned agent as a last resource. In such cases, if hypnotism succeed even in giving temporary relief, a gain to therapeutics will result, but in its present state of discredit the writer would be slow to sanction its trial in insomnia, except in the hands of those who have given the agent special study and practice.

A method of treating insomnia has been tried by Gautier and Larat. They place upon the patient's head a helmet which bears a small electric motor, which is capable of making about 200 vibrations in a second. The vibrations are conducted through the helmet, and by their steady, monotonous effect produce sound sleep. They claim for this method to cure

insomnia in 8 or 10 *seances* of 10 minutes each given a few hours before bed-time.

INTERMITTENT FEVER.

The treatment for this disease may be summed up in the word—Quinine. Where the therapeutist wishes to point to an example of a 'specific,' he generally finds that the action of quinine in ague leaps at once into his view. When the first symptoms of an attack show themselves, at the very beginning of the cold stage, the important question arises. Can this attack be cut short? Most authorities are satisfied that it cannot, and that, no matter what remedies be used, the disease must take its course, and pass through the cold, hot, and sweating stages.

Nevertheless, there is abundant evidence that the attack may be very materially mitigated or modified in some cases by the prompt employment of remedial agents.

The patient should immediately be put to bed, and hot water bottles and warm clothing freely supplied. Hot drinks or warmed stimulants are useful. Nitrite of Amyl and other nitrites very often stop the chill promptly, but do not appear to influence the succeeding stages. Pilocarpine in a full dose $\frac{1}{2}$ to $\frac{1}{4}$ grain, administered hypodermically at the first onset of the symptoms, has been said in some cases to cause abortion of the attack. To be of any use, however, it must be given at the very commencement of the seizure. Chloroform, internally, in one full dose or one large dose of Opium, has been also found to diminish the duration and intensity of the attack. The hypodermic injection of Morphia often gives great relief at this stage.

Bleeding, purging, blistering, cupping, and emetics have also been found useful but are now seldom if ever employed. Moderate purgation should generally be prescribed, as it undoubtedly increases the efficacy of the remedies to be afterwards given in the later stages.

When the hot stage sets in considerable relief may be obtained by removal of the extra clothing and the free sponging of the skin with cold or tepid water. Cold compresses are grateful. It does not appear that the new antipyretics have been of much use in this stage of the paroxysm.

In the sweating stage gentle friction with hot towels and changes of underclothing may give some relief. After this stage is over, the patient may be permitted to get up and move about.

Whilst there may be considerable difference of opinion regarding the utility of many of the above means being used with the view of aborting or modifying the early stage of the paroxysm, there cannot be a second opinion about the urgent necessity of prompt treatment for preventing the recurrence of the attack.

The researches of Manson, Marchiafava, Golgi, Mannaberg, and others have opened up one of the most remarkable chapters in therapeutics. These observers have watched the amoeboid parasites in their various stages of development in the blood of patients suffering from malarial fevers, and found that the various symptoms corresponded invariably with the developmental changes of the parasites. Mannaberg has closely studied the action of quinine upon them by drawing off and examining minute quantities of blood after the drug had been administered by the mouth or hypodermically. He has proved that the action of quinine upon the malarial amoeba is analogous to its effects upon infusoria, as discovered by Binz many years ago, and which led this brilliant observer to infer that malarial and other fevers were produced by the introduction of amoeboid organisms into the blood. At the period of Binz's experiments (1868) on infusoria malarial fever was then regarded as a neurosis.

In the quartan and ordinary tertian forms Mannaberg found that 3 hours after a dose of about 12 grs. quinine the amoeboid movement diminished, and 4 hours later the number of parasites diminished and those which remained were disintegrated. Baccelli found that most of the parasites had disappeared in 24 hours after quinine had been administered. In the severer forms of fever the drug sometimes fails to cause necrosis of the amoeba, and Mannaberg, in investigating this faulty action, concludes that the method of administration has much to answer for. He maintains that to exert its full action it must be dissolved in the blood in as strong a proportion as possible, and he therefore advises hypodermic injection of the following solution, 15 minims of which will contain nearly 11 grains:—Hydrochloride of Quinine 10 parts, water $7\frac{1}{2}$ parts, dilute Hydrochloric Acid $2\frac{1}{2}$ parts. Baccelli has had great success in the most malignant forms by the intra-venous injection of a solution consisting of Hydrochloride of Quinine 10 parts, Chloride of Sodium $\frac{1}{2}$ part and water 100 parts. Golgi, by studying the state of the parasites at different periods after the administration of quinine, has proved that the drug is of the greatest use in the smallest dose about 3 to 5 hours before the attack. The next attack follows in full severity, but further attacks do not occur, often even when no more of the drug is given. Mannaberg points out that if 15 grs. be given at this period (3-5 hours before the attack), the blood will contain as much quinine as will kill the entire young brood of parasites *in statu nascendi*, and thereby the attack which should follow is rendered impossible. In multiple infections with quartan parasites, Golgi changes a triple quartan (quotidian) first into a double, and finally into a single quartan by killing one generation of parasites after another by giving 6 grs. Quinine 2 hours before the attacks, this kills and removes the new generation represented by the spores formed during the attack. Other authorities, as Dock, advise that the drug should be given between the attacks, and Sydenham recom-

mended that it should be given after the paroxysm. Clinical experience proves that it matters little when the drug be administered, provided that it be administered in such doses as will cause a rapid saturation of the system. The insoluble sulphate should give way to the very soluble hydrochloride.

In the severe summer fevers the Roman plan is to give 15 grs. immediately, and repeat the dose in 2 to 4 hours, and then to give about 15 to 20 grs. every 12 hours. In severer cases one hypodermic injection of 15 to 30 grs. is given at first. Where pernicious symptoms are present one dose of 30 to 45 grs. is given, and 15 grs. every 4 to 6 hours after. In the worst forms the drug must be given by the veins.

The administration of the remedy should be pushed till there is conclusive evidence "that the paroxysms are broken." Afterwards it should be continued in smaller daily doses for some months, till long after the thermometer and the absence of periodical increase of urinary salts have proved that the disease has disappeared. Upon the least sign of a return, it will be advisable to resume the administration of the drug in doses sufficient to produce cinchonism.

Though hosts of ague specifics have been recommended, it is rarely necessary to resort to any drug but Quinine, which in the great majority of cases cuts short the disease with rapidity and certainty. In malignant cases one is not justified in trusting to any other agent, as time is an important element in the case, and death may supervene before any other remedy has time to act. Amongst the drugs found to possess marked antiperiodic powers next to Quinine stands Arsenic. It is sometimes found to cure when Quinine has failed, and this is especially true if the ague is of the quartan type, or if it has been of long standing. 5 minims of Fowler's Solution may be given three times a day. It may be combined with Quinine in the treatment of the malarial cachexia. Cacodylate of Soda will probably prove the best form for the administration of arsenic.

Decoction of fresh unpeeled Lemons has been proved to possess valuable anti-malarial properties, and may be given freely, alone, or in conjunction with Quinine.

Ferreira and others have published excellent results from Methylene Blue, and they state that the parasites disappear from the blood under its use. It may be given to children with advantage in small capsules containing $\frac{1}{4}$ grains every three or four hours.

Iwanoff gave 5 grs. three times a day in tertian ague, and found that the protoplasm was markedly affected in the adult stages.

Warburg's Tincture possesses powerful diaphoretic and antiperiodic properties, and is highly praised by M'clelan. (See Author's Manual of "Materna Medica and Therapeutics," 7th Edition, page 604.) The dictum of Osler may be here quoted to

show the uselessness of printing the list of drugs which have been vaunted as remedies for malarial fever :—" The physician who at this day cannot treat malarial fevers successfully with Quinine should abandon the practice of medicine."

Quinine possesses also great prophylactic power, and 5 or 8 grains daily will generally be found to afford protection in bad malarious districts.

The after consequences of ague or the malarial cachexia will be best treated by removal from the malarious district, and the steady administration of Arsenic and Iron, and the occasional use of Quinine. Maclean strongly recommends a sea voyage, and a sojourn at the baths of Carlsbad or Homburg. The enlarged spleen gives way to large doses of Quinine and Iodide of Potassium, and to local applications of Bimiodide of Mercury Ointment, or of Lin. Pot. Iod. cum Sapone.

It is needless to dwell upon the value of drainage and cultivation of marshy land by planting eucalyptus trees, &c., as preventive measures. The discovery of Manson that the disease is propagated by the mosquito (*Anopheles*) demonstrates the necessity of destroying the larvæ in all collections of stagnant water near to human dwellings. This can be done in many instances by pouring a little paraffin oil over the surface, the minute film effectually asphyxiating the larval form of the parasite. In large tracts of water the introduction of fish has been followed by much permanent benefit. An elevated sleeping ground with the use of mosquito-netting is essential. Manson's experiment on the Roman Campagna, where five persons slept in a mosquito proof hut for four months, exposing themselves freely all the day without becoming malarious, whilst all those about them suffered from the disease, is a striking practical demonstration.

INTERTRIGO.

The treatment applicable to Acute Eczema (page 250) will speedily remedy this affection. As it occurs about the flexures of joints, or where overhanging or overlapping folds of integument are permitted to remain in contact, it will generally be necessary to separate the opposing surfaces by a fold of lint or absorbent wool smeared over with Zinc Ointment, or freely sprinkled with Fuller's Earth, Zinc Oxide, Bismuth Carbonate, or other drying powder, to which a little finely pulverised Camphor has been added. As a rule, pastes, powders, or stiff ointments are very much better than lotions. The following is a good ointment :—

R. Unguent. Zinci ℥ii
 Bismuthi Carbon. ℥i
 Calamina Præpar. ℥i.
 Spir. Camphoræ ℥i. misce

Tere bene et fiat unguentum

Morris recommends that the overlapping surfaces be kept apart by mushin bags filled with starch and boric acid.

This subject is also discussed under Erythema Intertrigo (page 296).

INTESTINAL HÆMORRHAGE—See Melæna.

INTESTINAL INFLAMMATION—See Enteritis.

INTESTINAL OBSTRUCTION.

No more serious problem can be presented to the mind of the physician than that involved in the treatment of a case of acute intestinal obstruction. Year by year operative measures are becoming more generally recognised as an early indication instead of being regarded in the light of a *dernier resort*, as has been the case in the past. Already there are not wanting signs that the pendulum has swung too far in this direction, some authorities recommending an immediate resort to laparotomy without waiting for any trial of the older therapeutic agents. The natural tendency, doubtless, is to wait too long before resorting to abdominal section, and hence it is perhaps an advantage that the earliest adoption of operative measures should be put in the most forcible light possible. The natural reluctance to such a serious undertaking will probably always prevent the operation being performed before opium, enemata, &c., have obtained a trial though these measures probably will cease to be pushed so far as to render operative interference too late.

The first step in arriving at a conclusion regarding the ~~best~~ treatment is to make as accurate a diagnosis of the ~~cause~~ of the obstruction as the difficult unravelling of the tangled web of the symptoms will permit. In those cases where a positive diagnosis is possible, the difficulty of deciding upon the most appropriate treatment is not great. No decision for or against operation should be arrived at till the physician has exhausted every means of coming to a conclusion as to the case being one of volvulus, intussusception, strangulation by bands or apertures, &c., stricture, fecal accumulation, or tumours. Unfortunately it is not within the scope of the present volume to discuss the various symptoms which enable the physician or surgeon to differentiate these various causes of intestinal obstruction.

In the great majority of cases it is impossible to arrive at any conclusion till the symptoms have been watched for a short time; indeed, it is impossible to be certain that the case is one of mechanical obstruction till a certain time has passed over. During this period the lines of treatment are clear. Absolute rest in the horizontal position in bed with the knees drawn up as the patient lies upon his back is the easiest position, and the one naturally assumed during the later stages. As vomiting is an early symptom, little nourishment can be retained, and efforts at forcing it into the stomach are worse than useless.

Hot water in small quantities, or hot weak tea, is the most that should be permitted. The old practice of administering ice is now universally condemned. Nutrient enemata may be tried with benefit in a few cases.

Opium is of service, and is to be given in proportion to the amount of pain present. The smallest quantity which will give relief to pain is the dose to be administered. There is, however, one serious objection to it, but which, nevertheless cannot be permitted to forbid its use—*i.e.*, it tends to mask the symptoms, and may mislead. The experienced physician will constantly have to make allowance for this, and have it ever before his mind in weighing the serious issues as the case advances. The opium should be given as the case may indicate. Thus, in violent sudden pain, soon followed by vomiting, the hypodermic injection of $\frac{1}{4}$ grain of Morphia, or an enema containing 45 minims of Laudanum, should be given. As a rule, solid opium, or the powdered preparation made into pills, should not be administered owing to the retardation of absorption.

30 minims of the solution of Morphia, with 1 minim of Atropine solution, can be safely given by the mouth, and half these quantities may be repeated every 2, 3, or 4 hours, as the pain and collapse warrant.

Treves prefers Morphia alone, and condemns the addition of Atropine, which he considers increases the sensation of thirst, always such a troublesome symptom in cases of obstruction.

Chloroform or Ether should not be employed at this stage, as the vomiting which often follows their inhalation may seriously mislead the physician, and aggravate the patient's suffering.

Hot poultices of linseed meal, or cold compresses or ice bags, according to the patient's sensations of comfort, may be applied over the entire abdominal surface. Bryant lays great stress upon the value of Belladonna externally as a means of quieting peristalsis. He also gives the drug internally by the mouth or as a suppository, and prefers it to opium. He records some interesting successes from treatment which might be thus summed up.—The recumbent position, with elevation of the pelvis, so as to allow gravity to act towards the thorax, starvation, rectal feeding, Belladonna and Glycerin externally, and Belladonna and Opium internally.

If a purgative has not already been administered, which is too frequently the case, the physician should not only abstain from prescribing it, but he should warn the patient and his friends of the danger of attempting to have the bowels moved by this means. Even when the case is strongly suspected to be one arising from fecal accumulation, purgation is fraught with very considerable danger at this stage of the obstruction.

Enemata may, however, be administered with comparative safety, and occasionally with benefit. To do so to best advantage requires attention to several important details.—The patient

should be turned over upon his left side, the shoulders should be lowered, and a hard pillow or cushion placed under the pelvis, so as to favour the gravitation of the fluid along the colon.

The syphon apparatus is preferable to the India-rubber suction or the old-fashioned piston appliance. Should these latter be employed, the greatest gentleness and patience must be exercised, so as to prevent premature reflex contractions of the colon or rectum. Tepid water alone, without soap, Castor Oil, Turpentine Soda or other irritant, is the best—the object being to throw up as much liquid as possible, without causing its return by stimulating the bowel. This may be assisted in some cases by turning over the patient upon his back, and afterwards upon his right side, so as to assist the passage of the fluid towards the ileo-cæcal valve. At a later stage this object may be favoured by the abdominal taxis.

The administration of the enema should not be entrusted to any other hands, but should be carried out by the attendant himself. By pausing occasionally during the operation (without removing the tube) till the temporary spasm of the bowel subsides, large quantities of fluid may be introduced.

The writer believes that the use of O'Heirne's long tube is a serious mistake; he has never seen any advantage from it, but, on the contrary, he has witnessed mischievous irritation produced by its use. The enema may afford considerable relief by ridding the colon of its contents; it may dislodge an intraction, unfold a twist, or even remedy an invagination. It is also, in some cases, of great value in clearing up a diagnosis, and if given with the care just now recommended is very unlikely to do any mischief.

Treves rightly protests against the practice of the administration of repeated enemata in acute obstruction. He points out that the object is not to relieve the strangulation, but simply to empty the colon, and remarks that if the first injection is not successful, subsequent attempts are not likely to be more so.

When the symptoms of acute obstruction show no signs of yielding to starvation, rest, opium, local applications, and a copious enema, there are still other measures which have been recommended. Jonathan Hutchinson has advocated vigorous massage, and shaking and kneading of the abdominal contents after the patient has been thoroughly anaesthetised. He has applied the name of abdominal taxis to this procedure, and some successful cases have been recorded, but modern surgeons give their opinion in favour of more precise methods, and abdominal taxis is now rarely employed, and is certain to fall into total disuse.

Tapping. The distended loop, the seat of volvulus, or of constriction by a band, may be tapped by a fine trochar and canula thrust through the abdominal wall. The spontaneous reduction of the strangulated coil has been known to follow the withdrawal of the gas. It is not admissible, however, where there is reason to believe that the coats of the bowel are seriously diseased or inflamed.

Where intussusception has been diagnosed, and copious warm water enemata have been tried in vain, the bowel may be distended by pumping in air through the rectum by means of a pair of bellows, a Higginson's syringe, or an instrument devised for this purpose. Sulphuretted Hydrogen or pure hydrogen has been similarly used.

Carbonic Acid has been successfully employed in some cases. It can be generated in the bowel by injecting a solution of Bicarbonate of Soda, followed by a solution of Tartaric Acid; or siphons of the gas may be used conveniently. The inflation of the bowel by the bellows is more satisfactory, as the amount of air required may be measured to a certain extent by the resistance and by the tension of the walls of the abdomen. Many cases have been cured by these means, but the practice is not without serious danger, as the pressure may, especially in infants, cause rupture of the bowel, and there is some likelihood of the intussusception being only partially relieved or reduced, in which case the symptoms return with intensity after a temporary amelioration. Barker has published several cases where the intussusception appeared to be reduced, but where the symptoms returned. He strongly advocates operation after a fair trial of enemata when the case is seen early, and he records several successes.

Inflation is not only useless, but is distinctly contra-indicated where the invagination is of long standing, or where there is evidence of acute general peritonitis, gangrene, or adhesions.

Metallic Mercury has been administered. The writer knew of one case of obstruction from intussusception where more than three pounds avoirdupois of the liquid metal was administered by pouring it through a funnel and tube into the stomach. Though the obstruction was relieved, the patient died several weeks afterwards from what was supposed to be the result of an indiscretion in diet. It is not, however, a method to be recommended, being very liable to destroy the bowel or cause serious trouble by its retention afterwards. It has, however, been employed occasionally in fecal obstructions successfully. Notnagel still recommends its use as harmless in recent cases, but Erichsen describes it as an ancient and barbarous method.

Where a very large impacted gall stone causes symptoms of acute obstruction from blocking up of the small intestine, rest, Opium, and abdominal massage have been followed in several cases with success.

Electricity.—The application of a strong interrupted current to the abdominal walls has been known to relieve symptoms of acute obstruction, and some physicians recommend the introduction of one pole into the rectum. The best method of using electricity for this purpose is to use a strong continuous current. Boudet makes a Solution of Salt injected into the rectum to act as one electrode. He passes a current of 40 milliamperes for 5 minutes, after which he reverses it and interrupts it every 20

seconds. Excellent results are reported after this treatment, but in an internal strangulation it is liable to do serious harm.

Washing out of the stomach may give considerable relief, and may be resorted to, pending the completion of arrangements for a more serious operative interference. It is indicated where the vomiting is distinctly stercoraceous, it is always palliative, and may possibly be curative. Rectal feeding by nutritious or peptonized enemata, may be called for where vomiting is incessant and collapse well marked.

Where success does not immediately follow the employment of the various measures already described the operation of laparotomy should be decided upon without further delay. The writer can recall vividly many cases in his own experience where the post-mortem revelations, or the knowledge acquired in later years, would justify him in saying that had laparotomy been performed it would have probably saved life. The practice of opening the abdomen in such cases dates back from a comparatively recent period, yet innumerable lives have been saved from it during the last ten or twelve years. The high mortality is sure to yield when, by common consent, the operation is undertaken at an earlier stage of the disease. Delay is dangerous every hour increasing the chances of a fatal termination, though Sir B. W. Richardson maintained that laparotomy need not be seriously entertained till the onset of fecal vomiting, after which it is imperative. Hutchinson does not recommend laparotomy, he believes it is seldom successful and he fears that if the rule of operating very early be adopted the mortality will be greatly increased. This is not a question for a hard and fast line as soon as the symptoms demonstrate a mechanical obstruction the surgeon should think and act as he would do in a case of strangulated hernia. Basing his opinions on his own experience and on a series of tables published by leading surgeons Treves estimates the mortality after operation in acute obstruction as 50 per cent, and expresses the conviction that this mortality will be still further reduced when the necessity for early operation is more widely appreciated.

McArdle has recorded 41 operations for acute obstruction, with 34 recoveries.

The abdomen should be opened in the middle line between the umbilicus and pubes. There is no advantage in making a very free incision as the object of the surgeon is to prevent the protrusion of the intestines. A wound sufficiently large to admit three fingers is generally sufficient. In the case of intussusception in children, it may be well to attempt exploration through an incision large enough to freely admit two fingers. Further extension of the opening can be easily made afterwards, if necessary.

In those cases where laparotomy is undertaken for obstruction which a previous herniotomy has not relieved, or where the case is complicated by the presence of an old hernial sac or scrotal tumour

of doubtful contents, it is, notwithstanding the advice of eminent authorities, better to make a fresh median incision than to cut down upon the neck of the tumour, or prolong inguinal incisions previously made. The writer has assisted at four operations where abdominal incisions were extended from the region of Poupart's ligament or the inguinal canal, and the subsequent steps were most seriously complicated thereby. The median incision would have saved life in one of these cases.

Greig Smith lays great stress upon the dangers and disadvantages of anesthetics in operating for abdominal obstruction. He states that the anæsthetic increases shock where such increase can ill be borne, and that it has a special risk of its own as tending to induce vomiting, which may suffocate the patient. The distended stomach should be emptied by passing the stomach tube before anæsthesia is begun, or, at least, before it is complete. The anæsthesia should be continued no longer than is necessary to make the parietal incision, and place the sutures ready for tying—that is to say, from 3 to 5 minutes. All further manipulations may be carried out without pain to the patient while he is recovering from the anæsthetic. It is wonderful how little these patients feel and how quietly they will lie and languidly watch the proceedings being carried out for their relief.

The abdomen being opened under aseptic precautions, and the intestines prevented from protrusion by the application of warmed aseptic sponges or flannel cloths, the surgeon should insert his hand and make, in a bee-line, for the ileo-cæcal valve. Should there be much difficulty in doing so, the distended coils of intestine may be freely punctured with a fine trochar, though it is often surprising to find in some cases how little additional room is gained by this procedure. The circum being found in a distended condition, the surgeon knows that he will come upon an obstruction in the large intestine by following the course of the bowel from the valve towards the rectum. Where there is any great difficulty in doing this he may begin anew at the upper part of the rectum, and proceed upwards in the direction of the transverse colon and valve pursuing his exploration methodically and leisurely till he arrives at the seat of obstruction. Upon the same principle the small intestines are to be explored, passing each portion rapidly through his fingers. If a band or diverticulum is found to be the cause of the strangulation it is to be divided and the imprisoned coil or knuckle of bowel set free, an internal hernia may be reduced and an intussusception drawn out gently, squeezing or kneading the lower portion from below upwards. Where reduction of the invagination is found to be impossible, enterectomy should be performed, and this is also applicable where gangrene has supervened. When the obstruction cannot be discovered, the most prominent coil of distended bowel should be sutured to the abdominal wound, and an artificial anus then produced.

Kocher and many others hold that the cause of death in most cases is septic intoxication, the toxins being absorbed from the congested and distended bowel above the stricture. They insist on opening and emptying of this bowel as an essential part of every laparotomy for obstruction.

Obstructions caused by gall stones or foreign bodies are to be dealt with by incising the bowel, and suturing the wound with catgut and returning it.

Strictures are best treated by enterectomy, and when situated in the large intestine must be met by colotomy or colectomy.

Volvulus of the sigmoid flexure may be best treated by incising and emptying the distended loop, after which it is occasionally possible to reduce the twist, when the bowel may be sutured and returned. Failing reduction, the opening in the bowel is utilised for the formation of an artificial anus. When failure attends all other means of relieving fecal accumulations, colotomy may be entertained as a means of giving relief. This should, however, be avoided till the prolonged use of copious enemata, cautious attempts at purgation, and the supervention of urgent symptoms, prove that further delay is useless.

The treatment of the *chronic* forms of intestinal obstruction, or of the acute forms supervening upon the chronic is to be carried out upon the same general principles as those already mentioned. Preventive or palliative treatment by judicious dieting* must not be forgotten, and the physician should not be tempted to postpone laparotomy till the supervention of perforation or general peritonitis renders its success almost hopeless. Nelaton's operation or enterotomy, whereby an artificial anus may be established in the small intestine, is indicated in those cases where the seat of obstruction is beyond reach. It may be performed by making an incision above Poupart's ligament upon the right side. After entering the abdominal cavity the first coil of distended bowel presenting in the wound is sutured to the margins of the skin incision by a double row of sutures, after which the bowel is freely opened between the sutures.

Greig Smith, in speaking of those cases where there is great difficulty in finding the cause or seat of the obstruction, says:— "I think it wiser at once to perform enterostomy than to spend much time groping about for the cause of the obstruction. The fact that enterostomy or abdominal drainage will, even if the cause of the obstruction has not been touched, rescue a patient from death, is sufficiently well established to want no emphasising from me."

The after-treatment is to be carried out upon general principles as in the case of herniotomy.

* The treatment for coins, false teeth, plum stones, and foreign bodies which have been accidentally swallowed, should be carried out by feeding the patient upon a constipating diet, as dry fresh bread, hard-boiled eggs, &c., with the view of entangling the foreign body and causing it to be safely carried to the anus. Purgatives must not be employed, as the liquid contents may be thus swept past the substance.

INTUSSUSCEPTION—See preceding article on Intestinal Obstruction.

IRITIS.

The first thing to do is to administer a smart saline purge, and drop into the eye a few drops of the B.P. Solution of Sulphate of Atropine. Pain, which is generally a prominent symptom, may be allayed by hot, dry compresses, by hot stuping, or by adding Cocaine to the atropine drops. If all other means fail, hypodermic injections of Morphia may be required. In acute cases the patient should be kept in a darkened room, or if this is not feasible, he should wear dark goggles. When there is much congestion, three or four leeches applied to the margin of the orbit or temple give great relief. As a rule, if wide and uniform dilatation follows the use of atropine, the case will soon yield. If there be much plastic exudation, and the atropine fails to enlarge the pupil widely, it must be pushed, a drop being instilled every five or ten minutes for six times with the view of dragging upon the adhesions. If this fails, the eye may be covered for the night with a piece of lint, smeared with atropine ointment. Mercury should be freely given in all cases where this result is not speedily obtained. In syphilitic cases the action of the mercury must be kept up till there is evidence that the constitutional effects of the drug have been produced, after which the dose may be diminished. Salivation is seldom necessary, and should be avoided. Mercury is essential in all cases of iritis with much exudation of lymph, but in non-specific cases its action may be suspended as soon as this disappears. The influence of atropine should be maintained till it is clear that the danger of adhesions has passed away.

In serous iritis, if a deposit forms on the posterior surface of the cornea, it is sometimes recommended to tap the anterior chamber by inserting a fine cataract knife into it in front of the iris, and this may be repeated if the fluid accumulates again.

With a distinct rheumatic history, Salicylate of Soda may be given in full doses, also where mercury is indicated but cannot be tolerated. Good results have lately been reported from the use of Aspirin.

Turpentine in full doses internally (10 minims every 4 hours) has been proved to possess remarkable power in causing absorption of exudations. Duboisine, Pilocarpine, Cocaine, Homatropine, and Physostigmine have been recommended, but the general management of a case of ordinary iritis may be summed up in the words—Rest, Atropine, and Mercury.

When the rapid increase of the plastic exudation threatens to close up the pupil, it may be necessary to speedily produce the constitutional effects of mercury byunction in severe cases.

Good results have been obtained by injecting about $\frac{1}{4}$ gr. Calomel, suspended in Glycerin or weak Mucilage, into the tissues in the neighbourhood of the margin of the orbit.

The treatment of suppurative iritis and of irido-choroiditis is to be carried out upon the same lines as in severe iritis, the intense pain being relieved by Cocaine, and Morphia hypodermically.

Sympathetic iritis must be promptly met by enucleation of the primarily affected eye and the frequent instillation of a weak Sublimate Solution into the secondarily affected eye.

Where, in spite of atropine and mercury, or where the case has been neglected from the first, and adhesions have formed which refuse to yield to atropine they may require to be treated by operative measures. Tearing them down with a hook has not proved satisfactory, but if they are extensive and keep up a chronic irritation in the eye, iridectomy should be done.

ITOH—See Soablen.

JAUNDICE.

The treatment of jaundice cannot properly be detailed here. It is but a symptom of a large number of totally distinct affections and the most appropriate management of these will be given under their separate headings. (See Gall Stones, &c.) For the jaundice itself there cannot be said to be any specific treatment, but there are, fortunately, remedial agents of value which may be palliative, even when the cause of the jaundice is irremovable, as in cancer, tumours, impacted calculi, &c. The first object of the physician, then, is to treat the cause. This is very often, for example owing to a catarrhal condition of the stomach, the inflammation creeping from the gastric mucous membrane into the duodenum and up the bile duct. As already described, this condition soon yields to appropriate remedies, such as mild purgatives, judicious diet, Bismuth and Alkalies, with minute doses of Morphia and Counter-irritation.

There have been few more interesting or puzzling problems in medicine than the causation of jaundice in those cases where the large ducts are free from obstruction. The old theory of a purely toxicogenous jaundice independent of hepatic causes, and the older theory of suppression as well as the views about increased secretion and deranged innervation appear to be all requiring serious modification in the light of the recent researches of Wm. Hunter. This observer maintains that the cause of jaundice in these so-called non-obstructive cases depends upon toxæmic changes which whilst altering the blood, invariably produce such changes in the small ducts and increased viscosity of the bile as to cause obstruction beginning above. In this view all jaundice is obstructive.

At present we know of few drugs which stimulate the liver to increase the secretion of bile, though Salicylate of Soda is said to have this effect.

It is therefore, arises—Is there any safe efficacious treatment for trial in those instances of "simple" jaundice,

i.e., those not depending upon obvious obstruction of the large ducts? Search should always be made for the presence of some poison, either introduced from without, as phosphorus, arseniuretted hydrogen, yellow or other fever, or for some toxin produced in the intestines.

Various agents have enjoyed some reputation as empiric remedies in simple jaundice.

Any attempt to treat a symptom of this complex kind, about whose pathology there is so much uncertainty, is open to the imputation of quackery, and, as Duckworth has put it "the recommendations of any drug for the treatment of a symptom depending upon so many possible causes can hardly receive serious attention unless a full diagnosis of the cases has been established." Where, however, a full diagnosis is impossible, and where upon no other grounds than mere empiricism a certain drug has been used and found by some observers to produce good results, there can be no valid reason why it should not receive serious attention, especially if it be free from the objection of being dangerous or harmful.

Of remedies of this class the common Ragweed (*Senecio Jacobæ*), recommended by the late Dr. Charles Pardon, is a typical example. He found that tea-spoonful doses of the liquid extract (1 in 1) had a marked influence in dissipating the jaundice.

Vichy and Carlsbad waters on the Continent, Podophyllin, Euonymin, and Iridin in small doses in America, and Alkaline Soda, Potash and Ammonia Salts at home, have long been maintained to exert decidedly beneficial action in simple jaundice. The following combination is often prescribed:—

R. *Sodæ Bicarbonatis* ℥iss.
 Pulv. Rhei Radicis ℥ii.
 Pulv. Zingiberis ℥iv.
 Pulv. Calumbæ ℥vi.
 Pulv. Ipecacuanhæ Co. ℥i. misce

Fiat pulvis. Signa—"A small tea-spoonful in half a tumblerful of Polish water, to be taken every four or six hours"

The following liquid preparation may be used:—

R. *Succi Taraxaci* ℥i.
 Sodæ Salicyl. ℥iv.
 Tincturæ Rhei Co. ℥iss.
 Infus. Gentianæ ad ℥xii. misce.

Fiat mistura, cupus capiat cochleare magnum ter in die.

Where alkaline agents are not admissible, benefit may be derived from the favourite acid remedy—Dilute Nitro-hydrochloric. This

may be given in doses of 20 minims, well diluted with a weak bitter infusion, three times a day, before meals; and 25 grs. of the Chloride of Ammonium may be given at bed-time in warm whey. The diluted acid may be also applied locally, or used as a bath.

Calomel and other mercurials should not be employed in simple jaundice except as occasional purgatives, when they may be followed by a morning draught of Friedrichshall water, Sulphate of Magnesia, Sulphates of Potash or Soda, Phosphate of Soda, or Carlsbad Salt. Enemata of cold or tepid water may be employed daily. Turpentine in full doses has been loudly praised.

The value of Pilocarpine will be presently referred to. Quinine and Arsenic may be found useful in cases of malarial jaundice.

The diet should be as simple as possible. A skim-milk diet the writer believes to be the best in such cases. Sugar, fats, and alcoholic stimulants should be avoided. Butcher's meat is best given in the form of beef tea or clear soup. Rice and other farinaceous foods may be allowed. Hot baths and hydropathy, as will be mentioned, are valuable aids to treatment.

There may be legitimate doubts expressed about the value of the above-named agents in dissipating simple jaundice. They possess one advantage, however—that used as recommended they can do no harm.

In *malignant* jaundice Arnozan, upon the parasitic theory of the disease, has successfully treated it with antiseptics. He injects morning and evening hypodermically in water $\frac{1}{2}$ anuum Carbolic Acid, and administers by the mouth 20 grs. each of B-Naphthol, Quinine, and Charcoal, in catchets during the 24 hours.

Where the symptoms indicate the presence of gall stones, the various measures mentioned upon page 305 should be pressed into service, and when the obstruction is complete, operative interference may be the only remedy available.

When permanent jaundice has been established, or where there is evidence that the icterus is dependent upon obstruction, the most that can be done is to assist nature in her efforts to eliminate the re-absorbed bile. There can be no question that substances supposed to be capable of exerting a marked effect upon the liver or duodenum, as full doses of Calomel, Podophyllin, Soda Salts, or Evonymin, are generally contra-indicated in these cases. Purgatives are required, but only such as exert no well-marked hepatic action should be selected. Salines are the best, and they may be preceded by Aloes or other cathartic of the same class.

In this way the natural purgative effect of the bile, which in the normal condition flows into the intestines, may be kept up, and portal congestion at the same time will be diminished.

The bile, however, exercises important functions in health, assisting the absorption of fats, and preventing fermentative and putrefactive changes occurring in the intestinal contents. It is, therefore, advisable to supply a substitute as near as possible to the natural fluid in chemical constitution. In the official Fel

Bovinum Purificatum this is obtained. It is, however, so seldom employed, that when ordered by the physician an old effete sample is likely to be supplied by the chemist. 10 grs. of the fresh preparation in pills, may be administered three or four times a day before food, or as Yeo suggests, the pills may be coated with keratine, so that their passage unchanged through the stomach may be secured.

Where the absence of the natural bile has led to diarrhoea, resulting from the irritation of decomposed or putrefying intestinal products, the best thing to do is to administer an intestinal disinfectant. The best is Turpentine, given in large doses, in the form of a capsule, which, if swallowed when the stomach is quite empty, may be found to pass directly through into the intestines, where it will exert its antiseptic properties to best advantage. Creosote may be given in the same way, or Charcoal also in the form of capsule. Naphthalin or other antiseptic may be employed.

As the bile is chiefly eliminated by the kidneys in obstructive jaundice, diuretics, as copious draughts of warm liquids, or even members of the stimulating diuretic class, as Broom, Digitalis, Iodides, &c., may be employed with much advantage. The skin should be kept in the best condition by wearing warm clothing, and resorting to the warm, hot, or Turkish bath, or by using a hot or wet pack every evening.

There is one very important drug which may be used with much advantage in jaundice from obstruction. It relieves the distressing itching of the skin after warm Alkaline baths have failed. *Pilocarpine*, administered hypodermically, in doses of about $\frac{1}{2}$ grain, relieves this distressing symptom for 24 or 36 hours; it is in fact, the only remedy for this purpose on which much reliance need be placed. It was urged to be a specific for all cases of simple hepatogenous jaundice, but it has failed to sustain the high expectations raised by the early reports. Nevertheless, it often gives excellent results.

Gerhardt's method of treating all cases of catarrhal jaundice in children and adults is a good one. It may be useful in the obstruction caused by small calculi, and is carried out by passing a smart Faradic current through the gall-bladder, by placing one pole over the spine and the other over the distended organ, so as to produce brisk contraction of the muscular fibres of the gall-bladder.

The treatment of infantile jaundice is most unsatisfactory. The ordinary icteroid tinge appearing upon the skin of children a few days after birth is, however, hardly worth mentioning. It is probably caused by the habit of half smothering up all new-born infants in flannels. It rapidly disappears upon the administration of a purgative, and a liberal supply of fresh air.

In cases where jaundice supervenes before birth, or comes on with deep conjunctival staining soon afterwards, no remedy appears.

to stop the commonly fatal issue. The writer has seen an instance where about 10 infants of one healthy mother perished in this way. He did not try Pilocarpine in any of the cases, as its action was then unknown but it would not likely have been efficacious, as in one instance there was congenital absence of the gall bladder though in a subsequent birth there was no malformation, though the infant died 24 hours after being born deeply jaundiced.

JOINT DISEASE.

In detailing the treatment of hip-joint disease the principles which should guide the surgeon have been enumerated. They may be briefly stated in a general way as applicable to the treatment of most joint affections. Inflammation of the synovial membrane will be mentioned under Synovitis.

The first lookout in dealing with a case of chronic joint affection (articular ostitis) in its earliest stages, is to improve the standard of health in every way possible, by pure air, good food, healthy surroundings, and the use of constitutional aids to improve nutrition as Cod Liver Oil, Malt Extract, and Peptonized foods, &c. Where any general tendency to struma, syphilis, rheumatism, or other blood condition prevails, appropriate remedies should be exhibited. In all cases Iron, Iodides, Arsenic, Phosphates, Quinine or other tonics should be given in the early stage of the affection.

Rest is essential it should be as thorough as circumstances will permit; *absolute rest* of the affected joint must be aimed at, though it will not be often attained. It may be attempted in various ways. If the joint be a large one—hip, knee, or ankle—the patient should be confined to bed till the acute symptoms pass off, after which locomotion may be permitted when immobility has been secured by means of proper splints or unyielding encasements. This rest must be pushed till all heat, redness and pain disappear. The mistake of keeping a joint too long in a state of absolute repose is a serious one. Ankylosis may result and this termination though undesirable, and to a certain extent unsatisfactory, is one that the surgeon may be glad to hope for in bad cases. The joint, therefore should be placed at the very start in such a position that, should ankylosis occur, the subsequent usefulness of the limb will be the least interfered with.

Where pain is prominent, and does not yield to rest, warm fomentations, hot poultices, cold compresses, evaporating lotions, Leiter's tubes, or ice may be employed, the selection depending chiefly upon the patient's sensations of relief as either application is made. As a routine method, nothing surpasses the old-fashioned method of soaking narrow strips of lint in Spirit Lotion (Spt. V Rect. 1 and Water 2) enveloping the joint with them, and covering all over with a layer of oiled silk, gutta-percha tissue, or thin mackintosh. It is applicable to the most acute and to the most chronic cases where pain is prominent.

Where there is much throbbing pain and congestion, the application of leeches gives much relief. Like cold, leeching is contra-indicated in very chronic cases, except when the patient is suffering acute pain from the supervention of active mischief in a joint long affected with articular trouble.

The use of the actual cautery, applied at intervals of 3 or 4 days, is often followed by striking relief of pain and stiffness.

Extension by means of weights and a pulley as described under hip-joint disease, or by means of suitable splints in the case of other joints, is a valuable means of diminishing inter-articular pressure, though it doubtless exercises beneficial action in other ways.

When the more acute symptoms have been thus combated, and all pain has disappeared for a time, passive motion may be carefully commenced, the surgeon feeling his way cautiously. Many joints have been hopelessly destroyed by rest prolonged long after the inflammatory action had subsided. It is this mistake which enables the unscrupulous bone-setter to thrive. Getting a chronic joint affection in which all inflammatory action has long ceased, owing to treatment by some surgeon whose timidity prevents him beginning passive or forcible movements the bone-setter pronounces the limb to be "out of joint," and after a few forcible movements he assures the patient that he has "put in" the joint, and the mobility and painlessness of the limb which follow apparently corroborate his statements. When the value of early massage and movements of a passive or forcible nature are universally appreciated, the principal occupation of the bone-setter will be gone.

When there is much thickening from exuded inflammatory products outside the joint or effusion into the synovial sac pressure by neatly-applied strapping or Scott's dressing is of much use. A Martin's elastic bandage or massage may succeed when these fail to cause absorption.

Abscesses should be freely opened as soon as the physical signs clearly point to the presence of pus. Where deep-seated pain, limited to a very small area, has been continuous for a considerable period the surgeon need not wait for pointing, but may cut down upon the spot and remove any piece of dead or suspicious bone by a small gouge. Trephining may be resorted to in some cases with excellent results where the localised mischief can be reached without opening the joint. Sinuses may be divided and scraped, and afterwards swabbed with strong solution of Chloride of Zinc, and the small cavities of necrosed bone may be touched with strong Sulphuric Acid.

When it is evident that the joint has become disorganised it may be freely incised and washed out with an antiseptic solution, free drainage being provided by the introduction of moderately sized tubes. This is a fairly satisfactory operation in cases of simple suppuration of a large or small joint, but it gives very poor

results in chronic articular osteitis. The method of opening and thoroughly scraping out the interior of the joint, by which every scrap of diseased tissue is thereby removed, is in many respects to be preferred to excision. This operation, known under the name of Arthrectomy or Erasion of a joint, has materially limited the necessity for excision. It is not applicable to the hip articulation owing to its shape and structure, but in the knee excellent results may be anticipated from this modification of conservative surgery (See under Knee-Joint Disease.)

Where erasion is not suitable—i.e., in those chronic joint affections where the mischief extends for some distance into the ends of the bones entering into the joint, a modified excision or a combination of erasion and excision may be tried. When these means are not admissible, owing to the extensiveness of the disease, there is no resource left but to amputate.

The late method recommended by Koch for the treatment of joint disease depending upon tuberculosis will be found detailed under the article Tuberculosis, and Lannelongue's newer method of attacking the bacilli by deep injections of Chloride of Zinc will also be found there.

For the methods of Biltroth and Bruns of treating chronic suppurating joints by the injection of Iodoform see under Abscess, page 15.

Bier's method consists in the application of an elastic bandage to the limb, so as to bring about passive congestion of the affected joint; the bandage is applied lightly below and above the joint which is left uncovered itself. Barker and others report excellent results obtained in this way.

St. Germain's method of dealing with tubercular arthritis consists in injecting into the joint a hypodermic syringe of the following Copper Phosphate solution, and sealing the wound with collodion. He dissolves 5 parts of crystallised sodium phosphate in 20 of glycerin and 20 of water. This is then mixed and thoroughly shaken up before injecting with a solution of copper acetate 1 part in glycerin 20 parts, and water 20 parts. Considerable fever follows. The dry heat plan of treating old rheumatic joint affections has been tried in tubercular cases, but the results are not yet decisive. It consists in enveloping the joint or limb in a cylinder in which it is exposed to dry air at a temperature of 250° to 300° F. It has been tried by Collier and Willett in rheumatic arthritis and tubercular disease of the knee joint with promising results.

JOINTS, Inflammation of—See Synovitis.

KELOID.

Two distinct affections are embraced under this name. Unfortunately for the present purpose this confusion is of little moment, since each is almost equally beyond the range of remedial

measures, though both may spontaneously resolve and disappear.

Extirpation of the hardened patches or tumours is generally followed by return in a more active form. Where the affected part can be covered with an unirritating plaster, as the Eup. Adhesivum or Eup. Hydrargyri, and protected from all sources of irritation or annoyance, fair results may be obtained. Vidal's method of deep scarification has, when frequently repeated, led to good results, and it may be alternated with Electrolysis.

Lawrence has the blades of the scarifier never less than $\frac{1}{4}$ in. apart. After thorough "mince-meating" the tissues involving the blood vessels, he uses hot fomentations of Boric Acid, dusts with Iodoform, dresses with Glycogelatin, and applies continuous pressure.

Pressure by an elastic bandage, where the situation of the growth permits gives best results.

Electricity, Iodides, Mercury, Arsenic, Chloride of Gold, and other remedies used with the view of promoting absorption, are useless. Caustics in rare cases have been followed by improvement, but far more frequently by an increase of the growth. The pain and uneasiness which often attend the affection must be met by appropriate remedies. Anodynes like Opium, analgesics like Antipyrine, Cocaine, Exalgin, or large doses of Bromides may be called for.

The sufferer may take some comfort from the fact that the unsightly deformity diminishes or disappears in the course of years.

KERATITIS—See under Cornea (page 173.)

KIDNEY DISEASES—See under Bright's Disease and under Movable Kidney.

KNEE-JOINT DISEASE.

Under Synovitis the main points indicating the treatment of the inflammation of the synovial membrane of the knee will be found. Under Hip-Joint Disease (page 417) and under Joint Disease (page 418) will be found the chief measures applicable to chronic articular ostitis. These may be briefly repeated. They are indicated in all cases of disease involving the cartilages or ends of the bones entering into any articulation in the body. As chronic disease of the knee-joint so frequently has its origin in struma, constitutional remedies are of vital importance. Fresh air, free ventilation, seaside resorts, good food, warm clothing, massage, and every possible measure calculated to improve nutrition and raise the standard of health should be attended to. The drugs to be depended upon in such cases may be mentioned in their order of merit—Cod Liver Oil, Iodide of Iron, Malt Extracts, Hypophosphites, Bichloride of Mercury in very minute doses, Arsenic, and Chloride of Calcium.

Local measures, as already mentioned, will embrace absolute rest by means of splints or extension. Whilst active mischief is present the entire limb should be rendered immovable. Pain may be met by cold or warm applications; counter-irritation by means of blisters or the caustery iron, leeching, or anodyne liniments, or lotions. As the more active symptoms subside, it is of the very greatest moment that the patient should be rescued from the atmosphere of his bedroom and tempted to spend as large a portion of the day as possible in the open air. By means of a Plaster of Paris casing or a leather splint this may be managed without much danger, but the application of a neatly-fitting Thomas's Knee Splint is much better. When it is in use the joint is open to daily inspection or to the convenient application of local remedies, as Iodine Liniment, Lin. Pot. Iod. C. Sapone, Spirit or other lotion. With an accurately fitting splint, and a thick sole on the boot or the sound foot, the patient can walk about without crutches.

Strapping over Mercurial dressing may be applied at a later date, or the pressure of a Martin's Elastic Bandage may be tried.

Abscesses should be opened and thoroughly scraped under an anæsthetic, with rigid aseptic precautions, and if a continuous localised pain over a spot in the head of the tibia, or over either condyle of the femur, should lead the surgeon to suspect a localised abscess in the cancellous tissue, trephining may be seriously contemplated where this is rendered possible without opening into the joint.

When, however, in spite of all these measures, matters go from bad to worse, and the joint becomes hopelessly disorganised, several procedures are available. The most valuable are—

(1) Arthrotomy may be performed—i.e., the joint may be incised, washed out, and drained.

(2) The joint may be incised, and lint saturated in a mixture of strong Sulphuric Acid (1 part) and water (2 parts), may be inserted, after washing out with an antiseptic lotion. By this means, pulpy synovial growths may be dissolved. The method is useless unless where the disease is confined to the synovial lining of the joint, and at the best it is most tedious, and very often ends in failure. Occasionally, however, a firm ankylosis results.

(3) A lateral incision may be made upon each side of the patella, and the pulpy diseased membrane may be scraped away with a Volkmann's spoon. This is seldom successful, as it is impossible to remove more than a comparatively small portion of the diseased tissue, and in the typically strumous joint the removal of every portion of the affected tissues is essential.

(4) These two methods may be combined. After lateral incisions have been made, and as much of the diseased membrane as possible has been removed by Volkmann's spoon, Sulphuric Acid may be freely and repeatedly used with the view of causing destruction of the remainder. Though the joint may be left in a better condition for the subsequent establishment of ankylosis

than if either procedure alone had been employed, nevertheless the same objections remain and another is superadded in the danger of destroying healthy tissue unnecessarily.

(5) The operation of arthrectomy or erosion may be performed. This is really method number 3 systematized and carried out to its very fullest extent. It has been advocated and performed with decided success by Wright and Edmund Owen, who agree in stating that in suitable cases of diseased knee-joint it is better surgery than excision. Owen's paper in the "Transactions of the Medico-Chirurgical Society, Volume lxxi, is a valuable addition to the surgery of the knee-joint. The operation is not applicable to the same extent in the treatment of other large joints. It is based upon the theory of the infective or invading nature of the micro-organisms supposed to be always present in chronic joint disease, and upon whose presence in some small fringe or crevice of the diseased membrane which escapes removal in other operations, failure depends. Its great advantage over excision lies in the fact that it is essentially a conservative operation in that it does not remove any healthy tissue, whilst at the same time, it is an extremely radical one in that it ensures the taking away of all material of a dangerous or suspicious nature. It is, like all measures short of amputation, contra-indicated by the presence of extensive disease of the articular ends of the bone. Ankylosis generally follows, but a good limb may result with moderately free movement—a result midway between that obtained from incision and excision.

The following is Owen's description of the operation—"The operation is commenced by making a bold horse-shoe incision from the tuberosity of one femoral condyle nearly to the tubercle of the tibia and up to the other tuberosity of the femur. The incision opens the joint and divides the ligament of the patella. Bleeding vessels are caught by the self-holding forceps. The crescentic flap with the patella is then turned up and if the subcrural pouch of the articular cavity is not thereon fully exposed, the horns of the incision may be prolonged upwards to the necessary extent. Every ulcerated surface of articular cartilage or bone is then scraped over or scraped out, all pellets and fringes of the synovial membrane are sliced off with curved scissors or scalpel, the semilunar cartilages are taken away, and the crucial ligaments are dissected out. The end of the femur is then thrust out of the wound, and the posterior surface of its condyles, and the synovial recesses above them, and the posterior part of the capsule of the joint are thoroughly scraped. When scraping the front of Winslow's ligament the azygous artery is likely to be wounded and to bleed somewhat vigorously. The subcrural pouch is then thoroughly explored and scraped, the articular surface of the patella is also scraped, and if it be much affected it may be sliced off, but the bone should not be taken away.

"When, to the entire satisfaction of the surgeon and his

assistant, every suspicious area has been efficiently dealt with, the large cavity is thoroughly washed out with a hot solution of Chloride of Zinc or Carbolic Acid.

"If the head of the tibia has been long displaced on to the outer femoral condyle, and the scraping which its inner tuberosity has received does not suffice to allow of the leg being adjusted in a perfectly straight line—and this often happens—the articular surface of the inner femoral condyle must be sliced away until the desired position is attainable. Certainly the bones must not be allowed to become ankylosed with a valgus inclination.

"Provision is then to be made for efficient drainage. Upon this much of the ultimate success of the operation depends; and as the cornua of the wound cannot be depended on for draining the post-condylar recesses, I am in the habit of boring a hole from inside the joint through the ligament of Winslow, using a pair of scissors for the purpose. The position of the popliteal artery having been made out, the index finger of the left hand is lodged in the hollow along the inner side of the biceps tendon, and the skin is traversed at that spot. Occasionally I have drained through the space between the artery and the inner hamstrings. It matters not where the drain is so long as it is efficient. Pus cannot drain uphill. If the tube be passed from the anterior and through the posterior wound, heed must be given that it is not nipped between the femur and tibia when the limb is brought straight. On the whole, it is perhaps better to drain solely by the posterior opening, closing the anterior wound entirely with the exception of its cornua. The limb is then bandaged from the foot upwards, the knee being surrounded by absorbent mercuric wool, and fixed upon the straight back splint, care being taken that the heel does not press upon the pad. The less after this that the limb is disturbed the better. The drainage tube is soon withdrawn, the wearing or starting pains have entirely ceased, and though it must be many months before the limb is serviceable, the disease is probably at an end, and convalescence is established."

(6) Extension of the joint is performed by making a curved incision through the skin, extending from the posterior part of one condyle to the corresponding part of the other. After dissecting up the integument from the front of the patella, the joint is freely opened by a clean sweep through the ligamentum patellæ and lateral ligaments. A thin slice of bone is to be sawn off the lower end of the femur and the upper end of the tibia.

Or the joint may be opened by a free J-shaped incision, and the tubercle of the tibia divided by the osteotome, this preserves the ligament of the patella. The divided tubercle is wired to the shaft before the completion of the operation.

Recently Kocher and others have recommended the removal of a V-shaped piece of bone from the tibia, the femur being sawn so that its cut surface will fit into the V. This is a great advance on the older method, as it prevents backward displacement, and aids

in fixation of the cut surfaces. MacEwen fixes the bones together by long wire nails. The diseased pulpy membrane is to be removed by the knife, scissors, and scraping, the freshly sawn surfaces of bone placed in close apposition, suitable drainage provided, sutures adjusted and the immobility of the limb ensured.

The operation of excision of the knee cannot be said to have met the sanguine expectations of its earlier advocates. To ensure success it must generally speaking, in the opinion of the writer, be undertaken at a stage so early that a natural cure is still possible if the operation be deferred. (See under Hip-joint Disease, page 419.) It is contra-indicated where there is evidence of extensive bone mischief, and in those subjects run down by prolonged exhaustive suppuration, and in most patients past the age of 30 years. The operation of arthrectomy has of late years almost replaced excision in young subjects.

(7) When there is evidence of bone disease extending a considerable way beyond the diseased joint surfaces, where the patient is past middle life or exhausted by prolonged suffering or suppuration, and where the constitutional symptoms clearly show that the system is unequal to the long demand which an arthrectomy, arthrectomy, or excision would entail, and especially where other organs are already showing signs of breaking down, the only legitimate operation will be that of an amputation through the lower third of the femur.

For Koch's method of treating diseased joints arising from tubercular disease, see under Tuberculosis where also is detailed the method of Lannelongue, who injects Chloride of Zinc into the tissues surrounding the tubercular deposits. Under Abscess upon page 15, will be found a brief description of the method of Bruns, who, after aspiration of the joint, injects a sterilised emulsion of Iodoform at various points. Biltroth's operation is a modification of the scraping method just detailed, and of the Iodoform injections of Bruns.

St. Germain's method is described on page 490.

LABOUR.

The management of a case of natural labour need not be here described in detail, the student or practitioner being already quite familiar with the essential points discussed in every text-book on midwifery, regarding the relative duties of nurse and accoucheur, position of the patient, preparation of the bed, instruments to be carried, making examinations, passing the catheter, administering enemata and chloroform, bandaging, &c., &c.

The free use of antiseptics should be emphasized, though the late tendency towards the injection of Mercuric Solution after every examination made during labour is unwarrantable. The attendant should thoroughly cleanse his hands, and after the use of the nail-brush, he should dip them for a few moments into a weak Sublimite Solution (2 grs. in 10 ozs.), or Carbolic Lotion

(1 in 50), and as a lubricant, Carbolized Lard or Oil (1 in 20) may be employed. The golden rule should be that the less interference and manipulation the better for the patient. If any purulent discharge be found present, the vagina should be well douched with a weak Sublimate Solution (1 in 2,000).

When all goes well, the first duty may be to assist nature by pushing upwards the swollen oedematous anterior lip of the os, which may be, in some instances, retarding the descent of the head. If the bladder be full, and its evacuation prevented by the pressure of the head upon the urethra, a catheter should be passed. After full dilatation of the os, the membranes may be ruptured by the finger-nail during a pain if they fail to yield under a few smart pains.

As the head reaches the outlet and presses upon the perineum, this structure must be protected from laceration as far as possible. Unfortunately the means too often employed to prevent this accident may determine rupture. Strong pressure directed against the tense perineum generally aids laceration. In many cases a slight delay gives the tissues time to dilate, and this may be all that is necessary. By strong, direct pressure against the perineum, the uterine pains are increased in force and frequency, gradual natural dilatation is prevented, and laceration is more liable to occur. Hence, some authorities recommend the patient to be encouraged to cease, as far as possible, from making expulsive efforts, in order to give longer time for the natural dilatation or stretching of the part. The left hand laid flat with the palm upon the perineum so as to press the head gently and equably in the direction of the pubic arch, is the best routine method, but it should not be commenced too soon.

The most frequently-practised manoeuvre for the support of the perineum is carried out by placing the left hand against the perineum, whilst the fingers of the right hand are pressed against the head. In this way *extension* of the head and retardation of its descent are at the same time accomplished. Much more power over the head is obtained by pressing against the forehead or orbital margins by means of two fingers inserted into the rectum. Ritgen's manoeuvre is carried out by placing four fingers of the left hand between the tip of the coccyx and anus, while the head is distending the perineum. In this spot the brow and both jaws may be felt, and by pressing, at the end of a pain, the head is prevented from receding, and may be even advanced, whilst the occiput is kept close to the pubic arch, and rotation is assisted.

Dr. Gaussien has drawn attention to another method by which the shortest diameter of the foetal head may be made to pass through the os of the vagina. He aids the movement of *flexion* by traction on the occiput, with two fingers of the right hand inserted behind the symphysis, and as the head is about to clear the os, he renders *flexion* complete by grasping the occiput in the hollow of the right hand, and as he pulls it down from behind the

pubes, the frontal part of the vertex is pushed upwards and backwards towards the sacrum with the thumb of the same hand. The administration of chloroform diminishes the risk of laceration considerably.

Free lubrication of the perineum may be employed in all cases where there is threatening laceration, and where there is much rigidity an incision with the knife or scissors has been recommended, but this is an evil routine practice, and should seldom or never be practised. After labour has been completed, one or two deep sutures should be inserted by means of a curved needle. For sutures to be of use they should be employed at the time. They are unnecessary when the laceration is trivial, and they are useless after a delay of 24 or 48 hours. (See Perineum, Rupture of.)

After the birth of the head, the accoucheur should see that the cord be loosened if it surrounds the neck, and the perineum should be still closely watched during the exit of the shoulders, which may require both traction and rotation.

As soon as the head has cleared the ostium vaginae, and the cord has been removed from the neck if present, the uterus should be firmly grasped by the left hand (see page 363), applied to the surface of the abdomen, and steady, gentle pressure is to be maintained whilst it is felt to diminish in size as the shoulders, trunk, and lower extremities are born.

After a short pause the pressure upon the uterus may be increased in order to hasten the expulsion of the placenta. If this does not show signs of coming away after a short delay, two ligatures may be applied to the umbilical cord, and its section with scissors accomplished midway between the ligatures so as to separate the child from the mother. Most authorities maintain that this separation should not take place until the umbilical vein has collapsed, otherwise a loss of three ounces of blood is suffered by the infant. Spiegelberg consequently advises that the child should not be separated from the mother until after the expulsion of the placenta, or at least not until the latter is beyond reach of the uterine pressure.

By firm pressure applied to the uterus, which should be squeezed and kneaded alternately between the thumb and four fingers of the left hand, the placenta, as a rule, is generally expelled from it without much delay. Markoe lays stress upon the importance of making the axis of the uterine cavity conform to the axis of the vagina in expelling the placenta. When it has been found to enter the vagina moderate traction upon the cord soon brings it within the grasp of the right hand, when it can easily be extracted entire along with the membranes by a rotatory movement. Undue haste and anxiety in the removal of the placenta is to be avoided, as by these means irregular contraction in the uterus may be set up. It is much better that the placenta, where possible, should be expelled entirely by uterine contraction, and it is well

not to apply firm pressure with the view of expelling it for at least a quarter of an hour after the cord has been cut. After its expulsion it should be most carefully examined in order to see that no portion has been left behind.

The invariable custom of the writer was to keep up the uterine contraction for a considerable time after the expulsion of the placenta, in order to guard against hæmorrhage, and with this object he never applied the binder or abdominal bandage till after the infant had been washed and dressed by the nurse. Thus an interval of half an hour was left, during which the uterus could be watched, felt, and kneaded for a few moments, and all clots expelled. If the abdominal bandage and pad be immediately applied after the termination of labour, little can be known about what is going on in the uterus. It is a good rule to give a large dose of Ergot after the removal of the placenta. One full dose of Quinine will act in the same way, and this drug in the opinion of some is much more valuable in simple uterine inertia than is ergot.

Post-partum hæmorrhage is to be met by the remedies mentioned under Hæmorrhage, page 362.

After the expiration of the first 24 hours the nurse should be directed to wash out the vagina with a weak antiseptic solution. Of all the agents of this class Permanganate of Potassium is the most harmless, and, therefore, the one best suited for routine use. Where septic mischief is especially feared, weak Corrosive Sublimate solutions should be employed, but it is better to reserve powerful remedies for special indications, and direct the nurse, as a matter of routine, in every case to inject a pint or more of a mixture of Condy's Fluid and water (a large table-spoonful to one quart of hot water) morning and evening. It is needless to say that this injection or douche should be used when the patient lies upon her left side or back, with a bed-pan slipped under the nates, and precaution should be taken to see that the nurse will not inject the fluid into the uterus; the syphon is better than Higginson's syringe and the nozzle (with its lateral openings) should only be inserted for about two inches into the vagina. The practice of getting out of bed upon the fourth or fifth day, as followed by women of the working classes, is fraught with much danger, and it is a wise rule to confine the lying-in woman to bed for a *minimum* period of eight or nine days. Robust patients may be sometimes permitted to get up after eight days, and weakly patients, in whom the process of involution is tardy, had better be kept in bed for 16 days. Not uncommonly, mischief is done by insisting upon a too-prolonged repose in the horizontal position; but there is more danger to be feared from the patient moving about the room and working with her infant after she is permitted to leave her bed. For ordinary healthy women it is wise to name the beginning of the fourth week as the best time to venture out into the open air.

The bowels require close attention. When there is time a mild purgative or warm water enema should be given at the commencement of labour and no further interference in this direction is called for till the third day, when a mild laxative will help to check any great tension in the breasts. Castor Oil, in doses not exceeding two or three drachms, is the safest of all purgatives at this time. Where there is marked feverishness and constitutional disturbance, with fulness of the breasts, six drachms of Rochelle Salt in half a bottle of aerated lemonade may be given, and repeated in four or six hours if necessary.

The condition of the bladder will require watching, and the catheter may be required from time to time.

The bed clothing should be light, and the lying-in room kept cool and well ventilated, and it should be kept protected from the visitations of sympathetic and officious friends.

The diet for the first two days should be chiefly liquid, any ordinary fever dietary being selected, as weak tea and thin slices of toast, boiled bread and milk, gruel, rennet &c. Upon the third day beef tea, chicken soup, and eggs may be allowed, followed in a day or two by boiled chicken, fish, steaks, chops, or roasts. The over-cautious starvation method often does much harm, especially to suckling women, and from the first, milk may be allowed in small quantities at a time, but as frequently as the patient desires it. Where there are special reasons which hinder the mother from nursing her child the diet should be as free from liquids as possible. Dry biscuits and unbuttered toast may be given, with very small quantities of meat.

As a rule, Alcohol in some form should be always in the lying-in room, but it should be in a sealed bottle, never to be used except in some rare emergency, and then only under the special directions of the medical man. The practice of forcing nursing mothers to drink large quantities of porter, ale, or wine is a serious mistake. For all purposes milk in some form is all that is required, and good buttermilk, when procurable, is the best liquid nourishment after the first week, for nursing mothers.

The treatment of the various complications which may arise during or after labour will be mentioned under their different headings throughout this volume. (See *Hæmorrhage*, *Post-Partum*, page 362. *Pelvicum*, *Rupture of*; *Puerperal Fever*, &c. For *Ophthalmia Neonatorum*, see under *Conjunctivitis*, page 360.)

LARYNGISMUS STRIDULUS.

This true neurosis is not to be confounded with false croup, though it is sometimes called by that name (see page 180). It is also often spoken of as Laryngeal Spasm, Child Crowing, Spasmodic Croup, &c.

Depending, as it does, in some way upon abnormal reflex excitability, and generally associated with rickets, the treatment

will resolve itself, to a great extent, into the treatment detailed under the headings of Rickets, Dentition (Disorders of), Diarrhoea, Convulsions, &c. If seen during the attack which is seldom, as the onset is alarmingly sudden, and its duration exceedingly brief the best thing to do is to dash a little cold water against the face and chest and afterwards plunge the patient into a warm bath. A whiff of Chloroform may be administered. Faradisation of the recurrent laryngeal, tracheotomy or artificial respiration, or the forcible pulling forwards of the tongue, may be resorted to if the physician should happen to be present at an attack which does not yield to a dash of cold water. Ammonia to the nostrils may also be tried.

There is generally no time for the action of an emetic unless in those cases where successions of attacks follow each other. Amyl Nitrite should be worth trial, though the writer has never known of its use in this affection. In the intervals between the attacks, the diet and hygienic surroundings of the infant should be scrupulously attended to (see under Rickets).

Of drugs, a certain amount of success has followed the use of Bromides, Chloral, Musk, Castor, Morphia, Emetics, Nitroglycerin, Succus Conii, and Belladonna. The writer has obtained the best results from full doses of the Bromide of Ammonium of which 2 or 3 grains may be given every three hours, or oftener, to a child one year old. Hensch speaks highly of Morphia, pushed to the extent of causing drowsiness but this treatment cannot be free from serious dangers, especially as the disease rarely, if ever occurs except between the fourth and twenty-fourth month. Lancing of the gums may be tried, but there is little benefit to be expected. Antipyrine in small doses (1 gr. every hour for a child one year old) has been reported as successful in preventing the return of the paroxysms, and Watkins claims excellent results by administering $\frac{1}{2}$ drop of Tincture of Iodine every quarter of an hour at first, and then every one, two, or three hours.

LARYNGITIS.

Acute inflammation of the larynx though to a variable degree an element in croup (see page 180) is for the most part easily distinguishable at the bed-side.

Fagge separates croup from acute laryngitis by the broad distinction that in croup there is the dangerous dyspnoea, whilst in acute, or acute catarrhal laryngitis the prevailing symptom is impairment of the voice.

The treatment is to be carried out upon the same principles as those fully detailed under Croup.

The patient should be directed to give his larynx as much rest as possible, speaking being forbidden. He should be placed in bed in a warm room (65° F.) the air of which should be moistened with the vapour of water. This may be accomplished by the use

of the bronchitis kettle or by any of the various steam inhalers. The vapour of the Compound Tincture of Benzoin may be used with advantage, the old B.P. inhalation of Conium, or the diluted vapour of a small quantity of weak Tincture of Iodine or Carbolic Acid.

Poultices, or warm fomentations, or Spongio-Piline wrung out of hot water, should be applied to the larynx—the latter is the most convenient and soothing. Cold may be tried where warmth is found to aggravate. Warm demulcent drinks should be freely administered and perspiration encouraged. The following mixture for an adult is suitable, and where the symptoms are urgent an emetic ($\frac{1}{8}$ gr. Apomorphine hypodermically) may be first administered:—

R. *Liquor. Ammon. Acetatis* ℥ii.
 Vin. Antimonialis ℥vj.
 Liquor. Morphine Hydroch. ℥ii.
 Succi Conii ℥j.
 Aqua Camphoræ ad ℥x. *misce.*

Fiat mistura. Capiat cochlearium magnum quartis horis.

Tracheotomy, or scarification of the glottis, may be called for, and the after-treatment will be similar to that described under Croup.

As the more urgent inflammatory symptoms are overcome, if pain persists it is best relieved by the following solution, which can be freely used as a spray every three or four hours or oftener:—

R. *Cocaine Hydrochloratis* gr. x.
 Glycerini Acidi Carbolici ℥iv.
 Aqua Rosæ ad ℥x. *misce.*

Fiat solutio *Signa*—"To be used occasionally as a gargle, and frequently as a spray."

Williams recommends spraying of the throat with an oil atomiser charged with a 5 per cent. solution of Menthhol in Paroleine, and if there be any delay in the disappearance of the symptoms he paints the larynx with a solution of 20-30 grs. Chloride of Zinc to 1 oz. water.

Freezing the skin over the thyroid space where the internal laryngeal nerve enters is said by Abrams to be both curative and anodyne.

As the symptoms pass off a weak gargle of Tannic Acid, 1 drachm in 8 ozs. Acid Infusion of Roses, may be used with advantage.

The treatment of chronic laryngitis as a cause of hoarseness has

already been briefly referred to (page 421). The management of such cases is often most tedious and unsatisfactory. Rest of the vocal organs for a time is essential, and though every constitutional disturbance or error is to be corrected by improved hygienic surroundings, including change of residence for a time to a bracing or mild atmosphere, nevertheless the most striking results are always to be obtained by local remedies.

Nitrate of Silver, used either in solution (30 to 60 grs. to 1 oz. water) or as the mitigated or solid stick, should be applied to the interior of the larynx every 2 or 3 days. The latter is a very severe and painful remedy. Often a weak solution (20 grs. to 1 oz.) brushed daily over the interior of the larynx gives better results than the stronger solutions which can only be used at considerable intervals. Chloride of Zinc (3 grs. to 1 drachm) is the best remedy when a purely astringent effect is desired. Where the cords are thickened a 40 per cent. Lactic Acid Solution may be used.

These strong local applications can only be made by the physician—a serious drawback in the treatment and management of a chronic disorder—and hence the great value of sprays and inhalations, which can be used by the patient as often as deemed desirable. Of the astringent spray solutions the following are the best:—Alum (5 grs. to 1 oz.), Tannic Acid (5 grs. to 1 oz.), Perchloride of Iron (5–10 minims of the weak liquor to 1 oz.), Sulphate of Zinc (2 grs. to 1 oz.), Sulphate of Copper (1 gr. to 2 ozs.) and when an alterative effect is desired Tincture of Iodine (5 minims to 1 oz.), Chloride of Ammonium (10 grs. to 1 oz.).

Bromide of Ammonium (5 grs. to 1 oz.), Eucalyptus Oil (2 minims to 1 oz.), Fir-wood Oil (2 minims to 1 oz.), Perchloride of Mercury ($\frac{1}{2}$ grain to 1 oz.), Speecacuanha Wine (100 minims to 1 oz.), Sulphurous Acid ($\frac{1}{2}$ drachm to 1 oz.), may be employed.

Where dysphagia, pain, and irritable cough are distressing, the spray which the writer has found most useful is that formulated upon the previous page, containing Cocaine and Carbolic Acid, but it should only be used for short periods, as Cocaine tends to keep up the disorder if persisted in. Menthol, 5 per cent. in paroline, is much better.

Inhalations are useful when a soothing effect is desired, though other actions may be obtained by using various volatile substances in this form. Commum inhalation hot water containing Eucalyptus, Terebene, Fir-wood Oil, Creosote, Menthol, Carbolic Acid, Iodine, Benzoin or Friar's Balsam, may be each advantageously used as an inhalation.

Good results may be obtained from the Chloride of Ammonium Inhaler. Pinus Pumilio Oil 15 minims to 1 pint water at 160° F. is a grateful inhalation. Insufflations employed by blowing finely pulverised substances, such as mixtures of powdered Starch, Bismuth, and Morphia, are seldom followed by much relief.

The constant current, Faradisation, or static electricity may be tried with benefit in some cases of chronic laryngitis.

Rheumatic laryngitis is a very chronic and troublesome affection. Ingals has found benefit follow its treatment by the astringent and soothing sprays and inhalations mentioned above, but he relies mainly upon constitutional remedies directed to the diathesis, as Iodide of Potassium, Salicylates, Colchicum, Cimicifuga, and Guaiacum.

Tubercular laryngitis.—The treatment of tubercular disease of the larynx, as of any other region, will be feeble and unavailing if not directed chiefly against the hereditary or acquired condition which permits the growth and development of the micro-organism. Consequently the various agents useful in the treatment of Scrofula and Phthisis (especially saturation of the blood by Creosote administration), and every possible means whereby nutrition may be improved, must be scrupulously attended to before local remedies are seriously decided upon.

Local treatment may be mentioned under two heads—viz., (1) remedies used to relieve pain, dysphagia, and cough, and (2) measures directed to the removal of the local deposits or injured tissue.

Rest to the larynx should, as far as possible, be insisted upon, as the use of the voice prevents or retards the reparative process. Hot or cold currents of air, very hot or very cold foods, are to be also avoided, as well as tobacco smoking and the inhalation of irritating dust, &c., and the use of much alcohol. A warm, moist climate is much better than a dry, bracing atmosphere.

Cough should be quieted, as far as this can with safety be accomplished, by anodynes internally, and by soothing inhalations or sprays.

There are diverse opinions held regarding the value of Cocaine in laryngeal suffering. The writer has satisfied himself of the very great comforts which its use affords for a brief period, in many cases beyond the reach of relief in any other way. It may be used as the spray previously mentioned or a 10 per. cent. solution may be brushed freely over the interior of the larynx. Glycerin of Borax is a good vehicle for the drug.

R *Cocaina Hydrochloratis* ℥ss.
 Aqua Destillata ℥ss.
 Glycerini Boracis ad ʒi. *misce*

Fiat solutio M d. u.

Cocaine is also employed in the form of an insufflation and in pastilles. After the use of cocaine sometimes the patient can take food with comfort when swallowing had been previously distressing or impossible, especially where there has been much ulceration or perichondritis present, and in the later stages of the disease its use will enable the physician to prolong life.

Insufflations of Iodol, or Iodoform, mixed with half a grain of

finely-powdered Morphine, have been used to relieve pain and dysphagia. The powder should be blown upon the ulcerated spots, the laryngeal mirror being always used. Bismuth and Boracic Acid may be also employed with Morphine instead of Iodoform, and the ulcerated spots should first be well cleared of mucus before insufflation.

Orthoform as a 25 per cent. emulsion with olive oil or egg yolk is a valuable analgesic; it may also be used as an insufflation mixed with an equal amount of Iodoform.

Neumann, who treats the early catarrhal stage by a solution of Sulphate of Zinc mixed with a 1 or 2 per cent. solution of Cocaine, speaks in very high terms of the valuable and surprising anodyne effects of large insufflations of Iodoform in those cases characterised by extensive tubercular ulcerations. He also uses in less severe cases an insufflation of equal parts of Boric Acid and Iodol, and in the later or final stages of the disease he finds a 5-15 per cent. cocaine solution of the greatest use in enabling the patient to swallow. He reports highly of Lactic Acid and Tracheotomy, and thinks menthol inferior to cocaine.

Menthol is unquestionably, upon the authority of many specialists, of great value in the treatment of laryngeal tuberculosis. It relieves pain, acting as a local anaesthetic, and it is claimed for it that it destroys the local deposits of the disease. It may be taken internally at the same time, applied with a brush, or used as an inhalation, or injected.

The most satisfactory application for the local use of Menthol is a solution of 1 part in 10 parts of pure Olive Oil. This may be brushed freely over the affected parts daily for long periods, but it is always better to employ a 20 per cent. (1 in 5) solution after the first week. It is not caustic, and its analgesic properties do not become diminished by repeated applications.

A 30 per cent. solution has been used, but it causes considerable pain, and is apparently not followed by better results than those observed after the weaker solutions. The effects of the menthol can be kept up by the patient wearing a small Coghill's respirator for the greater portion of the day, with the sponge moistened with a mixture of Creosote and Menthol or other volatile antiseptics.

The following formula is useful for this purpose :—

R.	Acid. Carbolic.	ʒij.
	Creosoti Purif.	ʒj.
	Spt. Chloroformi	ʒij
	Thymol	gr xxx
	Aquæ Destill.	ʒxv.
	Spirit Vini Rect ad	ʒiv. misce.

Fiat solutio secundum artem.

The following may be insufflated—1 dr. Iodoform, 8 grs. Menthol, 1 dr. Boric Acid, and Phosphate of Lime, 1 oz.

Of measures directed to the destruction of the diseased or ulcerated spots there have been many reports from various quarters of successes and "cures" after the use of Lactic Acid. This is used in various ways, the simplest being to brush over the affected surface of the larynx with a 30 per cent solution, gradually increased to a 75 per cent solution. Some surgeons prefer to inject a few drops into the interior of the larynx with a laryngeal syringe. The pain and irritation following the application is much diminished by a previous swabbing with cocaine.

Allowing for the enthusiasm of the advocates of this method of treating tubercular laryngitis, there cannot be a doubt but excellent and lasting good results have been obtained. Some surgeons have injected the acid under the diseased mucous membrane, as others have injected Iodoform, in the same manner and with the same intention. The writer has had no experience of the local application of this acid to the larynx, but he has repeatedly satisfied himself about its striking action when applied to tubercular lupus on the face. It destroys the diseased tissue, and appears to have no injurious effect whatever upon the healthy structures in the immediate vicinity.

Not content with the action of 80 per cent. solution of Lactic Acid, Ehring has gone a step further and scraped the ulcerated spots in the larynx till he removed all the diseased tissue, after which he applies the acid or injects it under the membrane. This he has done in 200 cases, with the report of 28 cures. Keimer follows much the same practice. He rubs the acid in with a brush after curetting, and Semon after scraping the base of the ulcers by Heryng's curette rubs in the acid (20-80 per cent.) Formic Aldehyde and Sulpho-Ricinoleate of Phenol are also locally applied in ulceration with oedema.

Kohlscher injects the acid solution of Phosphate of Lime, which has been found to cause the absorption of tubercular or caseous masses in diseased joints. Prosser James, however, justly expresses a note of warning, and points out the dangers of these heroic interstitial laryngeal injections, and it would seem judicious at present to limit their use to the hands of experienced specialists. The same remark might be also applied to the deep scarifications recommended and carried out by Schmidt, and to the use of the galvanocautery.

Where deep and extensive ulcerations exist, beyond the reach of these remedies, there may be nothing left to save the patient from a painful death but tracheotomy.

Garel advises submucous injections of cocaine followed by the galvanocautery and Lactic Acid, and condemns tuberculin and cantharidinates of soda.

Where the difficulty of swallowing is great, and does not yield to cocaine, it may be necessary to feed the patient through a soft

rubber oesophageal tube. Thick liquids are more easily swallowed than thin ones, and in some cases Wolfenden's plan of getting the patient to lie upon a couch or bed with his head hanging down over the side while he swallows may be successful.

Syphilitic laryngitis.—The treatment should consist of vigorous constitutional remedies, suitable to the stage in which the syphilitic affection is existing at the time. In the later part of the secondary stage of syphilis, rapid mercurialisation should be carried out byunction of Mercurial Ointment. Laryngeal mischief occurring during the tertiary stage of the disease is best met by heroic doses of Iodide of Potassium—20 grs. three times a day, after meals, may be given. Where the case does not respond to the iodide, and the symptoms increase in gravity, a course of mercurialunction should be at once commenced. The local symptoms can be best met by the various anodyne and astringent sprays and inhalations previously mentioned. A weak solution of Corrosive Sublimate ($\frac{1}{4}$ grain to 1 oz.) is the best spray to use in such cases.

Inhalations of Iodoform are of the greatest use in many cases where much ulceration exists, and in the late stages of the disease Cocaine may enable the starving patient to swallow with ease and safety.

The solid Nitrate of Silver may be freely applied to ulcerations, or a solution of Corrosive Sublimate (5 grs. to 1 oz.) may be used, with the aid of the laryngeal mirror. Sulphate of Copper (15 to 20 grs. to 1 oz.) is a favourite local remedy.

Where there is much oedema, free scarifications may be needed, and sometimes intubation or tracheotomy may be demanded. After-treatment may be necessary for the removal of warty growths, cicatricial bands or webs, or narrowing.

LEAD POISONING—See Colic, Plumbism, and Poisoning.

LENTIGO OR FRECKLES—See Chloasma.

LEPROSY.

Notwithstanding the labour expended upon the pathology of this terrible malady, it must be still included in the list of incurable diseases. By absolute isolation of the leprosy from healthy individuals, and by the isolation of individual lepers, there is no doubt that the disease can be stamped out ultimately in districts ravaged by its presence. By the judicious and persistent use of certain remedial agents the disease may be retarded, and suffering may to a very considerable extent be alleviated. Good food, moderate exercise, free ventilation, and as much pure open air as the patient's surroundings will permit, may be indulged in to advantage. Agents which improve nutrition, as tonics and Cod Liver Oil, are always useful. Iron, Arsenic, Iodine, Phosphorus, Salicylates, Salol, Iodides, Hoang Nan, Tuberculin, Chlorate of Potassium, Thyroid Gland, Mercury in minute doses, and a long

list of vegetable substances, about whose physiological action nothing whatever is known, have been tried in vain. Of these latter empiric agents there are two which have met with results which warrant their recommendation as valuable palliatives. Some affirm that in mild cases they are curative, but the cases of leprosy which have been reported as cured by their use are not believed by some authorities to have been true examples of the disease. These agents are Gurjun Balsam or Oil, and Chaulmoogra Oil or its active principle—Gynocardic Acid. Both remedies are applied externally and taken internally at the same time. Both are as repulsive as copaiba, and as liable to upset the stomach.

Gynocardic Acid in doses of 1 grain may be given in the form of pills after each meal, and the Chaulmoogra Oil may be administered in the form of capsules (5 minims in each) two three times a day, or as an emulsion or mixed with fresh cream. The dose should be gradually increased till the patient can bear no further addition, after which the maximum amount may be persisted in as long as the patient remains able to swallow it without suffering diarrhoea or vomiting. T. Bey has given the oil by the hypodermic method with marked success without producing local disturbance.

Externally, the oil should be freely and forcibly rubbed into the affected regions after being diluted with twice as much pure lard, or with an equal amount of lime water in an emulsion. The friction should be repeated several times a day for 15 or 30 minutes each time, and a cloth or dressing saturated with the ointment should be left in contact with the diseased surfaces. From the beginning of the treatment the skin should never be permitted to get free from this greasy application, except for the short time during which the patient is getting cleansed from time to time by hot baths, after which the frictions are to be immediately resumed.

Gurjun Oil, or Dipterocarpus Balsam as it is also called, is likewise used both externally and internally, and most Indian physicians prefer it to the Chaulmoogra Oil. It may be given in the form of an emulsion in doses of 5 to 15 minims, or in the form of capsules. In India a table-spoonful of an emulsion made by shaking up 2 ozs. of the oil with 6 ozs. Lime Water is given twice a day, but the more civilised stomachs will not bear half this amount.

Radcliffe Crocker combines intra-muscular injections of Perchloride of Mercury with the internal use of Chaulmoogra Oil.

Serumtherapy has been tried by Carrasquilla, who injects the serum of the horse and ass after these animals have been treated by injections of the serum from human lepers. The reports are contradictory. Merck's Serum is also on trial.

For external application a liniment made by shaking up equal

parts of the oil lime water, and lard oil, should be rubbed in very often with moderate pressure.

Some cures are reported from these agents and from the Bombay treatment by Cowli Oil. Cashew-nut Oil has its advocates, it acts as a caustic when applied to the nodules and patches.

Ulcerations are to be treated upon general surgical principles. Unna's Ichthyol or Resorein Ointments (25 per cent.) are good dressings to use after applying concentrated Carbohc Acid where the ulcerated surface is limited. Iodoform gauze may be employed in some cases, but Oakum teased out carefully may make a cheap and very valuable dressing superior to all others where expense is an important object.

Müller applies Chinisol, and gives it internally in doses of 15 grs.

Unna uses a 10 per cent. Pyrogallie Acid Ointment to the limbs, and a 10 per cent. Chrysarobin Ointment to the rest of the body, and in severe cases recommends that the tubercles be excised and Ichthyol given internally for long periods.

Other antiseptics, as Creosote and Carbohc Acid (1 in 10), Salicylic Acid, Boracic Acid, Iodoform, Creolin, Corrosive Sublimate, Mercurial Ointment, &c., have been used, but with very varying successes. Cocaine and Morphine may be used to relieve pain and hyperæsthesia, and Crocker reports that stretching of the affected nerve in non-tubercular leprosy has been of much use in relieving paralysis and anæsthesia.

LEUCODERMA or VITILIGO.

The white, rounded or circular patches in this disfiguring affection of the skin are practically beyond the reach of treatment. These patches are always surrounded by a zone of skin containing an abnormal amount of pigment, and as most of the deformity may be owing to the marked contrast between the two colorations, much may be done by removal of the increased pigmentation to render the appearance of the patient less remarkable. Weak Solutions of Corrosive Sublimate (1 to 3 grs. to 1 oz.) may be often used with much advantage for this purpose when the spots attack the face or upper portion of the neck. The writer has been able in one case to very materially improve the appearance of a female patient to whom the presence of this affection was a serious distress. Peroxide of Hydrogen has been also successfully used to destroy or lessen the pigmentation. Repeated applications of small circular blisters of the Cantharides Plaster of the B.P., which may be left in contact with the whitened patch for one or two hours at a time, may sometimes induce a slight amount of pigmentation. The blister should be a little smaller than the unpigmented area, sometimes Cantharides increases the pigmentation. Internal remedies are useless, and galvanism is of little or no value.

Blistering can be more successfully carried out by laying a piece of lint soaked in a solution of Corrosive Sublimate (5 grs. to 1 oz.), and covering it over with oiled silk, for three to five hours, and dressing afterwards with Bone Acid powder.

Salicylic Acid in saturated alcoholic solution, or in the form of plaster or paste, is decidedly preferable to Cantharides, and Resorcin paste (1 to 15) sometimes acts well.

The writer has recently had good results by repeatedly staining the skin deeply by strong solution of Permanganate of Potassium, and then washing with saturated solution of Oxalic Acid.

LEUCOCYTHÆMIA or SPLENIC LEUKÆMIA.

In the early stages of this disease the reports of trustworthy authorities prove that permanent recovery sometimes follows the use of certain remedies, though there must always be some doubt about the diagnosis in these cases. These remedies are by common consent, however, held to be useless in advanced stages of the disease, and it comes consequently to be a question if they deserve any credit in removing the splenic enlargement and altering the condition of the blood when given in the earlier stages. It must remain at present an open question whether the so-called cures have any relation to the remedies employed. They might have resolved had no drug been employed at all. Until the natural history and progress of the affection have been thoroughly worked out by collecting cases in which no drugs have been employed we are likely to remain in some doubt. Nevertheless, in the face of statements made upon the best authority, it must at present be considered our duty to give accredited remedies the fullest trial. Where any history of ague has been made out, the lines of treatment are very clear.

Improved hygienic surroundings and attention to every error in living is of obvious importance, and where the patient resides in a malarious district, his removal to a healthy sea-side resort should be early insisted upon when the season permits.

It is of importance to restrict the exercise of the patient to that of moderate activity, as violent movements of the body are not safe when a large vascular tumour like the spleen is suspended in the abdominal cavity. Chills and sudden variations of temperature are to be guarded against by warm clothing and avoidance of wettings. The pregnant condition, which is not a very rare complication of leukæmia, requires special care, and the lying-in period is not free from hæmorrhagic dangers and anxieties.

Of drugs the reports are conflicting. Muir maintains that Arsenic is the only agent which affords any hope. Most authorities agree with him that it often prolongs life, and a few sanguine observers believe that they have seen cures from its use, but it must be said that the great bulk of cases relapse from the temporary benefits produced by the administration of the drug. In our present state of helplessness it seems to be the duty of the

physician to press this remedy in steadily-increasing doses. It may be given in doses of 10-15 minims of Fowler's Solution three times a day by the mouth, or injected hypodermically, well diluted with water, and without the red lavender, which adds to the local irritation: or it may be given by the rectum. The Cacodylate of Soda, which is now being extensively lauded by French physicians, may prove more satisfactory. (See under *Anæmia, Pernicious*, page 45.) The writer has seen recently striking improvement follow its administration in both the splenic and lymphatic forms of the disease, and the cases are still under observation.

Where any history of malaria or residence in a malarious region is obtainable, hope lies in large doses of Quinine, though this drug seems to be valueless in the pure lymphatic form of the disease. It must be given in large and repeated doses, such quantities being administered every eight hours as will keep the patient constantly upon the verge of cinchonism. Often under its use the enlarged spleen will be found to diminish in size, and gradual improvement set in in all the symptoms.

When Quinine fails to reduce the dimensions of the enlarged organ after a considerable trial, the following drugs in their order may be administered with some hope of success.—Phosphorus, $\frac{1}{16}$ grain, in pill, three times a day; Iron, in 30 to 45 minim doses of the dialysed liquid preparation after each meal. Iodide of Potassium, 10 grains, in two pills, given in conjunction with Cod Liver Oil, or alone. Eucalyptus and Piperine have been advocated, and some observers report improvement from the administration of Bone Marrow, but the value of these agents is very doubtful. Thymus and Thyroid feeding, and the use of Spleen Pulp and Calcium Salts, have led to no useful purpose. The best results observed by the writer in the spleno-medullary form were obtained by large doses of Quinine (10 grs.) with 10 minims of Fowler's Solution three times a day and he believes that he has been able to prolong life by this combination.

Electricity has a powerful influence over the spleen, and in conjunction with any of the above remedies, or alone, a strong, continuous current should be sent through the enlarged organ, one pole being placed on the ribs behind, and the other upon the abdominal parietes over the centre of the tumour in front. The electrodes should be large and well covered with layers of leather, and moistened with warm saline solution, and the current from 20 Leclanché cells may be employed twice a day, for 15 minutes each time reversing and moving the electrodes about. Where no striking effects follow, Faradisation may be resorted to.

The practice of injecting Ergotin into the tumour has not been followed by success sufficient to warrant its routine employment. A jet of cold water, directed with moderate force against the left side of the abdomen whilst the patient stands or lies partially immersed in a warm bath, has occasionally been followed by a diminution of the tumour and amelioration of the symptoms.

Inhalations of Oxygen have been reported as successful, but this has been denied by many observers, and some have administered Carbon Dioxide in conjunction with it. The application of counter-irritants is of little value in reducing the size of the enlarged spleen, though pain may be relieved in this way. The ointment of the Red Iodide of Mercury has been employed, but its value is very doubtful. The writer has observed some benefit from wearing a large piece of Spongio-piline smeared over with the liniment of Iodide of Potassium and Soap, and kept in its place by the pressure of a firm abdominal binder. It is not easy to determine whether the benefit is owing to the iodide or to the pressure in this case, or to the friction sometimes employed in rubbing in the liniment.

In the advanced state of the disease all measures are worthless, and excision of the diseased organ has been almost invariably fatal, and Muir regards the operation as absolutely unjustifiable. Some temporary delay has probably occurred to the advance of the fatal issue by transfusion, but occasionally it has appeared to hasten the end.

The various complications which arise, such as syncope, hæmorrhage, peritonitis, pleuritis with effusion, dyspnoea, anasarca, &c., are to be treated upon the general principles detailed under the head of each.

LEUCORRHEEA.

As this is but a *symptom* or sign of many different affections, a routine treatment is to be avoided. The first thing to do is to determine the cause of the discharge. It may arise from uterine displacements, endometritis, salpingitis, polypi, disease of the cervix, vaginitis, or vulvo-vaginitis. The treatment of most of these affections will be found under their appropriate headings.

If we regard leucorrhœa as the result of a catarrhal condition of the lining membrane of the uterus, of the cervical canal, or of the vagina, a rational basis will be at once evident for the treatment of the great bulk of cases coming under the physician's notice, and it is certain that this catarrhal condition is very often but the local manifestation of a general condition, as *anæmia*, *chlorosis*, *gout*, *gastric derangements*, *obstinate constipation*, *circulatory lesions*, &c. It is this constitutional condition which calls for immediate relief, and in many instances local or surgical procedures do harm. Thus the discharge often appears in weak, over-worked young women living in ill-ventilated rooms and on improper food, which reduces their vital energy, producing *anæmia* and *dyspepsia*.

The leucorrhœa disappears with the proper improvement in their environment. Iron is the drug which gives best results in all *anæmic* cases, and in the leucorrhœa of virgins all vaginal examinations should be avoided, and a course of this drug be

commenced, unless where other symptoms point to some definite mischief beyond catarrhal endometritis. Two Hlaud's Pills three times a day, or the following pill — *B. Ferni Redact.*, gr. ii.; *Ferni Arseniatis*, gr. $\frac{1}{2}$; *Quinæ Sulph.*, gr. i.; *Ext. Nuc. Vom.*, gr. $\frac{1}{4}$; one thrice daily after food, or the elegant effervescent mixture containing a scale preparation mentioned on page 43, may be tried.

At a later stage tonics, containing Quinine and a diluted Mineral Acid, may be substituted. Good food, pure air, cold bathing, moderate exercise, warm clothing, especial attention being directed to the covering of the feet and legs, early hours and a change of scene when convenient, are to be recommended.

Local remedies may be used in obstinate cases, but the patient should be carefully instructed about their use either by the physician or through a nurse. Of the various forms of douche apparatus the best is the simple rubber Higginson's syringe, or the rubber syphon apparatus. A soft vaginal pipe, with the end perforated by several lateral apertures, should be used.

The various astringent solutions should be injected warm at first, but as the patient becomes familiar with their use the temperature may be gradually lessened until, in summer liquids of the same temperature as the surrounding atmosphere may be used.

The sitting posture is the most convenient, and the injection or douche may often with advantage be administered when the patient is in a warm or sitz bath. Two points, frequently overlooked in the use of astringent douches, are of much importance—at least one quart or 40 ozs. of the solution should be used at each time, and the vagina should be first thoroughly flushed out by a stream of warm or tepid water before the introduction of the astringent. When this latter precaution is not taken, the injection of the remedy may cause coagulation of any secretions in the vagina and lower parts of the cervical canal, and the coagulated or thickened secretion adheres tenaciously to the diseased membrane, and prevents the action of the solution, or it may even, by its presence, become a further source of irritation.

Moreover, a stream of hot water has been found by itself to be a powerful alterative to the diseased mucous surface of the vagina, and is a favourite remedy with some physicians who only employ astringents after they have found it to fail in reducing the amount of the discharge. It is found to act best where there is marked congestion of the vaginal or uterine walls.

In married patients, when examination reveals an inflamed cervical canal or eroded os, the application of a strong caustic, brought into contact with the secreting membrane by a piece of cotton wool on a Playfair's probe through the speculum, is the first step in the treatment. Iodized Phenol prepared after the following formula, is the best agent for this purpose:—

R. *Iodi Purificati* ʒj.
 Acidi Carbolici ʒiv. *misce.*

Fiat solutio cum calore.

By displacing 2 oz. of the Carbolic Acid in the above with 1 oz. Chloral Goodell's application can be made.

After a few applications of the above, any of the astringent lotions to be presently mentioned may be used till the discharge disappears. The writer has generally found that few cases of this kind resist one or two such applications, if the vagina be partially filled through the speculum with about an ounce of finely-powdered Boracic Acid, kept in position for 24 or 48 hours by a plug of absorbent cotton wool soaked in the B.P. Glycerin of Borax.

Constitutional treatment with Iron, Tonics, sea bathing, and change of air and scene and the correction of any dyspepsia, constipation, or other departure from health, will greatly facilitate the disappearance of the discharge.

Pure Carbolic or strong Nitric Acid, solid Nitrate of Silver, strong Perchloride of Iron or Acid Nitrate of Mercury Solution, may be applied to the interior of the cervical canal instead of the Iodized Phenol.

When leucorrhœa is simply the discharge coming from diseased and dilated tubes which finds its way into the vagina through the uterus, this treatment may aggravate matters by causing retention of the secretion. (See under Endometritis.)

Where the ordinary astringent injections and plugging with Boracic Acid fail, it is recommended to paint the interior of the vagina over with a strong solution of Nitrate of Silver or other caustic. This should seldom be resorted to, though where there is a granular vaginitis with much excoriation or a vulvo-vaginitis, with intense itching, the 30 grs. to 1 oz. solution freely applied often gives speedy and lasting relief. Ointment of Contum with Ichthyol is an invaluable sedative in such cases. Where the discharge is profuse the external surface should be well protected from the irritating secretion by being smeared over with some greasy preparation (see Eczema), and the vaginal douche should be used three or four times a day; in ordinary cases twice daily will suffice.

Remedies in the form of medicated pessaries are, as a rule, objectionable. As the mass melts it mixes with the discharge, and makes a disagreeable mess, which adds much to the patient's discomfort.

Belladonna, Creosote, Carbolic Acid, Tannin, Iodoform, Bismuth &c., are used in this form.

The following are the usual astringent injections enumerated in the order in which the writer has found them in his experience to

be best suited for ordinary vaginal leucorrhœa. The quantities are given for one quart of tepid water —

Powdered Alum, 1 oz ; Powdered Borax, 1 oz ; Boracic Acid, 1 oz. ; Sulphate of Zinc, 2 drachms ; Iron Alum, 2 drachms ; Tincture of Iron, 2 drachms ; Sulphate of Copper, 30 grains ; Tincture of Iodine, 30 minims ; Carbolic Acid, 2 drachms ; Acetate of Lead, 30 grains ; Tannic Acid, 1 drachm ; Corrosive Sublimate, 5 grs. (this powerful agent is not suitable for constant daily use) ; Bicarbonate of Soda or Potash, 2 drs. ; Permanganate of Potash, 10 grs. ; Chloral Hydrate, 40 grs ; Nitrate of Silver 20 grs.

Lime water, injected in its strength, or mixed with as much water, is an old favourite.

Infantile leucorrhœa is most generally of vulvar origin, and may be often treated as a simple intertrigo by absolute cleanliness and a lotion composed of any of the above solutions.

LICHEN.

The lichen group of skin diseases is still in confusion, some authorities describing the different varieties of the affection by names which are applied to totally different diseases by other writers. Some of the diseases grouped together as lichen have nothing in common with each other. Lichen ruber or planus is best treated by Arsenic internally. It is often most tedious in its response to remedies, but the steady and persistent use of arsenic will almost always reward the physician in the end. The fullest doses should be persisted in for long periods, beginning with 3 minims of Fowler's Solution. This amount may be cautiously increased till 8 or 12 minims are given three times a day. After reported failure, success is said to have been achieved by the hypodermic administration of the drug, freely diluted with water. Kaposi and Hebra give the arsenic in adult cases always in the form of Asiatic Pills ($\frac{1}{4}$ gr in each), and they increase the dose till 8 or 10 pills are taken as the daily amount, this dose being reached in about 4 weeks, and it is continued till the affection begins to disappear, but the writer has never ventured upon such heroic dosage. With the arsenic may for a time be combined Iron, Cod Liver Oil, and every remedy or food which improves nutrition and raises the standard of health. Sleep is of much importance, over-work and worry, with irregular hours, having more aggravating influence than is generally recognised.

Where arsenic cannot be tolerated, or where it fails to make a decided impression upon the disease, the recognised plan of procedure is to resort to a mild Mercurial course, and this is best in all acute cases before arsenic is admissible. The Biniodide of Mercury, in the form of minute pilules, each containing $\frac{1}{4}$ grain, may be given after each meal. The perchloride is most often used $\frac{1}{4}$ grain in solution three times a day. Many other remedies have been advised, but if arsenic and mercury fail, except Phos-

phorus, no other drugs appear to have any specific action. In acute cases Brooke gives small doses of Tartarized Antimony. Brocq's treatment consists in the administration of Quinine combined with Ergot and Belladonna.

Locally the treatment best suited to lichen planus is that which gives good results in psoriasis—i.e., a stimulating Tar ointment. The *Liquor Carbonis Detergens* and the Oil of Cade (1 drachm to 1 oz. Lard) are good substitutes for the ordinary tar ointment.

The treatment must, however, largely depend upon the presence or absence of itching. When this is a marked feature, the management of the case is difficult. If the papules are confined to a small surface of the body, a solution of 1 oz. of Bicarbonate of Sodium dissolved in 30 oz. of water is a good sedative lotion. Where large tracts of the skin are involved, hot Alkaline baths, frequently administered, are indicated. A lotion consisting of 1 oz. of the *Liquor Carbonis Detergens*, 1 oz. strong solution of Acetate of Lead, in 40 oz. Distilled Water, may be tried. Unna's ointment is often very useful—he has successfully treated many cases by frictions twice daily with it and no internal medication whatever.

R. *Hydrarg. Perchloridi* gr. viii.
 Acid. Carbolicæ ℥j
 Ungt. Zinci ℥ij. *misce.*

In obstinate cases where he has to deal with small thickened patches the amount of sublimate is increased to 60 grs.

Carbolic Acid or Creosote, in the form of ointment (1 in 20), or as a lotion (1 in 50), may be used. Nitrate of Silver, 20 grs. to 1 oz. of Spt. *Ætheris Nitrosi*, may be painted over the itching surface when the above remedies fail.

Old-standing patches may be treated by *Emplastrum Hydrargyri* or Salicylic Acid, or a 5 to 10 per cent Pyrogallie Ointment, or by Chrysarobin, or, as advocated by some dermatologists, by the actual cautery.

Jacquet's method, based upon the neurotic theory of lichen, has given excellent results. He projects a warm douche (33° to 38° C.), with some force against the back on each side of the vertebral column, for about 5 minutes once or twice daily, followed by a dash of cold water. This plan has been used successfully in prurigo, eczema, and various trophic skin affections.

For *Lichen Scrofulosorum* the remedies suitable for scrofula are indicated—i.e., Cod Liver Oil with Syrup of Iodide of Iron and at a later stage small doses of Arsenic in combination with Iron.

Lichen Pilans yields to weak Alkaline baths and friction, followed by theunction of any bland oil like *Oleum Olivæ* or Cod Liver Oil.

LIGHTNING INJURIES AND ACCIDENTS.

Unfortunately becoming common since the introduction of the electric current as a means of illumination and a source of mechanical power, are to be treated upon general principles. The shock or collapse is to be met by the remedies already mentioned upon page 156. Thus warmth and friction to the surface of the body with the hypodermic or rectal administration of diffusible stimulants such as Alcohol, Ether, or Ammonia, the Cold and Hot Douche alternately, with Artificial Respiration, may be resorted to. Burns, and injuries to nerve trunks are to be treated at a later stage by appropriate dressings and massage or a weak continuous current.

The experiments of Oliver and Bolam have demonstrated that death from exposure to high electrical currents arises from the effect of the current upon the heart and vessels, the respiratory movements often continuing for some time after the heart has ceased to beat. Hence the clear indication for artificial respiration persisted in for long periods, they have been able to restore animals to life after cessation of the cardiac contractions lasting 13 minutes. Sylvester's method and rhythmic traction of the tongue should be employed. From a study of the published cases one is led to hope that an immediate resort to the inhalation of Nitrite of Amyl may prove useful, and it is quite possible where the cardiac engorgement is well marked that bleeding might in some cases be worthy of a trial, especially as Bleile has found that the arteries are so constricted that the heart is unable to overcome the obstruction in front of it.

LITHIASIS—See Stone in the Kidney.

LIVER, Abscess of.

The ordinary pyæmic abscess is to be met by the treatment supposed to be useful in cases of pyæmia, but in the vast majority of cases it may be regarded as beyond the reach of art.

In cases where the abscess has resulted from tropical hepatitis, or where it has followed some ulceration in the intestines or stomach, as not very rarely occurs in this country, the affection is often susceptible to marked improvement or complete cure.

When seen before suppuration has occurred the hepatitis should be met by the remedies to be mentioned further on. When, however, the abscess has already formed, and the physical signs warrant a diagnosis of one large abscess, and not a series of small or multiple abscesses, the removal of the pus is justifiable. If the operator waits for a spontaneous opening he may see the patient sink from exhaustion or from rapid peritonitis, caused by the internal rupture of the abscess.

The operation is a simple one, and may be performed by thrusting in a moderately fine trochar and canula into the swelling, and evacuating its contents by a Dieulafoy's aspirator. Unless the

abscess be of very great dimensions it may be completely emptied at once. There is often no necessity for the insertion of a drainage tube. The writer has seen one tapping cure the condition. Some operators prefer to secure adhesion between the abdominal walls and the sac of the abscess by the local application of Caustic Potash or Lime before tapping. This is seldom necessary when a fine trochar is used, or when the puncture is made in an intercostal space.

Where there is reason to suspect that a second abscess exists after the first has been tapped, the trochar and canula may be withdrawn and inserted in another situation, and it has been over and over again proved that puncture of the liver in this way does not lead to any trouble, but that it has been the means of relieving acute hepatitis where no suppuration had occurred.

The puncture should be made at any spot where the physical signs show that pointing would likely occur if left alone. As a rule, the puncture below the ribs is better than in an intercostal space.

Hepatotomy has been several times performed successfully in urgent cases by opening the abdomen freely over the most prominent part of the tumour, which is then tapped, the abscess cavity freely opened, and its edges or lips sutured to the margins of the skin wound, after which thorough drainage is established, and suitable dressings applied. Excision of portions of one or more ribs may be required. (See under Hydatids, page 423.) Some surgeons disapprove of aspiration, and after making a free incision over the hepatic swelling, if they find adhesions have formed they recommend a free incision along the track of the exploring needle and insert a large drainage tube, but if no adhesions have formed it is recommended to insert a ring of sutures, fastening the surface of the liver to the parietal peritoneum, and after about 60 hours the abscess may be freely opened in the middle of the circle of sutures by the knife or thermo-cautery. This is the best operation for the amœbic abscess.

Manson's operation is a simple one; he makes certain of the presence of pus by the aspirator, then through a small abdominal wound he inserts a special form of canula and trochar into the abscess cavity. Through the canula he pushes a stout drainage tube stretched on a stilette. On the withdrawal of both stilette and canula the pus flows through the drainage tube, which must be large enough to quite fill the original wound. Several feet of tubing is then attached and the abscess cavity emptied by syphonage.

LIVER, Amyloid Disease of.

Under the heading of Bright's Disease, upon page 91, the treatment of amyloid disease of the kidney is briefly described. For amyloid liver, which so often coincides with renal change, the

treatment is the same, and may be briefly summed up in the removal of the cause when possible. Syphilis, pulmonary suppuration, bone disease, or chronic abscess, if remedied in the early stage, may be followed by the complete restoration of the disorganised kidney or liver. In the later stages palliation of the symptoms is the most that can be thought of. Of internal remedies, Iodine or Iodides, with full doses of Iron, afford the best advantages which can be hoped for from drugs. In syphilitic cases large doses of Iodide of Potassium (30 grs. three or four times a day) for long periods often give astonishing results. Life may be prolonged by a sojourn at a dry and elevated spot near the coast, and a long sea voyage is beneficial. The natural Iodine mineral waters may be tried with much advantage, and, in conjunction with these, large doses (30 grs.) of the Chloride of Ammonium may be administered.

LIVER, Acute Atrophy of.

The treatment of this affection may almost be regarded as hopeless, as the disease is generally fatal within 20 days. Where a case has been reported as a success after the administration of any remedies, the general tendency has been to regard it as an instance of mistaken diagnosis, though Hunter records the details of some cases which recovered. Success has been attributed to copious purgation by salines, even in fatal cases marked temporary improvement has been observed by this method of treatment. Hence in a disease so formidable saline purgatives may well have an extended trial. Those who maintain that the disease is produced by a microbe advocate the use of such agents as the Sulphocarbulates and large doses of Quinine.

When cerebral symptoms or coma supervene purgation should be pushed as far as possible, and the treatment (detailed under Bright's Disease) suitable to uræmic poisoning should be vigorously carried out. High temperature may be treated by large doses of Quinine, or by the newer Antipyretics, and symptoms as they arise should be met by remedies administered upon general principles.

LIVER, Cancer of.

All treatment can at the most be palliative, and is to be carried out upon general principles. Thus pain is to be relieved by Opium, constipation by enemata or mild cathartics, vomiting by Ice, Morphia Perules ($\frac{1}{4}$ gr. each), and counter-irritation, and the collection of fluid in the peritoneal cavity must be removed by tapping when the symptoms become urgent.

Under Cancer of the Liver, upon page 121, the case where Lücke excised the diseased mass is referred to. Tricome has also successfully excised the entire left lobe. Tansini, Mayo Robson, and others have also removed portions of the gland. Bianchi, by

means of two strips of perforated whalebone, circumscribes the portion of hepatic tissue before removing the tumour, sutures having been passed between the liver substance and the perforations in the whalebone to prevent hæmorrhage.

Fillipini recently reports two cases successfully performed, and he points to the ease and rapidity with which the left lobe can be removed. In severe cases he advises ligature of the pedicle by an elastic band and extra peritoneal fixation to prevent hæmorrhage.

LIVER, Cirrhosis of.

Under Ascites, the treatment of this malady has been briefly mentioned. As it occurs in the great majority of instances amongst "spirit-drinkers, the first step in treatment is to operate very decisively upon the cause. Alcohol, in every form, should be forbidden. Where it is found impossible to carry out this rule, the physician should insist upon whatever alcoholic liquor the patient indulges in being very largely diluted, and taken after meals. The extent to which the disease may yield, even when established beyond doubt, is rather under-estimated. The writer has had considerable experience of it, especially amongst the male operatives in large linen manufactories, where a very common practice amongst the "hacklers" of flax is to drink undiluted whiskey before commencing their daily work in the early morning, previous to breakfast, in order to relieve the chronic bronchitis and emphysema which almost constantly result from the nature of their employment, which necessitates their being in an atmosphere of fine flax dust. Where relief can be obtained by suitable bronchial remedies, and the hackler or flax-dresser can be made to give up his dram-drinking, permanent improvement sets in in the cirrhotic liver. Change of occupation is of vital importance in dealing with cirrhosis in publicans, barmen, and waiters. It is almost impossible for such men to abstain, once they have become enslaved to alcohol, unless a new sphere of labour be opened up to them.

Active open-air exercise or labour is of great importance, and the diet should be plain and nutritious. Attention should be paid to the amount of liquids imbibed. Where there is as yet no sign of effusion into the peritoneal cavity, a liberal allowance of liquid food is very desirable. Milk may be taken in large amount mixed with an equal quantity of aerated water, and the best diet is a liberal fish dinner and breakfast. A few months of vegetarian living often give excellent results. In Ireland, buttermilk or the home-made koumiss, mentioned upon page 26, affords a most valuable dietary. Yeo points out the importance of a diet consisting largely of milk mixed with an alkaline water like Vichy, Vals, or Apollinaris. This can be easily carried out by directing the patient to dilute his milk with kali water.

Purgatives are useful at all stages of cirrhosis, and saline cathartics as Epsom or Carlsbad Salts and the various purgative mineral waters are the best. Where the patient's means permit a sojourn at Carlsbad, Vichy, Kissingen, or Marienbad is very valuable. By an occasional dose of Blue Pill given at bed-time followed by a morning saline, the portal system is very powerfully influenced. Mercurials should be avoided where there is any renal mischief associated with the hepatic lesion. Podophyllin or Iridin may then be employed.

By the daily administration of one large saline draught before breakfast, following the occasional dose of podophyllin or a mild mercurial, marked diminution may be repeatedly observed in the liver in those cases where considerable enlargement, with induration, accompanies or precedes the fibroid change in the organ. Mercury may also be given for about a month in small doses alternating with large doses of Iodide of Potassium, administered for a similar period. This latter drug is of great value in syphilitic cases, there seems little reason to doubt that syphilis and malaria may be the cause of cirrhosis in a small percentage of cases. For the cases in which malaria is suspected, Quinine and Arsenic should be persisted in. Murchison attached importance to the action of the Chloride of Ammonium and Green Iodide of Mercury in ordinary alcoholic cirrhosis ($\frac{1}{2}$ to 1 grain, three times a day). These remedies, in the great majority of cases, cannot be pushed with safety, especially as most of the victims of cirrhosis are suffering from gastric troubles. Many of them are debilitated from want of common food having long since ceased to live with regularity and prudence. In such cases there is no remedy so frequently applicable as the Diluted Nitro-Hydrochloric Acid in full doses, combined with a vegetable bitter in small amount. It may, moreover, be given at the earliest and is often grateful during the later stages of the disease. As this acid is liable to decomposition, it is very often disappointing and fails to give any evidence of therapeutic power. It should consequently be seen that the specimen be of moderate age, and that it has been carefully preserved in a stoppered bottle. The Nitro-Hydrochloric Acid bath is prepared by mixing 1 oz. of strong Nitric and 2 ozs. of Hydrochloric Acid in 2 gallons of warm water. A local pack may be administered by soaking cloths in this mixture and applying them to the abdomen and lower part of the chest. The writer, however, prefers to apply the acid mixture in the above strength upon spongio-piline worn under a bandage over the entire hepatic region. As soon as any eruption appears the acid may be discontinued, but in some cases the mild counter-irritation produced by covering the acid lotion with an impervious tissue is productive of benefit.

The following is a good combination, it acts directly upon the liver, and at the same time tends to relieve the craving for alcoholic stimulants:—

R. *Acidi Nit.-Hyd. Dil.* ℥ss.
 Succi Taraxaci ℥ij.
 Tinct. Nuc. Vomica ℥v.
 Extract. Cinchonæ Liq. ℥iiss
 Infus. Chiratae ad ℥xij misce.

Fiat mistura. *Signa*—"A table-spoonful in a wine-glassful of water to be taken four times a day before food."

In a few cases the Chloride of Gold has been credited with causing absorption of the new fibrous growth.

When, notwithstanding the change in the patient's habits and the use of the above remedies, ascites sets in, the remedies are to be continued. Cure is still not beyond hope; and the writer has seen recovery follow where tapping had been deemed necessary. In a very small percentage of cases it appears that tapping may be even curative, and it should be resorted to early. The treatment of ascites will be found fully detailed under its own heading upon page 62, where the new operation for the cure of cirrhosis is referred to, i.e., the suturing of the liver and omentum to the abdominal wall with the view of readjusting the circulation through the new vessels formed in the resulting adhesions.

Vomiting may be met by counter-irritation over the gastric region, with Ice, and effervescing mixtures internally. Bismuth, Alkalies, Hydrocyanic Acid, and Morphia Perules $\frac{1}{4}$ grain each may be tried. Papan or Pepsin is useful in some cases, and peptonised food often may be very valuable when the condition of the gastric membrane is much deranged. Hæmorrhage from the bowels, hæmorrhoids, diarrhoea, and other complications are to be regarded as more or less conservative, and not to be interfered with too soon.

When hæmatemesis is sufficiently serious as to demand interference, the remedies indicated are enumerated under Hæmatemesis upon page 345. Death not unfrequently occurs from the rupture of varicose veins situated at the lower end of the gullet, and for which treatment is of little avail.

LIVER COLIC—See Gall Stones and Jaundice.

LIVER, Congestion or Inflammation of.

Where this is owing to valvular affection of the heart, the appropriate treatment will be found mentioned under Heart Disease, page 389.

In active congestion or hepatitis from indiscretions in diet, malaria, chills, &c., the cause is likewise to be as far as possible removed, after which rest, milk diet, a moderate dose of Calomel, followed by purgatives of the saline class, smart counter-irritation,

the mineral acids, especially the Dilute Nitro-Hydrochloric Chloride of Ammonium, Ipecacuanha in full doses, and in severe cases leeches to the margin of the anus, may be employed.

LIVER, Hydatids of—See Hydatids (Page 421).

LIVER, Injuries and Rupture of.

Absolute rest in the horizontal position, and after the symptoms of shock and collapse have been met by appropriate remedies a full dose of Morphia hypodermically may be administered. When there is reason to suspect that hæmorrhage into the peritoneal cavity is occurring, ice or Leiter's tubes should be applied over the hypochondriac region. Should symptoms of hæmorrhage still continue prompt laparotomy offers the only chance of recovery.

Waring insists upon—(1) Clearing out of all clots. (2) Application of a clamp to the hepatic artery and portal vein. (3) Ligation of any vessels that can be seen bleeding on the torn surface. (4) Suture of the wound in the liver by catgut sutures introduced by a blunt-pointed curved needle. If the margins of the rupture cannot be brought together, then the rent must be packed with sterilised gauze.

Under treatment by early laparotomy the mortality from wounds of the liver has been reduced from 88 to 28 per cent. (Terrier and Auvray). The intense thirst which is often a prominent and distressing symptom is best relieved by sucking small pieces of ice and swallowing small doses of Champagne.

Peritonitis, when it develops, is to be met by cold applications or warm poultices, Opium, and the remedies mentioned under Peritonitis.

LIVER, Syphilitic Disease of.

The treatment of this affection will consist in the persistent use of the remedies indicated in the treatment of the later stages of syphilis—i.e., Mercury and Iodide of Potassium, the latter in large doses. Complications as pain, peritonitis, jaundice, vomiting, or ascites are to be dealt with upon the principles already mentioned.

LOCOMOTOR ATAXY.

The treatment of this affection is too often approached in a half-hearted fashion. Upon the authority of Erb at least two cases almost completely recovered under treatment, and Grassi regards the disease as curable. The writer has seen improvement take place which almost amounted to recovery in one case, and he had under observation a patient who had the disease in a well-marked degree for at least 25 years. In this case periodical treatment enabled the patient to hold a responsible position without any material increase in his ataxic symptoms. Gowers states that the treatment by drugs often has a very clear influence not only

in relieving suffering but in determining the arrest or diminution of the disease.

As long as locomotor ataxy is regarded as hopeless, the treatment will likely be carried out in such a way as will give very unsatisfactory results. No doubt improvement and long stationary periods in the progress of ataxia occur where no drugs have been given, nevertheless clinical experience confirms the view that drugs are often useful.

The patient should be placed in the most advantageous position possible, excess of mental and bodily fatigue being forbidden, regular hours, good nutritious food and warm flannel clothing from head to foot being recommended. Falls must be very carefully guarded against, and alcohol, tobacco, and sexual excesses undoubtedly aggravate the disease.

Of the long array of drugs vaunted from time to time as specifics only a few need be referred to, as the greater number of them have been found by large experience to be useless or injurious.

The Chloride of Gold and Sodium (U.S.P.) is the drug upon which the writer places most reliance. Bartholow believed that its administration tends to produce absorption or atrophy of the connective tissue, especially when of pathological formation. No discoloration follows its continuous use, and in doses of $\frac{1}{2}$ grain three times a day the writer has not found any drawbacks. It may be given best in pilular form, or in solution in distilled water, without the addition of any vegetable substances. Gowers states that Arsenic gives the best results of all drugs. When administered for periods of three months at a time, it may be alternated with the gold treatment.

Nitrate of Silver has been found by most authorities to exert a beneficial action upon the disease, but against it is the danger of causing permanent discoloration of a very serious kind. If given, therefore, it should only be for brief periods at a time, and in doses of not more than $\frac{1}{2}$ gr. in pill.

Phosphorus, Ergot, Calabar Bean or Eserine, Pilocarpine, Bromides, Chloride of Barium and of Aluminium, and Iodine may be tried where Gold and Silver fail to give amelioration of the symptoms, or where they cannot be tolerated.

Iodide of Potassium, in full doses (15 to 30 grains) three times a day, has often been found to cause marked improvement. It does not act as an antisyphilitic, for the writer has seen benefit from its administration where there was no reason to believe that syphilis had ever existed. Occasionally it will be found to produce marked influence for good over the lightning pains. Weiss and Stark have recently reported most marked improvement from daily doses of about 3 drachms.

The association between syphilis and ataxia is very close, and it has been stated that syphilis is a cause in 90 per cent. of cases. This is perhaps over-stated, but even where there is a close history

obtainable, the disease fails to respond to the ordinary antisyphilitic remedies.

Perchloride of Mercury is, nevertheless, worthy of a trial, and may be found not unfrequently to be followed by some steady improvement up to a certain point, after which it appears to be worse than useless to push it. This is also true of the Iodide treatment, whether there is or is not a syphilitic history. In one case of very long standing under the care of the writer there was a most extraordinary intolerance of even infinitesimal doses of the Iodide. This was probably a coincidence. Tonics, like the diluted Mineral Acids with Quinine, may be given from time to time during the pauses in the above-named drug treatment but there appears to be a general feeling against the routine administration of Strychnine, though occasionally benefit has been seen to follow its use by Gowers, who gives $\frac{1}{16}$ gr. Nitroglycerin with it, which he thinks causes the blood containing the alkaloid to pass more freely to the nerve centres. Erb's highly praised Tonic Pills consist of 1 gr. Lactate of Iron, $1\frac{1}{2}$ grs. Extract of Cinchona, and $\frac{1}{2}$ gr. Extract of Nux Vomica; one thrice daily. Reports about the value of the injection of various organic products as Brown-Sequard's Spermine, Cerebrin, Brain Extract, &c., must be received with caution, some observers stating that 90 per cent. of 'cures or ameliorations' have followed their use, whilst others deny any action whatever beyond what may be expected from the injection of ordinary saline solution. Massalongo affirms that any results observable are due to 'suggestion' and the influence of the imagination; quite inert matters gave equally brilliant results.

Outside the list of drugs there are remedial agents of value in the treatment of ataxia.

Electricity stands at the head of these. Rarely does its steady administration fail in producing some benefit, but, like all the previously mentioned methods of treatment, it leads to improvement up to a certain point, and when the symptoms seem stationary for a time, the patient tires of treatment till a fresh advance in his troubles urges him again to seek relief from the battery. The continuous current gives the best results.

One pole may be placed upon the upper part of the spine in the cervical region, and the other one over the lower lumbar spines, and the current from 15 to 20 Léclanché elements should be allowed to pass for about five minutes twice daily. A current, from 3 to 4 cells, should also be passed through the brain for a few minutes. A very good method is to place the positive pole upon the upper spines, and drop the negative into a warm or tepid foot-bath, in which both lower extremities are immersed for 5 or 10 minutes. Where the continuous current fails to afford any signs of improvement in the patient's condition, Faradic electricity has been employed, but it seldom will be found to be of any value. The Faradic brush has been favourably reported upon. In the

majority of cases the continuous current will be found to have some beneficial effect upon the frequency and intensity of the lightning pains. Where these are very severe, the current may be applied to give relief at the time by placing the positive electrode upon the painful region, and the negative upon some indifferent point.

Static electricity has also given good results, but the writer cannot speak from any experience of its action.

Hydropathy is of use in some cases, and may be carried out in conjunction with the gold treatment internally and with electricity. Cold packs, the combination of douche and massage, or spray and needle baths, with frictions and manipulations applied to the spine and lower extremities may be employed. All warm or hot baths must be forbidden, though Leyden recommends the free use of baths at 86° to 95° F., and also of brine baths.

Counter-irritation has been long tried, and it formerly was a common occurrence to find ataxic patients covered from the occiput to the heels with marks of old blisters and caustery irons. Brown-Sequard recommended this practice, and believed in its efficacy in cutting short the progress of the disease and relieving the various symptoms. It may be useful where there is much spinal tenderness, and in those cases where the ataxia has rapidly followed falls or concussions.

The method of suspension detailed in former editions of the present work has not been followed by anything like the benefits which its supporters alleged. Various theories of its action were elaborated, but it is useless to discuss them, since the cures and improvements which these theories were invented to explain are now themselves discredited.

Nevertheless it cannot be denied that great improvement in the ataxic and bladder symptoms often resulted, but most observers will agree that the ameliorations were very short-lived, and that the early prophecy of Gowers, "that it will also probably before long be forgotten," has already proved true.

Several deaths have been recorded from its unskilful application; it is contra-indicated in aneurism, phthisis, and obesity.

Bonuzzi has introduced the plan of forcible flexion of the spine as a substitute for suspension. It is carried out by forcibly pulling up the lower extremities as the patient lies upon his back with a towel tied round his ankles. Blondel has reported that the pains were speedily removed in a very severe case by placing the patient in a bed with his thighs flexed on the abdomen so that his knees approached the chin, the legs being flexed as much as possible. A cord was then passed round the neck and under the knees, and the position maintained for five minutes every night for eight nights. A complete cure is reported, and it is claimed that all the advantages of suspension are thus obtainable without danger. De La Tourette stretches the spine by fixing the pelvis and

strapping the legs to a narrow table, after which the spine is flexed by means of a cord and pulley fastened to a collar attached to the neck and shoulders.

Nerve-stretching has now been abandoned.

The method of educating the ataxic patient to perform various complicated muscular movements by means of guidance with his visual organs, all along regarded in this country as a necessary routine, has been developed into a "system" by Frenkel and Hirschberg, and great improvement in the ataxia has been reported.

The various symptoms of locomotor ataxy are to be met by appropriate remedies. Thus the action of Galvanism and Iodide of Potassium upon the lightning pains has already been referred to, but Antipyrine and Antifebrin are the best drugs for the relief of these pains. When they show signs of losing their effects, Phenacetin, Exalgin, Cocaine, Chloralamide, or Cannab. Ind. may be resorted to, or the more recent administration of Methylene Blue as advocated by Lemonie may be resorted to. Gowers believes that a recurrence of the paroxysms may be prevented by a course of the Chloride of Aluminum 3 grs. three times a day, but sometimes the hypodermic injection of Morphia must be resorted to. This must be only in very exceptional cases on account of the certainty of establishing the opium habit if the syringe be left in the patient's hands. The application of Ether Spray, Chloroform, or Menthol to the part often relieves.

Recently Negro reports success from the administration of Santonin in the crisis of lightning pains. He gives 10 grs., and in five hours later another 5 grs.

The gastric crisis is best met by smart counter-irritation, with Morphia hypodermically, followed by gastric sedatives.

Laryngeal spasm yields speedily to Amyl Nitrite.

Of all the symptoms or complications there are none so important as the bladder trouble, and the writer has had the satisfaction in more than one case of saving and prolonging life by the use of the catheter and the administration of antiseptics, especially of Boric Acid, Salol, and Creosote, for constant use this latter drug is invaluable. He observed its powerful influence upon the urine accidentally after it had been administered for stomach trouble. Strychnine, recommended by Gowers for bladder weakness, has always, in the experience of the writer, aggravated the lightning pains. An aseptic catheter, with occasional washing out of the bladder by warm Boric Acid solution, removes speedily all distress from cystitis caused by residual urine. Marie insists upon the value of Ergot in the urinary troubles of ataxia.

Perforating ulcer of the foot heals under Galvanism patiently applied two or three times a day with one pole on the thigh and the other in a warm salt foot-bath. This result is sometimes very striking.

LUMBAGO.

Large doses of Salicylate of Sodium, 30 to 40 grs. of the pure salt, may cut short the attack suddenly. Antipyrine or Antifebrin, in one or two full doses, sometimes gives marked relief in the same way. If pain is not speedily relieved by these measures, and if it is very severe, a hypodermic injection of Morphia may be given, and the salicylate treatment continued, or Salol may be tried. In less acute cases the favourite treatment has been also anti-rheumatic and almost every remedy of this class has been tried. *Actæa Racemosa* or *Cimicifuga*, in 30 minim doses of the liquid extract, may be given every four hours.

Large doses of Bicarbonate of Potash (1 drachm) in effervescence, with one ounce of fresh Lemon Juice, is an excellent routine treatment.

Ten gr. doses of the Nitrate of Potash in whey every two hours for three doses then every six hours may be tried.

The writer has been surprised sometimes to find that speedy and permanent relief followed one large dose (a good wine-glassful) of unsweetened Gin given in the form of punch, and he makes this his first step in the treatment of all severe and acute cases.

In chronic cases, where the above remedies have failed, Sulphur, Cinchonidine Salicylate, Ammonium Chloride, Quinine, Turpentine, Guaiacum, Iodide of Potassium, Guarana, and Caffeine have been used with varying success.

From the above list it will be evident that the constitutional treatment of lumbago is uncertain and the same experience will be found in the use of local or external remedies. What relieves promptly in one case will fail in the next or in the same patient at some future time. The hot air bath or the ordinary Turkish bath often gives relief. The warm bath is of little use, but a hot bath (temperature 106° F) generally is soothing. The Thermo-electric bath will probably prove very valuable.

Hot poultices are not so good as a local hot pack, with a warm douche or massage afterwards, or dry cupping.

When the above measures have been carried out a large thick pad of warm absorbent wool, sprinkled over with Sulphur should be applied to the painful region, and a firm broad flannel binder or bandage adjusted over it. Absolute rest in bed is then to be maintained, and the constitutional treatment with the above-mentioned remedies is to be kept up. Sedative liniments may be rubbed in or applied under oiled silk. The following is a valuable combination :—

- R. *Liniment. Belladonnæ* ℥ii.
 Liniment. Aconiti ℥iiss.
 Liniment. Chloroformi ℥iiss misce.

First applicatio. Signa—"To be sprinkled freely over lint, applied to the painful region, and covered with oiled silk."

Squire's Chloroform of Belladonna is also a powerful local sedative. The Belladonna Plaster, and the Belladonna Extract rubbed up with Glycerin, are often used, but they make a nastiness of the patient's clothing, and are in no way superior to the liniments. The Plaster of Belladonna mixed with an equal amount of the Plaster of Opium and spread upon leather, with a very wide non-adhesive margin, is, perhaps, the best local application when the patient begins to move about again. The back may be strapped with such a plaster when movement continues to cause very severe pain. The Ether Spray or the Spray of Chloride of Methyl often gives speedy relief, and Ice has been recommended as a local application, but its routine use is not to be advised.

Chloral Hydrate dissolved in the smallest quantity possible of water, and added to an equal bulk of Olive Oil, is useful as a sedative liniment rubbed in vigorously.

Counter-irritation is sometimes recommended at the commencement of the attack, though it is more useful at a later stage. Sinapisms are lauded, but the writer never used them without finding the pain and discomfort aggravated without any apparent benefits.

Chili Paste is a favourite counter-irritant, so also is strong Acetic Acid.

Acupuncture is undoubtedly of great value, and though a painful remedy it acts sometimes with surprising rapidity. It may be carried out by using the multiple puncture apparatus, or by rapidly inserting a stout needle for about an inch into the affected region, at right angles to the surface, and withdrawing it quickly. A dozen or more punctures may be made on each side of the spine.

Aquapuncture may be carried out in the same way, with the ordinary hypodermic needle, and a little pure water injected each time.

Carbolic Acid has been injected instead of the plain water, in some cases, with advantage, and so has Nitrite of Amyl, in minute doses, dissolved in 10 min. Spirit.

Blisters may be applied in chronic cases, or the actual cautery may be used in the form of Corrigan's Iron, lightly and quickly pressed against the skin, so as to cause a very superficial eschar. The thermic hammer may also be used. One of the best methods of treating acute lumbago is to cover over the affected region with a piece of stout brown wrapping paper, and pass slowly and firmly over this a very warm smoothing iron, such as is used by laundresses, till the patient ceases to be able to tolerate the heat. The writer has seen this to speedily dissipate all the symptoms of pain, stiffness, &c.

Of stimulating or mild counter-irritating liniments there is no end, thus Camphor, Paraffin Oil, Turpentine, Eucalyptus, Rhos, and others are useful.

Electricity is of considerable value in the treatment of lumbago. Occasionally speedy disappearance of all pain has been found to follow the early application of a moderately strong continuous current. It is the best routine treatment in chronic or recurring cases when combined with massage, and the judicious use of warm bathing at resorts like Bath, Strathpeffer, Droitwich, Harrogate, Baden-Baden, Aix-la-Chapelle, Contrexeville, Marienbad, &c.

LUNG, Abscess of.

The diet should be of the most sustaining; the surroundings of the patient should be such as will give the best chance of recovery in any wasting pulmonary disease. The same rules for ventilation, pure air, climatic treatment, &c., may be tried in chronic cases as are indicated in phthisis.

The tendency to bring abscesses and cavities in the lung under the dominion of the surgeon is steadily on the increase. Many failures from operative interference have occurred, and some successes have been reported. There is, however, sufficient progress made to justify fair hopes that the treatment of basilar cavities will become as satisfactory as is the management of empyema.

Tuffier has collected 43 operations by incision—of these 33 resulted in complete cure, and 10 died.

Various means have been tried, the simplest is to make a free incision through the tissues in the chest wall, resect a portion of one, two, or three ribs, divide the healthy lung tissue slowly by means of the thermo-cautery till the abscess cavity is reached, and after the evacuation of all pus and debris to ensure thorough drainage as in a localised empyema. Where there is complete adhesion of the pulmonary and parietal pleura the operation is comparatively free from danger, and some authorities secure this by the preliminary application of caustics before performing pneumonotomy. Some few cases have been reported where a large trochar and canula thrust into the abscess cavity between the ribs has given enough room for the introduction of a sufficiently wide drainage tube. The most suitable cases are those where the disease is confined to the lower lobe of one lung, and where the pleura is adherent. Such cases, whether consisting of simple abscess, gangrenous abscess, or bronchiectasis, are easily treated by this simple method. Afterwards the cavity can be washed out with warm antiseptic solutions. (See also under Empyema.)

The aspiration of the abscess or the injection of antiseptics like Carbolic Acid, Creosote, Perchloride of Mercury, Iodoform, &c., into the abscess cavity without previous pneumonotomy seldom leads to satisfactory results. Internal remedies have little effect, save those which improve the appetite and digestion, lessen fever, and reduce hectic. Creosote or Eucalyptus, in full doses, some-

times does much good by diminishing or retarding the putrefactive changes in the cavity when operative interference is contra-indicated. Volatile antiseptic inhalations or sprays may be useful. See under next article.

LUNG, Diseases of—See Phthisis, Emphysema, Pneumonia, Asthma, Hydatids, Bronchitis, &c.

LUNG, Gangrene of.

Practically the management of this condition will correspond with the treatment of bronchiectasis detailed upon page 93. Thus whilst every means is being employed to keep up the patient's strength and to improve the state of his nutrition measures should be taken to diminish, as far as possible, the indescribable fetor or stench which surrounds him. This may be attempted by the administration of volatile antiseptics internally and by the saturation of the surrounding atmosphere with similar agents. Creosote in doses of 2 to 5 minims, in an emulsion or in capsular form, is the best. Turpentine, Myrtol, Oil of Santal or of Eucalyptus or of Peppermint, are also useful. Carbolic Acid cannot be given internally for any considerable period of time with safety in doses sufficiently large for this purpose. Sulpho-carbolates have been found to diminish the abominable odour from the perspiration.

These volatile antiseptics, as they are excreted by the pulmonary or bronchial surface, afford the best chance of modifying the diseased action. See reference to the Garlic treatment under Bronchiectasis.

The air of the room may be kept saturated with Oil of Turpentine. This may be accomplished by periodically pouring some of the oil upon the surface of very hot or boiling water, but the rapid evaporation or vaporization of the turpentine soon ceases, as the temperature of the water falls. The writer's plan is to fill metallic trays or pans half full of dry pine sawdust, upon which the oil is to be freely sprinkled from time to time. A uniform degree of evaporation may be thus obtained. A good method which he has also tried with satisfactory results is to make a muslin or gauze coverlet, and fill it with freshly teased out oakum. This may be kept upon the patient's bed, and the oakum can be easily renewed, or sprinkled over with Turpentine, Eucalyptus Oil, or other volatile antiseptic from time to time.

Chlorinated Lime, Bromine, Chlorine, Sulphurous Acid, Commercial Terebene, Sanitas, or any of the innumerable cheap disinfectants may be used for the same purpose. A spray apparatus may be employed to diffuse the disinfectant through the room.

Of local remedies brought to bear upon the gangrenous region, any of the forms of antiseptic inhalations may be employed. Thus the vapour arising from Eucalyptus, Menthol, Iodine, Chlorine,

Creosote, Carbolic Acid, &c., may be breathed from any of the ordinary earthenware inhalers. As a rule, however, in an affection like the present these are worthless. Where a very thorough disinfectant action is required, the volatile ingredient may be poured upon boiling water contained in a large wash basin, as the patient holds his head over it, whilst a linen sheet is thrown loosely over him so as to extemporise a tent, under which the concentrated vapour may be freely breathed at intervals of a few hours during the day.

It will not be found practicable to keep the atmosphere of the room impregnated with the vapour of the remedy to such a degree as to affect the secretions at the diseased spot in the lung, else no further inhalations or sprays would be necessary beyond the turpentine or other disinfectant used to purify the air of the patient's chamber. It is thus essential that occasionally the remedies be employed in a more concentrated form, as just mentioned, by steaming under a sheet. In the intervals between these steamings, he breathes day and night the more diluted medicated atmosphere of his room. The value of Chaplin's Creosote chamber, as detailed under Bronchiectasis, in modifying the fetor must not be lost sight of. It will probably prove to be the best means of treating gangrene of the lung.

Sprays are of considerable use and are less troublesome, though of less efficacy, than the steaming under a sheet, by their use particles of a solution containing non-volatile ingredients may be projected in a state of minute subdivision, so that they may come into contact with putrefying secretions about the naso-pharynx, larynx, and larger air tubes. The following solutions may be used as sprays:—

Bichloride of Mercury, 1-2 grains in 10 oz., Solution of Chlorinated Lime, Solution of Chlorinated Soda, and Sulphurous Acid, each 1 in 20. Creosote or Carbolic Acid 1 drachm in 10 oz., Bismuthide of Mercury, 1-2 grains dissolved with K I, in 10 oz. water, Creolin, 1-5 per cent. solutions in water.

By the use of the perforated zinc inhalation respirator of Yeo, worn for a shorter or longer period during the day, many remedies may be brought into contact with the air passages. In this way the following substances may be employed—Iodine, Creosote, Terpinol, Terpene, Terebene, Eucalyptus, Carbolic Acid, Iodoform, Thymol, Menthol, &c.

The following is a good inhaling fluid for sprinkling upon the lint or cotton wool of the inhaler:—

- R. *Creosoli Purificati* ℥ij.
 Menthol ℥ii.
 Thymol ℥ss.
 Spir. Vini Rect. ad ℥iv. *misce.*

Pure Creosote or any of these solutions may be used in an Oppenheimer's Nebulizer.

The method of intra-laryngeal injection, as mentioned upon page 95, may be tried, and the same solution, *i.e.*, Menthol and Guaiacol, in Olive Oil, may be used. The injection of Antiseptics through the chest wall into the gangrenous cavity has not been satisfactory.

The expectoration should be passed directly into a spittoon containing some powerful disinfectant and deodoriser like Turpentine, Eucalyptus, Chlorinated Lime, or Permanganate of Potassium in strong solution. It is only by rigid attention to these details that the abominable fetor can be so diminished as to permit the nurse and attendant to approach the patient closely. When the physical signs reveal a gangrenous abscess cavity, the operation of cutting down upon it, performing pneumonotomy with the galvanocautery or scalpel, evacuating its contents, blowing in a dry antiseptic powder like Boracic Acid after washing it out most thoroughly with Corrosive Sublimate Solution, and establishing free drainage, is the best procedure.

Herzfel recommends operation in most cases of gangrene. He gives the results of 91 recorded operations, showing 60 successes. He states that expectant treatment is practically always fatal, and therefore no longer justifiable. Free removal of ribs is always necessary.

LUNG, Inflammation of—See Pneumonia.

LUNG, Passive Congestion of—See Treatment under Heart, Valvular Diseases of.

LUNG, Œdema of.

As this is secondary to valvular disease of the heart or to Bright's disease, or merely as a local result of a general anasarca, its treatment is already detailed under the name of the primary affection. The chief indication in the treatment in the majority of cases is to stimulate the heart with Strychnine and Digitalis. As much as 10 mins. of the B.P. Liquor of Strychnine may be injected in a desperate case. In the acute form associated with dilatation of the right ventricle a large vein should be opened and 10 oz. blood removed, or wet cupping over the back of the chest if rapidly carried out may save life in apparently hopeless cases. Nothnagel advocates one large blister, and the hypodermic injection of Camphorated Oil. This may be administered in 15 minim doses *ter die* of a 20 per cent. solution in Olive Oil.

LUNG, Wounds of.

The less interference in these cases, as a rule, the better, the probing for bullets, &c., or examinations to determine the depth of the wound are unjustifiable. Perfect rest in an easy position, with the patient lying upon the wounded side, and where there is much

hæmorrhage the insertion of a good drainage tube and the dressing of the wound with a large pad of Carbolie gauze fastened by a moderately tight broad bandage passed round the thorax, is all that is generally required. If the lung be not compressed already by pleural effusion, or blood, strapping of the chest relieves pain and distress. When the chest becomes filled with blood, aspiration may be tried as soon as there is reason to believe that the internal hæmorrhage has ceased, if air has been previously admitted, and suppuration has taken place, a free opening, and treatment as for empyema must be resorted to.

Complications as pneumonia, hæmothorax, pleuritis, emphysema, empyema, acute bronchitis, &c., are to be treated upon the principles laid down under their several headings.

LUPUS ERYTHEMATOSUS.

This disease is little influenced by remedies, notwithstanding the enormous mass of its therapeutic literature.

Whilst any departure from the healthy standard is to be carefully sought out and treated upon general principles, every means should be utilised whereby the general nutrition of the body is to be improved, and the general indications in this respect will be those mentioned under Scrofula, Phthisis, &c.

Of internal remedies some have been reported as followed by complete and permanent cure, and the list of constitutional specifics for lupus erythematosus is already very large and still increases. When it is remembered that in a small proportion of cases the affection disappears when left to itself it can be readily seen that the apparent cures probably owe little to the remedy which has been employed.

Of the remedies accredited with curative powers Arsenic stands first, and since in small doses it may be given for long periods without doing any harm it may be employed in every case where there are no contra-indications. Some of the highest authorities have reported permanent improvements in a few cases as resulting from its prolonged administration, though the experience of every physician proves how useless it is in the vast majority of typical instances of the disease.

Quinine has been vaunted as curative, and Reichel has recorded several cases cured by comparatively short courses of this drug in full doses.

Phosphorus has long been recommended, and within the past few years its use has been revived and several satisfactory reports have been made of cases treated by it. Bulkley lauds it in doses of $\frac{1}{16}$ to $\frac{1}{8}$ gr three times a day in solution. Ichthyol has been credited with reducing hyperæmia when given internally.

Iodine (free) or Iodides of Iron, Starch or Potassium, Iodoform, Carbolic Acid, minute doses of Mercury, Ergotin, Iron preparations, and last, though perhaps the only valuable member of the group, is Cod Liver Oil. Indeed, it will be a wise plan, if this affection is to

receive any chance of improvement from internal remedies to make a rule of giving the drug selected in combination in conjunction with Cod Liver Oil. Thus 5 minims of phosphated oil in a dessert- or table-spoonful of cod liver oil twice daily for a month, followed by arsenic for a month, and again resuming the oils, is the best internal treatment.

The local treatment of lupus erythematosus is a difficult subject in the limited space of a short article like the present, especially as a survey of its literature would almost lead one to conclude that nearly every known inorganic remedy had been recommended to its destruction at some time or other. This is the more remarkable as the affection is a comparatively rare one.

Another inherent difficulty, apart from the extraordinary multiplicity of so-called remedies, is the task of giving a clear idea of the agents indicated at the different stages and variations of the disease without a minute description of these stages which vary almost every instance. These remarks apply with more or less truth to the treatment of true lupus also. As stated by Pye-Smith the treatment of erythematous lupus is that of the milder forms of lupus vulgaris, stimulating applications generally taking the place of destructive measures.

Some cures have recently been reported from Finsen's method of exposing the diseased surface to the action of the chemico-luminescent light (see page 536), and success is also reported from exposure to the X Rays. Attempts have recently been made to subject the patches to the action of electric currents of high frequency but the difficulty of forming an estimate of the value of any recent treatment from the published reports is great owing to the liability to relapse.

In the early or erythematous stage, soothing lotions or ointments are indicated to relieve congestion and pain. Speaking generally cases at this period of the disease may receive the treatment most useful in acute eczema. Thus a bland, unirritating ointment, such as the B.P. Ungt. Zinci, to which Liq. Plumbi Fort. (1 in 20) is added, or a cream or paste made by rubbing up the Oxide of Zinc with Olive Oil may be smeared over the parts with a brush several times a day. A weak Lead lotion (1 in 20), Lime water or Carbolic Lotion (1 in 40) may be applied under oiled silk.

M. Morris states that in the early stage, with much hyperæmia there is no drug gives such good results as Ichthyol in the form of lotion or ointment, or as zinc ichthyol salve-mull applied at night after bathing the parts with hot water.

Collodion painted constantly over the part and permitted to dry causes compression of the vessels and, provided one layer be added before the cracking or peeling of the former one renders its action void, a continuous action may be kept up which, with great care and patience, may prove valuable. It protects the parts from changes of temperature, and, by the compression of the tissue, may

promote the absorption of effused products, or starve out the small celled growth in the connective tissue.

At a later stage stimulating applications may be tried, but in this sometimes a difficulty presents itself, one part of the patch being distinctly erythematous, whilst the other shows infiltration or scarring. Tarry compounds are very valuable, and, if persisted in at this stage, may give good results. The most suitable is an ointment varying in strength from half to two drachms of the *Liquor Carbonis Detergens* to 1 oz. of Lanoline. When this fails the next best method of treatment will consist in the application of the B.P. *Unguentum Hydrargyri* or a 10 per cent. ointment of the Oleate of Mercury upon lint, which should be kept in contact with the part constantly.

Carbolic Acid, in the form of an ointment (1 in 10) may be applied, and when at a later stage it is decided to destroy the growth, the acid may be painted on in its purity. Naphthol, Chrysophanic Acid, Resorcin, Mercurial Plaster as strongly recommended by Kaposi, green or soft Soap, Sulphur Ointment, Iodine as tincture, ointment, or glycerin, or Fowler's Solution brushed on daily may be tried.

Pyrogallie Acid applied in the form of a 10 per cent. ointment for 3 or 4 days till the brown eschar forms, after the separation of which iodoform ointment and guaze is used, is advocated by Verel.

Chicken has obtained excellent results by nascent Sulphur, which he generates in the patch by applying Condyl's Fluid, followed by Sodium Hyposulphite and Dilute HCl.

Where absorbent or stimulating applications fail, and the disease continues to progress, the destruction of the new growth by stronger remedies is to be seriously considered, and much caution and some skill is requisite in carrying out this in order to prevent such a free destruction of tissue as may result in a more unsightly appearance than if the affection was left to itself.

Any of the caustics recommended for the destruction of tissue in lupus vulgaris may be tried. Thus Creosote, Salicylic, Carbolic, Acetic, or Lactic Acids, Chloride of Zinc, Solid Nitrate of Silver, Permanganate of Potassium, Corrosive Sublimate, Pernitrate of Mercury Solution, or surgical procedure with the spoon, cautery, or galvano-cautery may be resorted to.

The safest and least disfiguring method of treatment is that by Squire's linear multiple incisions or scarifications made by a suitable instrument. With great care these incisions may be made with the point of a fine, very sharp scalpel or tenotomy knife, so as to leave the healthy skin untouched. The object of these minute incisions or punctures is to cause destruction of new vessels, and so starve out the growth and cause its absorption. The punctures should not exceed $\frac{1}{4}$ inch in depth, and they should be as close together as possible; afterwards a strong Iodoform ointment should be rubbed in.

LUPUS VULGARIS.

The same drugs which have been supposed to exert a specific action in the erythematous variety of lupus may receive a fair trial. These are—Cod Liver Oil, Arsenic, Phosphorus, Iodine, Iodoform, Creosote, and the various preparations of Iron. Though they are useless as regards a cure of the disease, nevertheless they are valuable as adjuncts in combating the constitutional tendency after radical surgical procedures have been undertaken.

Hutchinson lays great stress upon the importance of constitutional treatment directed to improving the general health, and upon the necessity of protecting the seat of the disease from cold and damp in winter. He therefore recommends the lupus patient to keep in warm rooms in the winter, or to change his residence so as to enjoy perpetual summer.

Of internal agents supposed to have a local action after their absorption, Koch's modified Tuberculin gave great hopes, but now this method has practically fallen into disuse. The same can be said of the Cantharidinate of Potash injections, and of the method of injecting Dog's Serum, though the writer has witnessed some very striking results from this agent in the hands of Fournier working in conjunction with Ricket. Thyroid feeding, as recommended by Bramwell, has not realized the high hopes arising from the early published cases, nor has the injection of Antistreptococcic Serum or inoculation with Erysipelas virus found favour.

Attempts have been made in the early stages before ulceration has occurred to kill and cause the absorption of the bacilli and cells by rubbing in Mercurial preparations, Iodine, &c., or by applying ice for two or three hours daily.

All local treatments have this in common, that their rationale depends upon the recognition of lupus as a local tuberculosis of the skin. Before ulceration has set in some recommend soothing applications, as Zinc Ointment, Lead Lotions, &c., as in the erythematous variety, but no hope need be indulged in that such measures can do anything but give very temporary relief. They are necessary however in various stages of the advanced disease, in order to subdue the smarting and congestion which hover about the circumferential zone of the affected patches.

Recently Finsen's Phototherapy has given most satisfactory results, some of which are very remarkable. The method is based upon the demonstrated fact that the chemic rays (blue violet, and ultra-violet) are bactericidal. Strong sun light, concentrated and cooled, or artificial light (electric arc), may be employed. Where the disease is very rebellious this plan can be combined with other procedures, and the Pyrogallic Acid Ointment has worked well in conjunction with it. No attempt need be made here to describe the details of this plan of treatment, as it at present should be confined to those who have given it very special study and practice. The complete installation costs about £200. The light from the electric arc is concentrated by lenses of quartz

mounted in telescopic fashion. Glass lenses are used in the concentration of solar light, and the rays are cooled in their passage through the lens, which contains a blue liquid (ammoniacal copper sulphate). The treatment is very slow, many months being necessary, and the sittings extend from an hour, according to the extent and depth of the lesions, &c. The treatment is practically painless, and the scar is everything that can be desired. This new plan promises to become the future treatment of this hitherto formidable disease.

The application of Hot Air (300°) by Hollander's method, under general anaesthesia, is still reported of favourably.

The X Rays have been utilised in the treatment of lupus, but as yet the results are not conclusive, and it has not yet been proved that the rays are really bactericidal.

The different treatments aiming at the destruction of the tubercular nodules, by solvent substances, are already very numerous, and the result has been the introduction of quite a number of methods, for which is claimed that by their use the diseased elements of the skin are effectually destroyed without the least injury to the healthy constituents of this tissue. The great object being the destruction of the diseased cell growth, this can be more easily, rapidly, and certainly accomplished by surgical methods, but as the chief site of the affection is upon the face, the nature and extent of the resulting scar is a matter of the greatest moment to the patient. Hence any agent which will select out the new growth and accomplish its annihilation with the minimum loss of healthy tissue will be of the greatest value, even though the process be a tedious one. These agents are, however, sometimes uncertain in their action, especially where the disease is extensive, but they are often very successful in dealing with small patches, and, though the operator need not expect to get the speedy and complete triumph which a perusal of the recent literature of lupus would lead him to believe is awaiting a trial of these remedies upon the first case which he meets, nevertheless in the great majority of instances ultimate success will follow a steady, persevering application of most of the members of this class.

The most typical member of the group is Salicylic Acid. It is best used as a paste, which can be made by rubbing up the pure acid with Creosote in about equal proportions. Where an extensive ulcerated surface upon the face is to be operated upon with this paste, the ulcers should be previously freely brushed over and covered with a piece of lint soaked in a strong solution of Cocaine (10 to 20 per cent.). The paste can then be applied daily till a raw granulating surface is seen to occupy each spot where the tubercles or ulcers had formerly flourished.

Unna's "Plaster Muls," containing Salicylic Acid and Creosote, are much more elegant and efficacious agents. The ointment form is preferred. The following is a good formula—it should be

spread on lint and covered with gutta-percha.—Creosote, 1; Salicylic Acid, 1, and Simple Ointment, 2.

No rule can be laid down for the number of applications. The physician should not begin the treatment unless he has made up his mind to the trouble and slowness of the process. The writer has seen a considerable patch treated by this method get perfectly healed up inside three months. Whatever objections may be made upon the score of delay are often answered by the satisfactory nature of the resulting scar. As will be mentioned later on this paste is of unquestionable value in very obstinate cases when applied after surgical measures have been employed to remove the diseased tissue in bulk.

Morris strongly approves of Brookes Ointment, rubbed in vigorously every night, the parts being afterwards dredged with Potato Starch Powder. The following is the formula.—

R *Acid. Salicylic.* gr. xl.
 Lithyol min. xl.
 Zinc Ox. et Pulv. Amyli ana ʒss.
 Vaselin. Alb ʒj
 Hydrarg. Oleat. (5 per cent) ʒii.
 Olei Lavandulæ q. s. misce

Lactic Acid is another remedy which there is good reason for believing may cause destruction of the diseased cell growth without injuring the healthy skin. The concentrated acid only should be used, and, owing to its thick, syrupy consistence, there is not any great difficulty in limiting its action to a particular spot. The writer has used it a considerable number of times, and can to a certain degree corroborate the statement made by Kortmann who says, "it seeks out the diseased tissue—as a dog does game—surely finds it, and effectually destroys it." but occasionally, perhaps, when the game is scarce, it appears to prey, in the writer's opinion, upon the margin of the healthy skin, and hence it requires some watching.

It may be used in various forms, and that of a paste, consisting of about equal quantities of the syrupy acid and kaolin, is the method most recommended. It is also painted on with a brush or injected hypodermically, 1 in 2) into the tissue in the diseased area. The simple method devised by the writer, and from which he has never seen any ill effects, is the following. After previous poulticing and ablation paint the ulcerated surface over with a 15 per cent Cocaine Solution several times before applying the acid, and wipe it quite dry with absorbent wool immediately before the acid is brought into contact with it. Make a little nap of the ulcerated surface so as to cut out neatly and accurately a folded piece of lint (2 plies) of the same size and shape as the

patch. These should be soaked for some minutes in the pure concentrated acid placed in a saucer, the surplus acid being removed by gentle pressure. The double layer of lint may be accurately applied to the diseased surface by means of dressing forceps.

The margins of healthy skin may be smeared over with any firm cerate to prevent the acid trickling over the face. The pain is often severe, and lasts some hours. The lint may be covered with oiled silk, but the writer does not do so. He applies some more acid to it with a brush after a few hours, without disturbing its position. It may be left in contact for about four hours. Authorities differ, some directing an application of 15 minutes, and others recommending one of 10 hours after which Spirit Lotion on lint may be applied under oiled silk. The number of applications required in any given case can only be determined by the effect. After three or four days the surface should be very minutely examined, and any suspicious portions subjected from time to time to the action of the acid, applied upon little circular islands of lint, for 6, 8, or 10 hours. The treatment will extend over several weeks or months, and as parts of the original patch become entirely healed, others, probably, may be discovered in which the diseased action is in full swing. Thus destruction and repair will be carried on at the same time in different regions of the same patch.

It will thus be seen that the management of true lupus by this method is most tedious, and makes severe demands upon the time and patience of the physician, but just as he begins to feel that he or the patient may be carried off by old age or some concurrent malady before the diseased patch has been all replaced by healthy, transparent, cicatricial tissue, he will probably be rewarded with a clean, smooth scar, showing no vestige of apple-jelly blossoms, and presenting the minimum of deformity.

Pyrogallie Acid is stated to possess some selective affinity for the new growth, and is applied in the form of an ointment (1 in 8), as a plaster (1 in 5), or brushed on as a saturated solution in ether, but its destructive powers are by no means so easily controlled as those of salicylic or lactic acids.

Arsenic, applied in the form of *Fowler's Solution*, is stated to cause the destruction of the new growth without injury to healthy skin. It should be applied daily till it causes severe inflammatory swelling, when its use is to be suspended for a time. Heller employs this method of dealing with both true and erythematous lupus, and speaks highly of the results. Arsenic in more concentrated form, is also used as a caustic as will be presently mentioned. Some specialists have reported very favourably of the injection of *Fowler's Solution* into the diseased region and its margins.

Hydroxylamine, a powerful reducing agent, has been successfully used as a local remedy in lupus, beginning with an alcoholic

solution (1 in 1,000) painted over the cleansed ulcers four times a day. Eichhoff increases the strength of the solution gradually and double or treble the above percentage is used, without producing secondary inflammation.

Caustics or corrosives are employed in the treatment of lupus with the view of causing the destruction of the diseased tissue in bulk. Nearly every known chemical substance capable of accomplishing the death of healthy tissue has been used for this purpose. From their use speedy and radical cure of the disease may be obtained, but the scars are often most unsightly. If too little depth of tissue be destroyed, the resulting useless irritation may hasten the growth of the new cell formation, and cause the roots of the disease to strike deeper into the soil. If too much or too great a depth of tissue be removed, the resulting scar will be proportionate. The only way in which these remedies can be safely used is by the specialist, who, confining himself to the employment of one or two members of the group, will soon acquire a thorough and complete mastery over the drug. It is surprising to see how satisfactory are the results obtained upon this principle by quacks who confine their attention and practice to the removal of epithelial and other cancers and lupus, though it must be remembered that pride and other motives tempt their patients to hide the failures.

Kaposi applies for 24 hours a paste composed of Chloride of Zinc and Butyr of Antimony in equal quantities, with haz as much strong Hydrochloric Acid, mixed with the same amount of Liquorice powder. The following are also used.
viz. —

Vienna Paste, made by mixing Caustic Potash with rather more than its own weight of water, and adding a little rectified spirit. London Paste made by mixing Caustic Soda with an equal weight of recently-burned lime, and adding a sufficient amount of rectified spirit.

Hebra's Paste of Arsenic, composed of—

R. *Acid Arsenos.* gr. xv.
 Hydrarg. Sulphid. Rub. gr. xlv.
 Unguent. Rosæ ℥vi. misce.

Fiat Unguentum M. d. u.

Iodine Paste or Cream is prepared by triturating equal quantities of Pure Metallic Iodine and Tincture of Iodine together, and adding to the mixture an equal amount of Glycerin.

Nitrate of Silver is still occasionally used. It was a favourite remedy of Hebra. It may be used as a solution (60 grs. to 1 oz. or as the solid stick, which is better. This may be thrust into the papular or tubercular elevations, and, though terribly painful, is

very efficacious when thoroughly and persistently applied. The pointed stick of Caustic may be thrust into each lupus nodule after puncturing it with a lancet.

Caustic Potash in stick is the basis of Veiel's plan. After anaesthesia this agent is used to plough up the entire patch; it is then dried with lint and dressed with a 10 per cent. Pyrogallol ointment as long as the patient can bear it, when the ointment is changed to $2\frac{1}{2}$ per cent. strength till healing results.

Acid Nitrate of Mercury is an excellent and manageable caustic which the writer has used with great satisfaction when the disease is very superficial and limited in extent. It may be applied daily upon cotton wool twisted round a probe.

Carbolic Acid, the solid acid liquefied by heat, may be applied every day after drying of the surface, its action is, however, very superficial, and in many cases it does not reach the diseased stratum at all. Pure Creosote is better. Both agents are powerful if applied after scarification.

Nitric Acid, in concentrated form, may be tried by means of a glass brush or wooden spatula, but it is open to the same objections as the last-mentioned agent.

Potassium Permanganate has been recently used with great success by Kaexanowski, who, after cleansing the patch by frequent sponging and soaping, dusts on the dry salt in one single application. It forms a scab which drops off in fourteen days, and the patch heals rapidly.

Chromic Acid has been recommended, but it is a treacherous caustic for the face. It may be used when the mucous membrane has become affected.

Iodide of Sulphur (1 dr to 1 oz.), in the form of ointment, is recommended, but it produces pain and inflammation out of proportion to the good which it does.

Ethylate of Sodium Solution is an excellent caustic where there is little tissue calling for destruction. The B.P. Solution may be daily brushed over the diseased patch (which should be dried with blotting-paper), by means of a glass brush till a scab forms, which falls off in a few days, after which the applications are to be renewed. If pain is severe, a drop of Chloroform may be applied. This converts the Ethylate into Ether and Chloride of Sodium. The scarring is comparatively slight. (See also under *Nævus*.)

Perchloride of Mercury has been used in various forms and in solutions of various strengths from the 2 grs. per ounce, which is rubbed on with the view of preventing the growth of the bacilli, to the 20 grs. per ounce solution in alcohol, which is employed with the view of destroying the tissue. Unna's method of using this agent as an auxiliary to treatment by surgical or salicylic processes, is a very important step in the problem of treating lupus. After dealing with the disease in bulk by the more radical measures, it is found that scattered nodules, about the margin of the sore

subcutaneous fatty layer, and the repair of the breach by a plastic operation. Skin-grafting has given good results in such cases. Excision is certainly the most satisfactory of all treatments when the lupus is not upon the face, but upon some covered part of the body.

LYMPHADENITIS.

In simple acute inflammation of lymphatic glands occurring in healthy individuals, the first indication is to treat the cause. As this in most instances will be found to be the absorption of some septic product originating in a wound or abrasion upon the distal side of the gland, the condition of the wound or focus of infection will require attention. This may often be traced to the absorption of septic matters from necrosing teeth and diseased tonsils. In this way most of the cases of inflamed glands about the angle of the jaw may be accounted for, and the constant entrance of tubercle, in the opinion of the writer, by these inlets calls for most rigid attention to the state of the gums and teeth.

The acutely inflamed gland wherever situated is to be covered with an antiseptic dressing under oiled silk, and as there is generally acute inflammation (lymphangitis) of the lymphatic vessels between the wound and the inflamed gland, the band or strip of skin should be painted over with the B.P. Liniment of Iodine, which often acts like a charm in reducing the lymphatic irritation. Rest to all the parts (muscles, joints, &c.) in the neighbourhood of the inflamed gland must be secured.

The constitutional treatment should be directed to the reduction of fever and relief of pain, a smart saline purgative followed by small doses of Aconite, and a milk or fever diet being administered. In septic cases, or those following poisoned wounds, a liberal nutritious diet, with alcoholic stimulants and concentrated beef extracts or soups, may be commenced as soon as the first acute symptoms have been combated. Basham's Mixture, or large doses of the Tincture of Iron, alternating with full doses of Quinine, afford the best internal treatment. Sulphocarbolates may be given with advantage.

Local treatment should consist in measures likely to relieve tension and check inflammatory action in the gland.

Cold and hot applications have each their advocates, and the same result—i.e., resolution without suppuration—may be secured by either. By ice, evaporating lotions, cold compresses, or Lester's tubes the tension and arterial supply are soon markedly lessened, and the inflammation as evidenced by pain, heat, redness, and swelling soon diminishes or disappears. When hot or warm compresses or poultices are applied, as shown by Brunton, the capillaries of the collateral circulation are dilated and the current is diverted from the inflamed vessels. Up to a certain point both methods of treatment tend to prevent suppuration, and the writer has satisfied himself that, contrary to the popular notion, warm

poultices prevent suppuration by reducing the tension of an inflamed gland if applied at an early stage the general relaxation of the tissues sometimes speedily relieving the tension which is fatal to the life of the organ. At a later stage, by keeping up a continuous moist warmth and making the part an internal one, poultices hasten the pointing of the abscess.

Nasiloff treats inflamed glands by using compresses at a very high temperature. He drops several plies of linen into boiling water, squeezes them out quickly, and applies them directly over the inflamed gland and envelops the part for 15 minutes in a thick pad of cotton wool. A large sponge squeezed out of very hot water and covered with mackintosh makes a good application.

The best guide to the selection of hot or cold applications is the sensation of comfort or pain produced, the application from which the patient derives the greatest ease being always preferred.

Spirit lotion (1 to 3) applied upon lint and covered with oiled silk is one of the best possible local applications. If gently warmed before coming into contact with the skin, and if a thick layer of cotton wool be lightly bandaged upon the top of the oiled silk, an antiseptic poultice of the highest merit is thus obtained.

It is doubtful if the various abortive treatments employed, with the view of cutting short the inflammation and preventing suppuration, are of much value, but several counter-irritants are recommended for this purpose. The writer has occasionally obtained satisfactory results from freely painting the skin over the inflamed gland with Iodized Phenol (1 oz. Iodine rubbed up with 4 oz. warm Carbolic Acid). Solid Nitrate of Silver is rubbed upon the previously moistened skin by some, others brush over a strong solution of it.

Iodine, Carbolic Acid, Collodion, Perchloride or Pernitrate of Mercury Solution, and other substances, are painted over the integument under which the infected gland lies. Blistering is also resorted to, but it is most objectionable in acute cases. Carbolic Acid has been injected a few minims into the inflamed gland with the view of preventing suppuration.

Rubbing in of liniments or friction in any form is almost certain to determine the formation of matter. The actual or Paquelin's cautery lightly passed over the skin occasionally appears to retard or prevent suppuration. (See also under Bubo and Boils.)

When pus has evidently formed in the gland its speedy evacuation should be accomplished. Aspiration is worse than useless, and the plan of making a punctured wound and squeezing out the matter is objectionable.

The old-fashioned free incision is the best, and unless there be much pain and increased tension a poultice had better not be applied. Warm spirit lotion under oiled silk is a comfortable antiseptic for small abscesses of this sort.

In the majority of instances the free incision does away with the necessity of a drainage tube. A small wound is of much advant-

age if the scar is visible, and where the adenitis follows some irritation about the jaws the incision should be as limited as possible, compatible with evacuation, and a fine drainage tube or a few shreds of carbolized tow or horse hair will establish the removal of all pus as it is secreted. (See page 13, where the aseptic treatment of acute abscesses is detailed.) After the free removal of pus and the application of spirit lotion under oiled silk, the cavity may be syringed out with weak Sublimate solution (1 in 3,000) from time to time as it heals up from the bottom.

In *chronic* cases it is equally necessary to find out and treat the primary focus of infection, after which the gland enlargement if pus has not formed already, may be subjected to mild counter-irritation or friction with a stimulating absorbent. The Linctus of Iodine is often of some service, but the writer uses the Lin. Pot. Iod. Cum Sapone. Belladonna Plaster or the Iodide of Lead Plaster may be applied over the tumour. Where the enlargement remains and suppuration does not take place, this latter result may be brought about by the injection of various irritants, when to allow the gland to remain in its enlarged condition would be to keep up an eyesore. Carbolic Acid, Iodine, Acetic Acid, Perchlorides of Iron and Mercury, &c., have been injected.

Treves in such cases thrusts the finest point of the thermocautery through the skin, and moves it about inside the gland in order to break up and cause disintegration of its tissue, after which he inserts a fine drainage tube and applies poultices.

The best treatment is to make a small incision with a fine abscess knife and pass in over its blade a slender spoon, and scrape out the entire contents through the narrow opening, wash out with a weak antiseptic, and dress with iodoform or sublimate gauze.

Where pus has already formed in chronically inflamed glands the best treatment is certainly to regard the gland as an ordinary chronic abscess requiring free incision and the total excision of its sac and contents as described under Abscess on page 15.

It must not be forgotten that the great majority of these chronic, suppurating, and cisterning glands are of tubercular origin, and they together with all the other lymphatic glands in their immediate vicinity, must be carefully dissected out and all sinuses slit up and scraped and permitted to heal from the bottom. The question of dealing with these will be more fully discussed under Scrofula.

Many years ago the writer successfully dissected out a mass of chronically enlarged glands below the groin, in the interior of which a large calcareous deposit had formed, and which had been supposed for years to be a case of disease of the upper end of the femur. A probe passed into any of the numerous sinuses always struck on what felt like diseased bone. Rapid healing, with trivial cicatrix, resulted.

LYMPHADENOMA.

The only treatment for a simple hypertrophy of solitary lymphatic glands is removal by the knife. Considering that there is good ground for believing that a solitary adenoma may be the starting point of the disease, known as Hodgkin's Disease, the early removal of the growth is strongly indicated. Even when several contiguous glands are markedly enlarged without any increase in the size of the lymphatic glands throughout the body and without splenic disease, and in the absence of considerable increase of white corpuscles in the blood, the operation should not be long delayed.

When the constitutional features of the mischief, known as non-leukemic lymphadenoma or Hodgkin's disease, have become established, extirpation of the tumours is much worse than useless. All that can be hoped in such cases is that by attention to health through improved feeding, change of residence to a healthy seaside resort, and the employment of every means by which digestion and appetite can be improved, that the disease may be retarded in its progress by the administration of special remedies.

Arsenic in very large doses has been found to cause disappearance of the glandular enlargements and restoration to health. Many observers have reported that marked improvement for a time has followed its use, and sometimes there is good ground for believing that the invariably fatal progress of the malady has been held in check for considerable periods by its steady administration. It may be given in combination with Iron, for although this drug appears to have no effect upon the anemia present in the fully established disease, it appears to materially increase the beneficial action of arsenic. Fowler's Solution should be commenced in doses of 5 minims and increased till 15 minims, three or four times a day, are administered immediately after food. Large doses have been given without producing any ill effects. The remedy has been injected with a fine needle into the enlarged glands but it is doubtful if this is of any use. Where it causes irritation in the stomach and bowels, the hypodermic method of injecting 5 minims diluted with one or two drachms of water into the areolar tissue may be resorted to.

Cacodylate of Soda should give better results than Fowler's Solution, since it is less irritating and may be given in large doses without danger. $\frac{1}{4}$ grain may be injected once daily without risk.

The other remedies believed to be of some use in this disease are Phosphorus, Iodide of Potassium, and Cod Liver Oil. Where Arsenic and Iron cannot be well tolerated or when they fail, Phosphorus may be tried in conjunction with Cod Liver Oil. The Phosphide of Zinc has been resorted to by Reclus and others with some apparent benefit, but as Arsenic had been generally previously employed in the cases reported it may have been the

cause of the temporary improvement. Mercury should not be given. Of local remedies or methods all have proved unsatisfactory. The excision of the glandular tumours and the injection of arsenic into them have been already referred to as unsatisfactory; the same may be said of galvano-puncture, the injection of Carbolic Acid, Iodine, Chromic Acid, and various other irritants.

The administration of Thyroid, Thymus, Spleen, Lymphatic Gland and other animal extracts, and feeding by Bone-marrow have not led to any very hopeful results.

LYMPHANGITIS OR ANGEIOLEUCITIS.

Where the chief trouble appears to be centred in the lymphatic vessels the same principles are to be recognised in the management of the case as have already been detailed in speaking of the treatment of inflamed lymphatic glands under Lymphadenitis. Attention should be at once directed to any injury or wound which has been the starting point of the affection. This should be treated by antiseptic poultices (Spirit or Carbolic Lotion, under oiled silk), and the free evacuation of any collections of pus by proper incisions. Where the lymphangitis is superficial, and the red, tender, painful, and swollen lymphatic vessels can be discerned extending from the wound in the direction of the lymphatic glands, the greatest good can be got by painting over the inflamed area with the Liniment of Iodine, and prescribing absolute rest to the affected limb. Heath strongly advises the application of a cream, consisting of equal parts of Extract of Belladonna and Glycerin.

In 6 or 8 hours an evaporating lotion or a warm spirit lotion may be applied. Where tension and pain are prominent, a large hot poultice may afford relief and even diminish the chance of suppuration. Pus should be evacuated as soon as it is found to be present, and antiseptic dressings applied warm.

Saline purgatives, Iron, Quinine, and stimulants, with pure air and wholesome plain food, such as milk and eggs in abundance, are all that are generally found needful.

MALARIA—See Intermittent Fever.

MALIGNANT PUSTULE OR WOOLSORTERS' DISEASE.

In the *external* form of anthrax, as soon as the nature of the local eschar justifies a decided diagnosis, active surgical treatment should be commenced without delay. This consists in the removal or destruction of the eschar or so-called pustule and the success of the procedure in preventing or minimising constitutional infection depends upon its early and prompt adoption. After excising the diseased tissue with a sharp scalpel, the galvano-cautery should be freely applied to the wound.

Where the pustule is very small, it may be treated as a carbuncle, by making a free crucial incision, and applying a strong caustic

like Potassa Fusa, Chloride of Zinc, strong Nitric Acid, or Pernitrate of Mercury. Some authorities inject Tincture of Iodine or strong Carbolic Acid into the centre of the eschar, and into the tissues around its base.

The complete excision by the knife and the after-application of the cautery should always be preferred when the constitutional symptoms have appeared. The wound may receive one or two dressings with a paste made by rubbing up Quinine with Spirit of Turpentine. This paste has been used by Rivas with success in several cases as a local method of dealing with the eschar without previous excision. The excision plan has been objected to as likely to lead to blood infection in the wound, and many cases have been successfully treated by injections of 15 minims of a 1 to 3 per cent. solution of Carbolic Acid into and around the pustule. Formalin, 1 in 1,000, has also been injected with success.

Where there is constitutional disturbance, showing that general inoculation has already occurred, or where the *internal* form of the disease is present without any eschar, the treatment must be as supporting as possible. Concentrated beef essences and highly nutritious soups or strong beef or mutton broth, and free stimulation, should be resorted to from the beginning. Quinine, Sulphocarbolates, Sulphites, Carbolic Acid Salicylates, and large doses of the Perchloride of Iron in combination with Mindererus Spirit, may be given. Muskett records 50 cases treated with Ipecacuanha, internally and locally without a death. Where pulmonary mischief has resulted from direct inhalation of the poison without eschars, the best chance will be given by surrounding the patient with an atmosphere saturated with Eucalyptus, Carbolic Acid, or Turpentine. The various complications, as pleuritic effusion, oedema of the glottis, hemorrhages, &c., must be dealt with upon ordinary therapeutic principles.

Selavo quite recently has again published the results of his extensive trials of Serumtherapy in the treatment of anthrax, and claims complete success by the injection of his Anthrax Antitoxin in the case of anthrax in the human subject and in domestic animals.

MAMMARY GLAND, Inflammation of.

Preventive treatment directed to the nipple by the application of Boric Acid or weak Mercurial solutions (see Nipple) during the later days of pregnancy and after delivery materially diminishes the chance of mastitis. Where the gland becomes swollen and painful, rest is the first indication. This is obtained by keeping the patient upon her back, with the breast supported by a sling or broad bandage passed under the dependent gland and over the opposite shoulder. The arm should be kept close to the side, but, as a rule, this can be managed by the patient without bandaging. The question of putting the infant to the swollen gland can only

be decided by experiment. It is better to give the nipple rest where the process of suckling is very painful, and indeed in any case where the breast-pump works satisfactorily and removes the accumulated secretion without pain, the child should be nursed by the sound breast from the beginning.

The decision to wean should not be too hastily arrived at as the case may, under judicious treatment, resolve, and the infant should not be deprived of its natural nourishment, but in this matter the judgment of the physician is of great importance, and, unfortunately, it is not a very rare event to witness an infant tugging at a breast, the seat of extensive suppuration, from the nipple of which pus may be sucked, with pain to the mother and perhaps fatal results to the child.

At the beginning of the mastitis, if coming under the physician's notice at this stage, the question of cold or hot applications has to be decided. As a rule, it may be said that cold applications are not well borne, and do not give satisfactory results, and then use should not be persisted in if a speedy diminution of the pain, heat, redness, and swelling does not occur. The best cold application is the ice-bag. Its use is often persisted in under the misapprehension that warm applications tend to determine suppuration, but, as already mentioned under Lymphadenitis and elsewhere, it has been pointed out that warm or hot applications, by relaxing the tissues and diminishing the pressure often relieve the tension, which is more or less fatal to the life or integrity of the part affected.

If, then, the ice-bag or cold evaporating lotions are not soon followed by relief of pain and diminution in the tension of the breast, they should be discarded for moist and warm or moderately hot applications. Of all the forms of applying moist warmth to an inflamed breast, the writer finds none so convenient and satisfactory as the following —

A shallow wooden bowl or basin, after the fashion of a small butter-dish, large enough to more than cover the swollen gland, is to be procured. After stuping the breast with hot flannel cloths, a soft sponge or soft flannel squeezed out of hot water is to be laid in the inside of the wooden basin, which is then inverted upon the breast. If the basin is of the proper size a most soothing and comfortable moist warmth can be obtained for hours. Several layers of lint soaked in warm Spirit Lotion (1 to 2) may be used instead, and covered in by a piece of oiled silk. In these ways all the advantages of a poultice, without many of its drawbacks, may be obtained.

A favourite application is Belladonna, and occasionally the physician may be rewarded by hearing that it gives some relief. The stereotyped formula of the Green Extract rubbed into a thin paste or cream with Glycerin is the one generally employed. It is, however, inconvenient and filthy, and very often fails. Where the therapeutic action of Belladonna is desired a little of the liniment (which is almost colourless) may be added to the warm

Spirit Lotion, care being taken that the child be not put to the breast.

The following formula may be used with advantage in many cases where the skin is unbroken. —

R. *Linnm. Belladonnae* ℥vj.
Linnm. Aconiti ℥ij
Spiritus Vini Rectificat. ℥iv.
Aquæ Rosæ ad ℥xii. *misce.*

Fiat applicatio *Signa*—"The lotion to be applied upon lint to the inflamed breast, and covered with oiled silk."

Such a warm moist application need not be changed oftener than every eight hours, if a large thick pad of warmed cotton wool be laid on over the oiled silk, and retained in position with a light broad bandage passed over the opposite shoulder. The extract with glycerin, smeared over the surface of a warm poultice, often affords relief.

Arnica, *Sal Ammoniac*, *Jaborandi*, *Digitalis*, *Chloral*, *Laudanum*, *Stramonium*, *Hemlock*, *Marshmallow*, *Tobacco*, *Hyoscyamus*, and many other substances have been used, but, as a rule, moist warmth accomplishes everything, and much more than these do. The use of *arnica* is to be condemned always. Where a poultice is employed, the writer has found great satisfaction in smearing over its surface with the Ointment of Conium. This often gives better results than belladonna. Another valuable agent is Ichthyol 10 per cent. ointment.

Whilst local measures are being used much may be done to allay the constitutional disturbance with minute doses of *Aconite* or *Tartar Emetic*, combined with a diuretic, but the chief indication is to check for a time the abundant supply of milk. This is best accomplished by a diet in which there is as little liquid element as is compatible with the patient's comfort, and at the same time the bowels should be frequently purged by the administration of small doses of saline cathartics, the best of which for this purpose is tea-spoonful doses of Sulphate of Magnesia, or table spoonful doses of Rochelle Salt dissolved in lemonade. One large dose of Iodide of Potassium (30 grs.) sometimes stops the secretion effectually and recently the painting over of the swollen gland with a 5 per cent. solution of Cocaine has been found successful.

At this stage nurses are very fond of friction or massage upon their own account, and every physician can recall cases where mammary abscess has been the direct result of unwise manipulation of the gland. Nevertheless, friction judiciously and skilfully applied will be found to be a powerful remedy for good, especially in those cases where the breast-pump or infant causes much pain to

the fissured or ulcerated nipple. Friction when roughly applied is very liable to determine suppuration and, consequently the physician should at first carry out its application himself. It should be gentle and almost painless, and the pressure should be commenced at the periphery or circumference of the breast, and should be applied in lines converging towards the nipple and a little oil or camphor liniment may be smeared over the skin before commencing the operation.

In this way a very painful and engorged breast following upon, and directly caused by, a fissured nipple may be relieved of the tension resulting from retained secretion, and thus the danger of suppuration may be avoided—but where gentle friction, applied in lines from the circumference to the centre, causes severe pain without relieving the tension of the breast, its continuance should not be advised. The other measures recommended should then be resorted to again—viz., moist warmth, gentle pressure by a bandage, regulation of the diet, and free purgation. Iodide of Potassium in large doses with Belladonna internally and a little Morphia will diminish the secretion.

Excellent results have been obtained without poultices or warm fomentations, simply by the application of *elastic pressure* and this when it succeeds in giving relief as soon as it is applied, may be used as the only local treatment. Where there is much pain and tenderness Horne applies a 5 per cent. Oleate of Mercury and Morphia Solution, over which is placed a thick layer of cotton wool enveloping the entire breast. Upon the top of the wool an elastic woven or pure rubber bandage may be so applied as to exercise a comfortable elastic pressure, by passing it round the chest and over the opposite shoulder till the inflamed gland is evenly covered. One great advantage which this method possesses over all others lies in the fact that the patient may freely move about without interfering with the rest of the inflamed organ. Verneuil employs compression by means of light perforated corsets lacing behind, and the pressure is equalised by pads of wool placed over the gland. The child can drink at the sound breast till the inflammatory action subsides in the affected one, after which it may be able to take its share in the work of nursing. Galvanism has been tried, but the results are unsatisfactory. Boissard treats all cases of galactophoritis (inflammation of the ducts by chlostriforming the patient and applying strong pressure till every drop of pus is squeezed out through the nipple, he then sprays with Sublimate or Naphthol solution, applies a compress, and repeats the operation three or four times, and has success always within a week.

No treatment will be based upon truly scientific principles which omits to deal with the almost invariable cause of the mastitis—i.e., ulceration abrasion, or fissure of the nipple. There is little doubt but various germs gain admission to the ducts in this way.

When notwithstanding the employment of these various remedies

it becomes evident that pus has formed, either upon the surface of the gland, in its substance, or in the areolar tissue behind it, its early evacuation by a free incision will be the first thing that will give relief. It is always wiser, when circumstances permit, to make the incision under an anæsthetic. The breast is exquisitely tender, and without anæsthesia it is rarely possible to make an opening so free as is desirable, and especially to open up all pouches and secure perfect drainage. Nothing but harm can result from the mere puncture, which is so often made; the operator obtains a few drops of pus, and consoles himself with the belief that the rest will follow. When, however, there is no sign of pointing hot poultices or very warm fomentations may be continued till the matter shows some signs of the route by which it intends it reach the surface, after which an incision should be made at the most dependent part to ensure thorough drainage, and, if considered necessary, a small drainage tube may be inserted under antiseptic conditions, and the abscess cavity may be occasionally syringed with weak Carbolic, Corrosive Sublimate, or Boracic Acid solution. In making the incision it is advisable to keep clear of the nipple lest it should become involved in the cicatrix, and by suffering retraction, afford a barrier to future use; and the knife should be directed in the course of the milk ducts—i.e., from the centre in a direction towards the circumference. Rarely will a counter-opening be necessary.

In submammary abscesses the incision should be made along the lower border of the gland which need not be included in the wound, and a large drainage tube should be inserted.

Where more than one abscess cavity exists in the gland tissue, a free incision, under antiseptic precautions, should be made, and the forefinger introduced and used to break down the intervening dissepiments of inflamed glandular substance or independent openings may be made, drainage tubes introduced, and antiseptic dressings and pads of carbolic or iodoform gauze applied. Upon the first change of the dressings, which need not occur under ordinary circumstances for three or four days, often remarkable progress in the healing process may be noticed.

The application of moist warmth by poultices and fomentations should cease upon the arrival at a decision to incise, and the strictest antiseptic precautions should be rigorously insisted upon afterwards. Often the child need not be weaned, though the constitutional disturbance will sometimes solve the problem by checking the milk supply in both breasts, but the persistent use of a good breast-pump may keep the sound breast secreting till the abscess is put upon the road to recovery, when suckling may be again permitted.

Although one often sees in the case of poor women that a child continues to thrive who has all along been kept even at the inflamed or suppurating breast, nevertheless it is advisable to reject the milk pumped out of the breasts till the severity of the constitutional

symptoms passes off. Sometimes weaning must be carried on where the sucking of the child at the sound nipple causes such a rush of blood and rapid secretion of milk in the inflamed breast as seriously retard or prevent resolution.

Where sinuses remain long after the active mischief has subsided, they, and the cavities to which they lead, should be slit up and scraped by a Volkmann's spoon, and touched with a strong solution of Chloride of Zinc and dressed antiseptically.

When considerable hardness and induration remain, the breast may be strapped with Mercurial Plaster, or after rubbing in a weak Mercurial Ointment or a solution of the Oleate of the same metal. A Belladonna Plaster may be worn, or the rubber bandage may be tried for a short time. Iodides internally, in full doses, may be given with advantage in such cases.

The writer has seen a case where a series of chronic abscesses continued to form for nearly a year, and though sinuses were freely slit up and scraped and rapid healing resulted, other abscesses or sinuses appeared afterwards, and only yielded to the slitting up and dissection of every tract where pus had formed. Such cases are wearisome, and can only be successfully treated by radical measures. The injection of anti-septic liquids, counter-irritation, strapping, pressure and the administration of internal remedies are worse than useless, as they may only tend to keep up the irritation.

Galactoceles or milk cysts, when they form, should be freely opened with proper antiseptic precautions, a portion of the cyst wall excised, and the case treated upon general surgical principles. Very good results have been obtained in these cases by compression.

MANIA.

As mentioned under Insanity, the treatment of the different forms of mental disease can only be carried out in special institutions possessing the numerous requirements which are now considered necessary for the successful management of the insane. This remark applies to ordinary acute mania, but it will be necessary to briefly refer to the management of acute delirious mania (sometimes called brain fever), a serious and often fatal disease coming on with surprising suddenness, and requiring treatment before the necessary removal to an appropriate asylum can be determined upon or carried out.

The first point in the management of such cases is to look closely to the feeding and as the patient almost always refuses food, forced feeding should be commenced without delay, and steadily insisted upon in spite of all obstacles every third or fourth hour during the day and night.

Strong broths, beef essences, milk and eggs, and a small quantity of stimulant in most instances should be introduced into the stomach by means of the India-rubber tube. Nutrient enemata should be also given. At a later period Cod Liver Oil should be given in ounce doses when the stomach retains it.

In addition to these supporting measures, sleep and quiet must be secured, and Sulphonal, Trional, Paraldehyde, Bromide of Potassium, Hyosine, or Duboisine is called for. Hydrobromide of Hyosine subcutaneously in doses of $\frac{1}{160}$ gr. every hour for three doses is relied upon by Savage in severe cases. Opium is to be avoided, unless other hypnotics fail. Chloral is the favourite drug, and with many specialists the treatment of this affection is summed up in the words "feeding and chloral." Peterson advocates the use of the hot wet pack as the best sedative in this condition, and the patient, who often falls asleep, may be kept in it for hours. It may be applied as described under Bright's Disease. (See under Insomnia, where the relative merits of all the hypnotic and narcotic drugs are fully discussed.)

MASTOID CELLS, Suppuration of—See Ear, Diseases of.
MASTURBATION.

The evils arising from this degrading habit have been generally exaggerated, and as regards treatment, the physician will be much more frequently consulted by hypochondriacs who imagine that they have been injured by the practice than by those who continue to pollute themselves by it. With children the case is different. Detected by their parents or guardians, the advice of the physician is often sought as to the best method of putting an end to the habit, and if there be any causes such as adherent prepuce or phimosis, or a very long foreskin, circumcision generally effects a speedy and permanent cure.

In the case of lads about puberty, who have discovered or who have been taught the evil habit by others, circumcision may also be resorted to, as an elongated prepuce is a constant source of suggestive irritation, and, when present, appears to greatly aggravate the vice. Moreover, the operation certainly makes a distinct break in the habit, which, with close supervision and good moral treatment, may end in a complete emancipation from the thralldom which some boys have not the force of character to break through without external assistance.

In the case of girls any unhealthy condition of the genital organs may lead to the establishment of the habit, and absolute cleanliness, with close supervision, may lead to a removal of the trouble. With older girls, who have been educated by others into the practice, only moral treatment will be of use. These cases are most unsatisfactory, as too often masturbation gets hold of those in whom the moral sense is not very acutely developed, and there may be little to appeal to.

It is often a symptom of mental deficiency or the first indication of some psychological disturbance, and has too often been regarded even by specialists as the *cause* instead of the *result* of insanity.

Where moral treatment fails, resort to mechanical methods of preventing the act may be tried by tying the hands after undressing at bed-time, and by arranging that the patient shall not

sleep alone, or by causing the patient to sleep with a hard body like an empty cotton reel fastened over the spine, so that when he turns upon his back during sleep its pressure awakes him. The plan of blistering the penis or labia is a severe and almost brutal method, open to serious objection, and not even likely to be followed by any permanent benefit.

Free purgation, or measures to ensure the regular emptying of the rectum and the removal of thread worms or anal irritations from whatever cause, are not to be overlooked.

The avoidance of bad companions and indulgence in filthy conversation and impure literature must not be omitted. Free open-air exercise, pushed to the extent of inducing fatigue before bed-time, plain, unstimulating food, change of scene, of amusements, and of surroundings, and attention to every measure calculated to improve the physical tone, should be advised.

Where moral treatment fails entirely, drugs are not to be depended upon, but where there is a continual struggle between an unhealthy, precocious, sexual appetite, and a weakened will, victory may be won for the latter occasionally by the administration of Bromide of Sodium or Potassium, in conjunction with Iodide of Potassium and cold baths.

Blistering over the occiput and upper cervical spines is occasionally useful in allaying the excitability of the sexual centres.

The physician is often consulted by perfectly healthy patients who have practised the habit of masturbation for a time during boyhood, and who become almost distracted, after the perusal of some sample of pernicious quack literature, with the thought that they have ruined themselves. In such cases, the firm assurance of the physician that the habit has left no injury behind it generally restores the patient's mind to a healthy state. (See under Impotence, Spermatorrhoea, &c.)

Regarding preventive treatment, it is a serious question whether boys should be warned against the evils of a practice of which they may know nothing, and there cannot be a doubt but that in some few cases such warning may produce the opposite effect though many authorities who have had considerable experience of the training of boys follow the practice of sounding an alarm as a matter of routine. To be free from objections such warning must be most judiciously administered to innocent and sensitive youths.

For the prevention of masturbation in insanity, Clarke has successfully performed neurectomy, removing half an inch of each of the nerves on the dorsum of the penis through a transverse incision half an inch from the root of the organ.

MEASLES.

The treatment of all the exanthemata differs little except in points of detail, and the following remarks will apply also to the

general management of scarlatina, typhus, typhoid, and smallpox. At the onset of the disease (which can now be diagnosed by the presence of Filatow's spots on the buccal mucous membrane at least one day before the eruption appears), the patient should be put to bed. A wire spring-mattress, upon the top of which a thin, hard hair-mattress is placed, and a moderate amount of bed-clothes, should be provided. The temperature of the sick room should not be allowed to exceed 60° F. Certainly, in the absence of special reasons, such as laryngeal complications, the atmospheric temperature should not exceed 65° F., or at the highest 70° F. Thorough ventilation should be secured, and a continuous supply of pure warm air is essential. In measles it will generally be found necessary to have some arrangements for moistening the air, the ordinary bronchitis kettle answers all requirements. Tate's Thermic Ventilator is a most valuable sick-room luxury. Where the physician has the choice of rooms for the treatment of any of the exanthemata, he should select a large, airy apartment, with an open grate, and, when possible, with a ventilator opening into a flue. The bed can be surrounded by a couple of screens in a large room; this will enable the most thorough ventilation to be carried out without subjecting the patient to draughts of cold air. It is very desirable to have two beds in the sick room, one for the day and the other for the night, and, when possible, it is an even better plan to have one bed for the night in an adjoining room which communicates directly by a door with the day room.

In the case of measles, it is customary to have the light subdued by partially drawing the blinds, but the complete darkness so often insisted upon is unnecessary, and the patient's own feelings may be taken as a guide in this matter. The less unnecessary furniture and hangings or drapery the better.

In the management of scarlatina and smallpox this is of considerable importance, and it is well to clear everything out of the room that cannot be afterwards subjected to thorough fumigation or disinfection. The physician should give such instructions regarding the use of disinfectants during the illness as will prevent the risk of injury to the patient by their being employed too freely.

In treating infectious diseases in the patient's home, it is a good plan to place a large vessel filled with water and Condy's Fluid (about 1 in 50) outside the door of the sick-room. Into this vessel all articles leaving the room may be dipped. In the case of scarlatina and smallpox, a sheet dipped occasionally in a solution of Carbolic Acid (1 in 100) or Chlorinated Lime (1 in 200) may be suspended outside the door, in order to more effectually cut off the room from the other parts of the house. Urine and feces should be passed into vessels containing a small quantity of some disinfecting or deodorising substance. Terebene, Eucalyptus, Carbolic Acid, or other spray may be diffused through the atmosphere occasionally.

In the early stages of the fever of measles very few drugs are required. The following old-fashioned mixture can do no harm, and often affords some relief by encouraging the action of the skin; it may be administered till the decline of the eruption. —

R. *Spiritus Æther. Nitrosi* ℥ii.
 Liquor. Ammon. Acetal. ℥ii.
 Syrupi Croci ℥i.
 Aqua Destillata ad ℥iv. msc.

Fiat mistura. "A tea-spoonful of this may be given every two or three hours to a child from 2 to 4 years of age."

Diet must be closely attended to. Where the patient can take milk freely there is no difficulty, as milk alone or diluted with half its amount of Lime water, or Aerated Soda or Kah water may be given in any quantity. Where the patient has a natural dislike to milk, weak soups, beef tea, or any liquid nourishment may be given. It is, however, a mistake to force nourishment under these circumstances. Often a child who refuses milk can be tempted to take tea, and this may consist chiefly of milk flavoured with a little tea. In such a liquid, biscuit may be soaked, or toast and crumb of bread may be added.

As the fever increases diluent drinks may be freely given, and it is wrong to refuse cold water when the patient craves for it. It is difficult to see the origin of the popular prejudice against water being allowed to patients parched with fever. It should only be temporarily withheld in those instances where it is taking the place of nourishment. Weak barley water, to which lemon juice and a little sugar have been added, or home-made lemonade may be freely given. When thirst is very great, ice may be freely administered in small quantities.

Fever when running very high must be checked, and, as there is a strong objection to the cold bath as an antipyretic before the appearance of the eruption, the temperature should be watched, and when it reaches above 104° an antipyretic should be administered.

Quinine is the safest and best of these, and may be given in doses of about $\frac{1}{2}$ gr. for each year of the child's life *ter in die*. In severe cases double this amount may be given for two or three doses.

Antipyrine or Antifebrin may be safely given in measles under such circumstances, though their routine administration in all cases of the disease is unnecessary. One grain of antipyrine or $\frac{1}{2}$ grain of antifebrin may be given every three hours to a child from one to two years old. When hyperpyrexia occurs after the rash has come well out, and where the temperature reaches 106° or more, a tepid bath or cold pack should be at once given, and the patient kept in it till the temperature falls to normal. With a

good nurse, sponging of the body in detachments answers most requirements, and the water at first may be tepid and afterwards cooled down. The bowels should receive one moderately smart clearing out by a saline purgative, and further purgation is unnecessary unless constipation set in. Diarrhea, if present, should not be interfered with unless it threaten to exhaust the patient's strength.

Coryza may be safely let alone. It rapidly subsides upon the decline of the eruption, and is generally relieved by cutting off the supply of bright light.

Cough is often most troublesome, and in some cases almost alarming and is liable to resist drugs till the eruption begins to fade. The diffusion of steam through the air or an inhalation of Conium or a very weak Carbohc Spray to the fauces, and Ipecacuanha Wine internally and warm poultices externally, generally afford relief. In adult patients Tatar Emetic (20 minims of the wine, with 5 or 10 minims of Liquor Morphie) may be given with advantage.

Itching, when the eruption is well out, may be a troublesome symptom. It is generally relieved by sponging the limbs and face with a warm or tepid solution of Bicarbonate of Soda, and by anointing the skin with weak Carbohc Oil.

Where convulsions occur, or where stupor with marked exhaustion is observed before the appearance of the eruption over the entire body, especially when traces of it have been observable for one or two days about the head, a *hot* bath should be given, with the view of causing a smart determination of blood to the cutaneous surface and when in the bath cold affusion to the head is very valuable. After such a bath the body should be properly rubbed dry with warm towels, and the patient wrapped up in flannels and put to bed before the possibility of a chill occurs.

Convulsions at a later stage generally indicate the onset of some serious complication, such as pneumonia or meningitis, which is to be met by the administration of such remedies as are indicated in these affections. Pneumonia is apt to run a very protracted course, and must be met by Ammonia, Quinine, Stimulants, and hot Poulticing.

Bronchitis, catarrh of the meatus or troubles in the middle or internal ear, ophthalmia, adenitis and other complications, are to be met by the remedies mentioned under the names of these affections, and since the microbes which cause many of the complications of measles are always to be found in the mouth, Dawson Williams points out the necessity of disinfecting mouth-washes and sprays. These latter are of great value in preventing otitis and they may be supplemented by careful syringing or washing out of the naso-pharynx immediately after which gentle Politzerisation may be occasionally carried out. He also points out that the broncho-pneumonia is communicable, and that a child suffering from it should not be nursed in the same room.

with others. (The writer has long since satisfied himself that this is undoubtedly true also of the pneumonia of "grippe".)

Stimulants are seldom necessary in ordinary uncomplicated cases, but where serious complications as those just mentioned are present they must be judiciously administered. The exhaustion and serious drain made upon the system by a severe attack of measles often lead to a fatal issue, notwithstanding the popular notion that the disease is generally a trivial ailment.

Hence, after the decline of the eruption, every care must be taken to keep up the general strength by large quantities of easily-digested and easily-assimilated food. The after-treatment is sometimes of much greater importance than the management of the case prior to the decline of the fever. Tonics may be needed to improve the appetite, and Iron to combat the anemia which often results. These objects may be accomplished at the same time by giving a mixture containing Quinine, with small doses of the Tincture of Iron. Cod Liver Oil is very valuable at a later stage. Where convalescence is protracted, stimulants may be employed in the after-treatment with advantage, and when administered they should be given with the food. Thus brandy or whiskey may be added to the milk. The writer prefers to give the stimulant in the form of wine whey, which can be readily prepared by adding one wine-glassful of sherry to one pint of milk, raised almost to the boiling point; the fine curd should be rejected. Children, as a rule, take this mixture readily. When whooping-cough is present, a not uncommon complication, the case calls for very careful management, free stimulation being sometimes essential, and further pulmonary troubles must be met by smart counter-irritation and expectorants. Serumtherapy will probably prove valuable.

Bichloride and Iodide of Mercury have been used internally as routine remedies, but the writer has no experience of their use. The Solution of Peroxide of Hydrogen has given good results.

In the absence of complications, the patient may generally be permitted to leave his bed, though still to remain in his room, after the lapse of a week. It is difficult to keep those who have just passed through a mild attack of measles from exposing themselves to the variations of temperature out-doors. The children of the poorer class run about often before the eruption has entirely faded, and the result is that numbers of them perish from secondary bronchial or pneumonic troubles. The dangers of exposure should be insisted upon to parents, and the body should be well enveloped in flannels, even in the summer time. In winter, a child should not be permitted to take open-air exercise for at least a month after the seizure. Drives should not be permitted till the patient has been allowed to move about. To all who have had much experience in the extern department of a children's hospital, it is evident how numerous are the cases of phthisis and severe visceral and bone affections, whose origin can be traced to the shattered

state of health following severe attacks of measles. In the writer's experience, which is not limited in this matter, such serious sequelae are much more common after measles than any other affection, and they point to the necessity for prolonged careful feeding and nursing, long after the period when danger is generally supposed to have passed over.

MEGRIM, MIGRAINE, or HEMICRANIA.

The treatment resolves itself into the management of the attacks, and also into the employment of such measures as will tend to prevent their recurrence.

Of the agents used to relieve the pain of megrim, none can be compared in certainty or rapidity of action to Antipyrine or Antifebrin. Though there is no doubting their efficacy, nevertheless, it is difficult to explain their *modus operandi*. Patients, who for years have been periodically laid aside, unable for shorter or longer periods to discharge the duties or enjoy the pleasures of life, notwithstanding the use of the older narcotics, have been now placed in the position thanks to antipyrine, that they need not suffer pain or inconvenience for many hours.

As soon as the patient feels the first symptoms of an approaching attack, he should be directed to take 10 grs. of Antipyrine, or 5 or 6 grains of Antifebrin in the form of a powder, mixture, or tablet. Should the pain continue, half these quantities may be given every hour for three or four times, but it is rare for an attack to stand out against the third dose. Where there is any reason to suspect that the drug may disagree or produce unpleasant symptoms, half the above doses may be given every 30 minutes. There is evidence that patients suffering from high fever can take much larger doses of antipyrine than if the temperature was normal. And though the writer only once saw any unpleasant effects from the drug in some thousands of administrations in numerous diseases, many instances of untoward results have been published from time to time, and it may be, upon the whole, wiser to give smaller doses, say 3 or 4 grains every twenty or thirty minutes, till relief follows. Unfortunately larger doses are required in subsequent attacks, and many patients affirm that these drugs lose their analgesic properties by repeated administration. This may be partially remedied by changing from one to another, or by giving the following in routine alternately, viz., Antipyrine, Phenacetin, Exalgin, Antifebrin, &c.

The writer has obtained the best of results by combining caffeine with antipyrine. It would seem as if the citrate prevents any unpleasant cardiac effects. Quinine may be added sometimes with advantage, thus—

R. Phenazoni gr. x.
Caffeina Cit. gr. iv.
Quinina Hydrobrom. gr. iv. misce.

Fiat pulvis, statim sumend. et repet. secundis horis.

Salicylate of Sodium is a favourite drug with many, and Little, who first advocated its use in megrim, gave 20 grs. in effervescent Citrate of Caffeine, and repeated it in two hours. It is valuable where the exciting cause is uric acid in the blood.

Haig has closely studied the relations existing between the paroxysms of megrim and the excretion of large amounts of uric acid, and found that by the administration of full doses of uric acid he could at pleasure check the amount of uric acid in the blood and in the urine. He gave 60 minims of diluted Nitro-Hydrochloric Acid in a tumblerful of water, one half of which was swallowed as soon as the pain came on, and the other half in 30 minutes later. The headache was generally removed in about an hour after the second dose. An equivalent of Citric Acid does equally well. The writer has not been able to corroborate this observation in a few cases in which he has tried the acid treatment.

Indian Hemp is a drug which has been found of considerable value in megrim, and the reports of Anstie, Seguin, Greene and others show that it not only relieves, but that it has been found to decidedly cure the disease, as the bromides sometimes do in epilepsy, $\frac{1}{4}$ grain of the B. P. alcoholic extract being given night and morning for 8 or 12 weeks. One statement made by Greene is at variance with the writer's experience. He states, "That unlike opium no craving for further doses follows its medicinal use, and apparently it can be given up without the slightest effort at any time." In severe cases it can be given with advantage after antipyrine has been employed to relieve the pain. It is also said to be a remedy of great value in *continuous headache*, especially when occurring in women. The drug is most variable in composition, and has generally disappointed the writer.

Bromides are sometimes of use in 30 grain doses in relieving the paroxysms, but they more frequently fail, and in the typical form of the disease they appear to have no appreciable effect in preventing the attacks, but where the attacks become almost continuous, i.e., in the so-called "status hemicranialis" bromides are of great use. They may in some cases be advantageously combined with antipyrine. Thus:—

R. Phenazoni ʒij.
Potassi Bromidi ʒiv.
Caffeinae Citratis ʒss.
Spiritus Chloroformi ʒij
Aque Camphorae ad ʒviii. misce.

Fiat mustura. Signa—"A large table-spoonful for a dose when the attack of headache comes on, and a dessert-spoonful every morning and evening between the attacks."

Caffeine and strong Coffee occasionally give some relief, and may still be employed in conjunction with antipyrine and cannabis.

Guarana, or an extract prepared from the ground seeds of *Paullinia Sorbilis* which contain the alkaloid guaranine, is more efficacious than caffeine, with which it is identical. Five grains of the alkaloid, or 25 or 30 grs. of the cake, may be given every two or three hours. It was, perhaps, the best routine treatment prior to the introduction of the antipyrine treatment, but it very frequently failed entirely.

Chloral Hydrate, by inducing sleep, may sometimes be found to cut short the attack. Butyl-Chloral Hydrate is of feeble power in megrim, and in the absence of neuralgia of the fifth nerve is not worth a trial.

Nitrite of Amyl or Nitroglycerin may be tried in migrainous headache, but in the typical form it rarely gives relief.

Menthol, Cajuput and Eucalyptus Oils have been given in doses of 5 to 10 grains or minims with very variable success.

Morphine hypodermically has been recommended, but its use is very objectionable owing to the after ill-effects in migraine, and to the danger of establishing the opium habit. In very violent cases it may be resorted to, and even Chloroform vapour has been recommended. Tonga, Belladonna, Pterate of Ammonia, Ergot, Gelsenium, Aetæa, Pterotoxin, Digitalis, Camphor Ammonium Chloride, Alcohol in one full dose, Henbane, Valerian, Sumbul, and many other drugs vaunted as cures from time to time, have generally proved valueless.

Locally, some agents may be useful at times in conjunction with the treatment already detailed. Amongst these may be mentioned warmth to the head, the ice-bag, Ether spray or Methylene spray, sinapisms to the back of the neck, tight bandaging of the head, or pressure over the temporal arteries, and exclusion of light, Atropine in the eyes, Belladonna to the forehead, and Menthol or Veratrine in the form of ointment over the brows.

Galvanism is of undoubted value, especially in the continuous migrainous headaches, and the writer has found it of much benefit to those who suffer from more or less constant headache between the attacks of megrim. The current from 4 or 5 Léclanché elements may be passed through the head for 2 or 3 minutes at a time, one pole resting upon the forehead, and the other below the occiput.

Purgatives are generally useless, and the darkened room is not indicated when we have drugs capable of giving speedy and complete relief.

Of the treatment between the attacks little can be said till their cause has been discovered, and in some instances a brilliant effect may be produced by correcting the fault to which they owe their origin. Thus, if the megrim has been depending upon some errors of accommodation or upon astigmatism, the paroxysms may waxes

return after these have been corrected by suitable glasses. Severe mental work, as a rule, does not produce megrim, but mental worry is a very common cause. Vexations of one kind or another, and irregularity in the hours of sleep, and prolonged anxiety or grief, are common factors. When such can be avoided, as by change of scene and occupation, marked relief follows. There cannot be a doubt about the great value of open-air life in migraine, and in many sedentary patients a lasting cure may be accomplished by a complete change of environment combined with open-air occupation without any drugs.

Though much has been written about the effect of tonics, the virtues of Strychnine, Iron, Cod Liver Oil, purgatives, special dieting, &c., little dependence need be placed in any of them only in as far as they bring a debilitated organism up to a healthy standard, after which, constant open-air exercise at every available opportunity, regularly in the hours of meals, time of rest, and in the periods of intellectual labour, will do much to prevent return. Constipation, insomnia, indigestion, lithæmia, &c., must be relieved and in the case of children, the shortening of school hours and the abolition of the pernicious cramming plans, the indirect outcome of the objectionable "result fees" system, may achieve a good deal.

Of the various specific drugs, which have been found beneficial in the prevention of megrim there is much difference of opinion about their relative values. The writer finds a long course of Arsenic in small doses the best. To this may be added a pill of the Extract of Indian Hemp, as already mentioned. $\frac{1}{2}$ grain may be given at bed-time. Chloride of Ammonium, Iodide of Potassium, Phosphorus, and Salicylates, with Alkalies, may be tried where arsenic fails. No harm can result from a nightly dose of the Bromide of Sodium or Potassium in conjunction with as much Cascara Sagrada as will keep the bowels open without purging.

Little advises sponging with hot water in the morning, followed by a cold douche over the shoulders and spine, and a sparing use of tea, with the following pill to be taken after breakfast and dinner:—

R. *Sodii Arseniatis* gr. $\frac{1}{2}$.
 Extracti Cannab. Ind. gr. $\frac{1}{2}$.
 Extracti Belladonnae gr. $\frac{1}{2}$.
 Zinci Valerianatis gr. ii. *misce.*

Fiat pilula. Mille tales xxiv. F. a. o.

Whitehead states that for the last 25 years he has never failed to treat successfully the most inveterate and severe cases of migraine by the introduction of an ordinary tape seton through the skin at the back of the neck. Some of the cases exceeded in

intensity any that he had ever known recorded. He inserts a piece of ordinary household tape, half an inch in width and about 9 inches in length through an incision (transfixion) made by a scalpel into the pinched up skin, 4 inches of the tape are left free at each side, and the patient moves the tape a little each day, the ends being always kept tied together. The seton is to be worn uninterruptedly for 3 months.

MELÆNA.

As this symptom depends upon the outpouring of blood into the stomach, small intestines, or the upper part of the large intestine, its treatment will depend upon the cause of the hæmorrhage. Thus an ulcer of the stomach, congestion of the liver, or ulcers in the duodenum or intestinal tube high up, may be the origin of the blackened or tar-like evacuations, and the appropriate treatment will consist in the judicious administration of remedies calculated to check the original diseases. Under Hæmatæmesis will be found the remedial agents used to stop the bleeding when its seat is in the stomach.

Most of these drugs are administered when the bleeding is from a point lower down in the alimentary canal. Acetate of Lead and Opium, Alum in large doses, and the Extract of Hæmatoxylon in pillular form, and Turpentine in the form of capsule, are employed to reach the bleeding surface in the small intestine. For the most part these agents are valueless, and the only reliable method of treatment lies in a rapid saturation of the blood by Chloride of Calcium (20 grs. every 4 hours), with the view of causing a high degree of coagulability. The Suprarenal Extract (3-15 grs.) may be used with the same intention.

MELANOHOLIA—See *Insanity and Hypochondriasis*.

MENIÈRE'S DISEASE—See page 252, and see under *Tinnitus*.

MENINGITIS, Cerebral (Simple).

The treatment of the original condition is of importance when the meningeal inflammation is found to be secondary to erysipelas, or disease of the petrous portion of the temporal bone, or when it occurs in the exanthemata, in pneumonia, syphilis, ulcerative endocarditis, and injuries to the cranial bones.

The patient should be put to bed and kept upon his back, with his head elevated. The utmost mental quiet and absence of noise, bright light, and jarring vibrations of every sort, must be ensured.

Diet should consist of small quantities of iced milk, and in the earlier stages animal food, even in the form of beef tea or meat extracts, should not be administered, and the same remark applies to alcoholic stimulants. One smart purge should be given to

ensure the thorough evacuation of the intestinal contents. A moderate dose of Calomel, followed in 5 or 6 hours by a saline cathartic, is a good routine method of accomplishing this object.

Where pain is a very prominent symptom, two or three leeches may be applied to each temple or behind the ears.

Cold to the scalp is the most valuable local treatment, and in order to ensure its application to the best advantage the hair should be cut close by sharp scissors, or, better still, the head should be thoroughly shaved. A light rubber ice-cap or bag, or a bladder moderately filled with small pieces of ice, should be applied evenly to the forehead and scalp. Where this is not at hand, a good substitute may be quickly extemporised by tying up a quantity of broken ice in a sheet of thin gutta-percha tissue and applying it in the same way. Cold lotions or compresses of lint or linen containing small pieces of ice in their folds, may also be used. Letter's tubes are sometimes preferred. A handkerchief wrung out of iced water, and frequently renewed, answers well in the case of restless children. The persistent use of cold applications to the head always affords some relief, and may induce sleep after other methods fail.

Counter-irritation to the nape of the neck and occiput is a valuable agent in relieving pain and restlessness, but this should seldom take the form of blistering especially as the patient lies upon his back, and a large blistered surface in contact with the pillow and supporting the weight and pressure of his head and neck is liable to be followed by very unpleasant results. Mustard poultices fulfil every requirement and they can be repeated as applied if thought necessary during the illness.

Blisters to the scalp are used by some physicians. Their utility is very doubtful. They should not be tried except where for some cause the ice-bag or cold applications cannot be used, and, moreover, they produce great discomfort in the early stages of the affection.

Where these measures fail to relieve headache and induce sleep the important question of administering Opium crops up. About this there have been very varying opinions held but it may be said that those who have most experience express the least hesitation in giving it. Since the discovery by Lepine of the analgesic properties possessed by the new antipyretics there is not the same difficulty about relieving headache and the writer has employed antipyrine with much satisfaction in small and frequently-repeated doses in meningitis. Sulphonal or Chloral may be given to induce sleep when the pain is relieved by other measures.

Bromide of Potassium is sometimes of use in allaying cerebral excitement, blunting pain, and inducing sleep, but, as a rule, only disappointment is to be expected from it in severe cases. It may, however, be freely given when convulsive seizures are a prominent feature in the case. It can be also given to great advantage in combination with antipyrine. The following is a good formula —

R. *Sodii Bromidi* ℥iv.
 Phenazoni ℥j.
 Tincturæ Aconiti ℥xii.
 Aquæ Chloroformi ad ℥vj. *misce.*

Fiat mistura *Cpl. ℥ss quater in die.*

Iodide of Potassium in large doses may be tried with some hope of success where vomiting and gastric derangement are absent, and in the later stages of syphilitic meningitis it may be very valuable. It is also of value in causing the absorption of lymph, which would otherwise produce hydrocephalus by blocking of the drainage-channel of the brain, and the drug should be pushed even in the case of infants.

Vomiting may be best relieved by giving small pieces of ice to be swallowed whole, and by administering a plain effervescent mixture containing a few minims of *Liquor Morphine* with *Hydrocyanic Acid* and *Bismuth*.

Aconite alone, or combined with bromides, is of value where there is much fever and rapidity of pulse, with a dry skin.

Cold douches and Cold Affusion have been successful, especially in cases following exposure to the sun or strong heat.

Where the headache, delirium, fever, and insomnia appear to be uninfluenced or aggravated by these measures, and the disease appears to be rapidly passing into the state of exudation, the advisability of Blood-letting should be considered. Cases are upon record where this remedy appears to have been the means of cutting short the attack and saving life; and since the duration of the disease is often so short, the extraction of blood is not likely to be followed by an asthenic condition dangerous to the patient's ultimate recovery, as is the case in affections running a chronic course.

The writer's experience of blood-letting for meningeal inflammation is unfortunately confined to one fatal case, but he would not hesitate to employ it again in a suitable case after the ordinary remedial agents had failed.

When exudation has already taken place, as evidenced by stupor and approaching coma with alteration of pulse and pupils, some recommend blood-letting even at this stage; but there are good reasons for believing that when coma has set in the indications for venesection have passed away. When the patient is still able to swallow, Iodides may be pushed in large doses if not already administered; but should they have been given from the first, there is little hope to be gained from a further trial.

Purging may now have a chance, and a saline cathartic like the *Hospital White Mixture* may be given, so as to produce frequent watery evacuations every two or three hours, and there have been rare examples of the benefits of this measure even when stupor

bordering upon coma had supervened. Croton Oil may be given when swallowing is impossible or difficult. Any benefits to be obtained from this treatment may be expected to show themselves very soon, and it is obvious that it cannot be long continued.

Supposing the case to have gone on from bad to worse and coma to be now established, is the physician to surrender his arms and retire from the contest, or is he to content himself with ice to the head or blistering of the scalp? Doubtless by leaving all cases to nature the physician may once or twice in a life-time see a recovery.

When one studies the reports of the active treatment of the last generation of practitioners, two conclusions may be safely arrived at—(1) That some lives have probably been sacrificed to injudicious and indiscriminate leeching, blistering, purging, and blood-letting, especially when commenced at an early stage before a correct diagnosis was possible; (2) that at a later stage in apparently desperate or hopeless cases, a larger proportion of recoveries may be noted after such treatment than occurs where simple expectant measures are employed.

The writer has witnessed such unmistakable benefits follow the free use of Mercury that he is driven to the conclusion that to withhold this remedy in desperate or apparently hopeless cases of simple meningitis is unjustifiable. He is aware that this is strong language, and that by taking such a position he lays himself open to the censure of those who refuse to believe in the efficacy of drugs where the *modus operandi* of their action is not open to demonstration.

Nothing is easier than to cry "*post hoc non propter hoc*" when recovery follows salivation, but he who witnesses the rapid recovery of consciousness after the inunction of mercury in a patient who has remained in a state of coma, with insensible pupils, local paralysis, squint, &c., will be slow to attribute the recovery to nature, since without the employment of the drug he never has witnessed the same astonishing phenomenon when the case has been treated with other drugs, or left alone.

Given, then, a case of simple meningeal inflammation, in such a stage as that just referred to, there should be no hesitation in vigorous mercurialisation by rubbing in the B.P. Ungt. Hydrargyri for 30 minutes into the skin on the front of the abdomen, groins, and armpits. Where no evidences of improvement or of salvation are forthcoming, the inunction may be repeated in 12 hours again. In the case of very young children, it is very difficult or almost impossible to salivate them.

It is no objection of a serious nature to urge against this plan of treatment that there is a possibility or probability of the presence of tubercle. Such an event may not be capable of demonstration, and if tubercle exists the case is one which, in the present state of our knowledge, we are in the habit of regarding as one which is certain to end in a fatal issue.

The writer has satisfied himself that he has seen at least one patient who was snatched from death by this treatment, after coma and paralysis had lasted nearly a week, and he has repeatedly witnessed surprising amelioration of the symptoms and return of consciousness even in cases undoubtedly of tubercular nature. In the case just referred to there could not have been any syphilis, and the patient is still living and perfectly healthy since the attack—25 years ago. In meningitis from fracture of the bones at the base of the skull, Hutchinson strongly insists upon the benefits of early salivation, which he says is harmless. (See also page 382.)

When the acute symptoms have passed away, the greatest care will be required in dieting, a return to animal food or stimulants being likely to be followed by a return of the headache. For a long time absolute rest and freedom from all excitement must be insisted upon, and tonics or iron should not be resorted to till the patient is able to move about. Bromides and Iodides combined afford the best treatment at this unfortunately rare stage of the malady. Rectal feeding may be necessary during the prolonged coma, when swallowing is impossible.

Chronic cerebral meningitis being secondary to other affections, its treatment will consist in the remedies applicable to the primary lesion.

In the valuable paper by Lees and Barlow in Allbutt's System, the great value of puncturing the membrana tympani is pointed out, and often life may be saved in this way in the basilar meningitis of children, even after retraction of the head has been observed for many days. The tympanum should be incised on both sides as soon as the symptoms are marked, without waiting for a diagnosis between otitis and meningitis, as both are often present together. These authorities recommend the application of leeches behind the ear, iodides, and mercurialisation, and puncture of the lateral ventricles in some cases where hydrocephalus has remained after the meningeal symptoms have subsided.

MENINGITIS, Cerebro-Spinal.

The epidemic forms of this affection, also known as Cerebro-Spinal Fever, are so variable in their symptoms and degrees of severity, that there is much difficulty in giving any outlines of treatment which will be applicable to the majority of cases coming under the notice of the physician, especially since it has been observed that agents of use in one outbreak have been found to be productive of mischief in others. No drug can be said to exert any specific action upon the disease, but various remedial agents have been found to control or modify the symptoms and to tide the patient over the critical stages of the affection, so as to give nature a chance of asserting her influence.

The patient should be placed in bed in a quiet, darkened, well-

ventilated room, with his head and shoulders slightly raised by pillows, and the general treatment applicable to cases of cerebral meningitis may be adopted.

In sthenic examples of the disease blood-letting may be necessary, either in the form of venesection, wet cupping to the spine and occipital region, or leeches applied to the same localities. Smart purging is sometimes useful. In asthenic cases, or where collapse ushers in the disease, the opposite line of action must be promptly taken by administering alcoholic stimulants and concentrated nourishment in free and sometimes even in unlimited amounts, with warmth and sinapisms to the surface.

Pain calls for analgesic remedies, and most authorities use Opium or Morphia liberally. Some authorities regard Opium as the only remedy to be relied upon all through the attack and Stille gives 1 grain every hour or two hours, and affirms that it is not only palliative, but curative.

Cold compresses, evaporating lotions, or the ice-bag, not only relieve pain in most cases, but they appear to have some beneficial action, as in cerebral or spinal meningitis. Occasionally cases have been met with where warm applications have given relief and very hot water may be applied to the spine without risk when the pain is very severe.

High temperature may be relieved by the cold pack or by antipyretics, or the new febrifuges may be tried. Warm or even hot baths or packs may be indicated when the asthenic types of the disease are met with.

Quinine has enjoyed some reputation in cerebro-spinal fever but its usefulness is denied by many. It would probably act best in malarial forms, or where the fever was running very high, or in asthenic cases. To be of use large doses should be given at short intervals.

Bromides, combined with Belladonna, Morphia, Ergot, Antimony Chloral Digitalis, Gelsemium, and Aconite, have been recommended, but any benefit obtained is probably owing to the action of the bromides in this stage.

When effusion has taken place the same measures whose utility has been discussed under the head of Cerebral Meningitis may be tried.

These are (1) Blistering, (2) Purging, (3) Iodide of Potassium, (4) Mercury. Iodide of Potassium is the least objectionable of these methods. It must be given in full doses to be of any use and 15 grains may be given every 5 or 6 hours. Where it fails in showing any signs of causing absorption of effused products, and where these are manifestly incompatible with life, owing to the pressure which they are exerting, there is nothing left but to bring the patient rapidly under the influence of Mercury by rubbing in the ointment.

Blisters may be tried at a later stage if Mercury succeeds in warding off the urgent symptoms, and they may be very useful in

very chronic or prolonged cases alone, or in conjunction with the continuous current, massage, hydropathy, &c.

The value of Lumbar Puncture is very doubtful, except as a means of verifying the diagnosis. An aspirator needle is thrust into the intervertebral space midway between the spines of the third and fourth or fifth and fourth lumbar vertebrae.

MENINGITIS, Spinal.

The treatment of this affection is to be carried out upon the same principles as are applicable to the management of Cerebral Meningitis, and need not be dwelt upon in detail. They are the same for spinal pachymeningitis, arachnitis, and the varieties of spinal leptomeningitis, and they may be summed up thus —

Absolute rest in the horizontal position on the left side or face upon a water bed.

A diet chiefly of milk and farinaceous foods, with little or no stimulants.

Local bleeding by leeches and wet cupping on each side of the spine.

The free use of cold, as with the spinal ice-bag or cold compresses, especially in traumatic cases or where hemorrhage is suspected.

Where these cannot be borne, warm poultices or spongio-piline wrung out of warm or moderately hot water may be applied.

At a later stage, the application of narrow blisters applied along each side of the spinal column, but the danger of bed-sores must always be strictly guarded against.

Free purgation by saline cathartics.

The internal administration of large doses of the Iodides in combination with remedies calculated to relieve pain, as Hyoscyamus, Morphia, Antipyrine, Indian Hemp, and Bromides with Chloral.

Mercury may be tried in small doses. The results of salivation byunction are not so satisfactory as in cerebral cases. Iodot and Belladonna have been tried, upon the theory that they influence the circulation in the smaller blood-vessels in the cord and meninges, but they seldom do any good.

At a later stage hot baths, alternately with warm packs and hot douches, are of unquestionable value. The hot brine baths of Drottwich may be of use in the late stages of very chronic cases, or a sojourn at Aix may be beneficial.

A weak galvanic constant current passed from the occiput to the sacrum is highly recommended by Erb.

See further details discussed under the article Myelitis.

MENINGITIS, Tubercular.

The chief measures from which any results are to be expected in this almost hopeless malady are detailed under Cerebral Meningitis. Where the diagnosis is beyond a doubt (which it seldom, if ever, is) the more active agents, especially blood-letting, blistering,

and severe purging, are clearly contra-indicated. These measures may be here briefly enumerated—Absolute rest in a darkened, quiet, well-ventilated room, with the head elevated, a diet of cool milk frequently administered in small quantities, and one small Calomel purge at the beginning of the disease. Cold to the head, by means of ice or evaporating lotions after the hair has been shaved off the scalp, counter-irritation by sinapisms applied to the nape of the neck. Bromides or Antipyrine to relieve headache which has resisted the above agents, Opium being of very doubtful utility. Chloral or Sulphonal may be given to induce sleep.

Iodide of Potassium is the routine remedy to be administered in ordinary typical cases of the disease. It may be given with advantage in combination with the bromide, but full and frequently repeated doses are necessary if given at all. A child two years old may get 2 grains of the iodide and 4 of the bromide every two hours while the stomach is able to retain it.

Forced nourishment by milk should be carefully attended to throughout, and where milk is refused beef-tea or chicken soup may be substituted, though animal food in any form is to be objected to as long as mild farinaceous foods, or eggs, are swallowed and digested.

Where, in spite of these measures, the case goes on from bad to worse, and as stupor deepens into coma and the pupils become dilated and sluggish or fixed, the stage mentioned under Simple Cerebral Meningitis is arrived at, and the same problem is to be considered, and the physician is to decide whether further interference is justifiable. The considerations mentioned in detail upon page 568 apply for the most part here also. There is generally a doubt about the diagnosis being tubercular, and in this doubt lies the slender thread of hope of a successful issue. Where meningitis supervenes upon tubercular lung disease, or under such circumstances as leaves the diagnosis positive, the case may lead to its inevitable termination, but as long as any doubt remains, and as long as there is any reason to hope that the disease may be simple meningitis, the physician should rapidly bring the patient under the influence of Mercury by inunction. Against this procedure little can be said beyond that it will be useless in the opinion of those who do not believe in the efficacy of mercury to cause the absorption of effused inflammatory products, it cannot increase the patient's discomfort since he is already beyond the reach of feeling, and it is not likely to hasten the fatal issue. Mention need hardly be made of the possibility of its exerting an influence in destroying the chance of a natural cure, since this is supposed to be abandoned in the imaginary case under consideration. It may be worth while to state that the remarkable recovery before referred to under Simple Meningitis was in a patient the daughter of an hospital nurse. Her case was regarded as hopeless, as she was believed to be dying from tubercular meningitis by those who

had seen her, and after profound coma and squint had lasted several days, the writer, with the full consent of the patient's mother, rubbed in a large quantity of Mercurial Ointment more as a pharmacological experiment than with the hope of producing any marked amelioration of the symptoms. As a free and copious secretion of saliva poured out of the mouth some hours afterwards, the patient opened her eyes after a short time and rapidly gained consciousness and made a speedy recovery. The writer believed that the case was not tubercular, or such a favourable result would scarcely have occurred. In the light of further and recent experience he is led to come to a different conclusion, and to agree with Yeo, who comments upon this case in his invaluable work on "Clinical Therapeutics." Since then the writer has frequently satisfied himself that even in the undoubtedly tubercular form of the disease, mercury has the power of rapidly causing the coma or stupor to clear off for a time before death.

In late years the operation of tapping the subarachnoid space in the lumbar region of the cord has been frequently practised. An aspirator needle is pushed through the tissues between the third and fourth lumbar spines about one-eighth of an inch from the middle line, and the space is tapped in the adult about the depth of $\frac{3}{4}$ inches, and at less than half this depth in the child.

The fluid is permitted to flow till it stops, and the operation can be repeated without risk to the cord for several times. Some improvement often follows, but the operation by common consent is now regarded as useless in preventing a fatal issue, or even in prolonging life, and often it fails in draining the ventricles.

Waterhouse and Wallis Ord trephined midway between the external occipital crest and the mastoid on the left side. After the escape of a little fluid a probe was passed up into the subarachnoid cistern between the medulla and cerebellum, and several drachms of serous fluid came away, and a drainage tube was left *in situ*. In five weeks the patient was well, but there was no proof that the meningitis was tubercular, though there were double optic neuritis and other formidable symptoms.

The various attempts made by others to drain the ventricles have nearly all proved useless, and the same verdict must be passed upon the procedures of injecting antiseptic liquids into the cranial cavity. Sutherland and Cheyne have made an opening through the cortex, and established a permanent drainage of the distended lateral ventricle into the subdural space with one success in a case of basilar simple meningitis.

MENORRHAGIA.

Profuse menstruation or excessive hæmorrhage from the uterus at the menstrual periods may be bracketed with

Metrorrhagia, or hæmorrhage occurring between the menstrual periods, and not necessarily arising from disordered menstruation.

These conditions being merely the result of constitutional or

local causes, no treatment can be of any permanent use which does not strike at the cause of the increased flow. Hence a proper treatment of menorrhagia will embrace remedies directed to such different disorders as the following. — Bright's disease, pulmonary, cardiac, and liver affections interfering with the circulation, mental disturbances, blood diseases as purpura or malaria, uterine ulcerations, cancer, tumours, and displacements, metritis, parametritis, subinvolution, ovarian congestion, climacteric disturbance, &c. Dudley sums up the whole question ably stating—"The treatment of menorrhagia in girls and very young women is often that of a systemic cause; the treatment in mature women of the child-bearing age is usually that of endometrial benign tumours or displacements; the treatment of the menorrhagia of spinsters is commonly that of benign tumours, and of women between the ages of 40 and 50 years usually that of malignant growths or myomata; the treatment during senility is often that of malignant disease." After or whilst appropriate treatment is being directed to these causes of profuse menstrual discharge, or of menorrhagia, certain routine methods of treatment may be pursued.

Rest in the horizontal position upon a hard bed or couch with light clothing and cold milk diet with dry biscuit, is, perhaps, the most potent of all the host of remedial agents ordinarily employed to check profuse hæmorrhage from the uterus. In many cases depending upon widely different causes, absolute rest in the horizontal position tides the patient over what would otherwise be a weary and exhausting period, which drugs can scarcely modify to any appreciable extent if the patient had not been moving about.

Ergot or Ergotin alone, or combined with large doses of Quinine is the best drug for routine treatment. It may be given in tea-spoonful doses of the liquid extract or in the pilular form, each pill containing 2 or 4 grains of Ergotin every six hours, or often in severe cases, or a solution of Ergotin may be injected into the buttock or uterine walls, or 5 or 8 grains may be administered as a suppository or medicated pessary.

The following combination is useful:—

R Ergotini (Bonjean's) gr. iiss.
 Extracti Cannab. Ind. gr ʒ
 Quinina Sulphatis gr iii misce.

Fiat pilula. Mille tales xxiv Sumat unam quartis hor.

Morphia or Cannabis Indica, given in doses sufficient to soothe pain and tranquilise the circulation without inducing narcotism is always of use.

Iron in anæmic, and Saline cathartics in plethoric cases, are of undoubted value.

Bromides in full doses are clearly indicated in ovarian irritation.

Hydrastis Canadensis in doses of 15 minims of the liquid extract, often succeeds even in cases where Ergot has been unsatisfactory.

Stypticin, *Digitalis*, *Actæa Racemosa*, *Hamamelis*, Chlorate of Potash, Oxide of Silver, Guaiacum, Rue, Senega, Savin, Strychnine, *Salix Nigra*, Creosote, Iodine, Iodoform, *Belladonna*, and a host of drugs have been regarded as specifics, but, with the exception of the first-mentioned, their action may be said to be generally disappointing.

Stypticin is the Hydrochloride of Cotarnine. It is prepared from narcotine, one of the opium alkaloids, and has been found to exercise much influence over uterine hæmorrhage. 1-2 grs. should be injected deeply into the buttock when immediate action is necessary, or one of Merck's tabloids every four hours in ordinary cases.

The following mixture may be tried :—

R. *Liquor. Morphine Bimeconatis*
 Tinct. Digitalis ana ʒij.
 Tinct. Hamamelidis ʒss.
 Tinct. Hydrastis ʒvj.
 Glycerin Pur. ad ʒij. *misce.*

Fiat mistura. Capiat cochlearium minimum tertius horis ex cochleario magno aquæ.

Astringents (when administered internally by the mouth) like Alum, Tannic, Gallic, or Pyrogallic Acids, Acetate of Lead, Sulphuric Acid, and Matico, are so uncertain or inoperative as hardly to be worth trial. Suprarenal Extract and Chloride of Calcium are alone reliable. The value of Gelatin is still doubtful.

Speaking generally, the treatment of increased or irregular flow of blood from the unimpregnated uterus by the administration of drugs in the ordinary way by the mouth is most untrustworthy when not backed up by measures calculated to remove the cause of the affection.

Local means of checking the hæmorrhage may be resorted to when the drain upon the system begins to tell upon the patient's strength, and when this becomes very evident, local methods must be adopted. In many instances a very hot vaginal douche has great hæmostatic powers, especially when the bleeding is from the lower segment or cervix.

Electricity used according to the method of Apostoli, has been found in many cases to check hæmorrhages which have resisted all treatment. The most suitable cases for this remedy will be found in those where the hæmorrhage is caused by uterine fibroids, or by subinvolution.

The positive pole should always be introduced into the uterus when a hæmostatic effect is required, and the negative applied externally by means of the clay pad. A current of 100 milliamperes is generally sufficient, and the *séance* should not exceed 10 minutes and in frequency should not be oftener than twice a week.

The hæmorrhage may be often checked and even permanently relieved by this treatment, though there be no diminution produced by the electrolysis in the size of the uterus. Many authorities condemn this treatment entirely, chiefly on account of the pain and destruction of tissue which results, and many affirm that it is liable to be followed by septic troubles. Where polypus can be easily and safely removed by surgical means, it is hardly necessary to say that the operation should not be delayed where serious hæmorrhages continue to tell upon the patient's strength.

When the hæmorrhage is the result of the presence of a multinodular myoma, the removal of the appendages arrests the growth and lessens or stops the hæmorrhage, but if depending upon the soft oedematous form of myoma, this operation is useless.

Intra-uterine injections of strong solution of Perchloride of Iron, Nitrate of Silver, pure Carbolic Acid, or Suprarenal Extract are sometimes employed. Their use is, however, fraught with considerable danger and should be left in the hands of the specialist. When their employment is considered absolutely necessary the cervical canal must be dilated to the extent of permitting their flowing backwards.

It is generally advisable to employ a contrivance upon the principle of the double-barrelled catheter, which, upon being inserted into the uterine cavity, will permit the fluid to flow out through one channel after flowing in by the other, and only a very small quantity of the liquid (under a low pressure) should be injected.

When intra-uterine medication is indicated, as a rule it will be found much better practice to fully dilate the os and cervical canal, after which the medicinal agent can be freely applied to the interior of the uterus. In this way the writer has successfully treated menorrhagia caused by subinvolution of the uterus, complicated with a granular condition of the lining membrane, by freely swabbing the interior of the cavity with fuming Nitric Acid as recommended by Atthill. The modern plan known as intra-uterine tamponade, of packing the uterine cavity with antiseptic gauze, gives reliable results, and has done away with the practice of intra-uterine astringents, and affords the most thorough and effective treatment of all forms of uterine hæmorrhage.

Where sudden and alarming hæmorrhages come on, threatening the patient's life, unless prompt action be taken to stop them without the loss of time entailed by waiting for the action of the above-named plans of treatment, plugging of the vagina may be urgently demanded. This performance has been fully detailed under Abortion, upon page 11. Blocking the canal with antiseptic

sponge tents may be resorted to with advantage before plugging the vagina.

Where much blood has been lost, ligatures applied near to the shoulders and hip joints may be utilized with the view of retaining the blood in the vessels and allowing coagulation at the bleeding area, and the injection of saline solution into the veins or subcutaneous tissue may be necessary. The administration of Chloride of Calcium, 30 grs. every four or six hours, or 5-10 grs. Suprarenal Extract, to increase the coagulability of the blood, should be resorted to.

It is advisable to always keep before the physician's mind the dangers and inconveniences which may be expected to follow the sudden checking of periodical hæmorrhages from the uterus about the climacteric period. In such cases heroic treatment is very seldom called for. As soon as any warning is perceived of a hæmorrhage already due or reasonably expected, a strong saline purge may be given, and in plethoric subjects, when time permits, this may be preceded by 5 grains of Blue Pill or 4 grains of Calomel.

After the action of the cathartic and absolute rest in bed, the following pill may be given every four hours :—

R. *Morphina Hydrochlor.* gr. $\frac{1}{4}$.
 Ergotini (Bonjean's) gr. i.
 Extracti Belladonnae gr. $\frac{1}{8}$. *misce.*

Fiat pilula. Mille tales xxiv.

When the attack has passed off, a pill may be given every night till the next period, and full doses of Bromide of Potassium should be given twice a day during the interval between the hæmorrhages.

In very anæmic subjects the Iodoform gauze vaginal tampon used every month has been found to cause the removal of the hæmorrhagic tendency after three or four periods.

MENSTRUATION, Disorders of—See under Amenorrhoea, Dysmenorrhoea, and Menorrhagia.

MESENTERIC GLAND DISEASE.

The treatment of this affection will in no way differ from that of enlarged tubercular or scrofulous glands in any other region of the body. Under Scrofula, Lymphadenitis, Tuberculosis, Peritonitis Tubercular, &c., will be found mentioned the following agents.—Change of air and scene, by removal to a sheltered sea-side resort, protected chiefly from the north and east, in which the patient can spend the greater portion of his time in the open air, nutritious foods in abundance, especially milk, eggs, butter, beef essences, &c., and in some cases, peptonised foods.

Of all drugs Cod Liver Oil stands easily at the head of the list. Next to it comes Malt Extract, or its combination with Cod Liver Oil.

Iodides, especially the Syrup of Iodide of Iron with Iodide of Potassium come next in value. Iron, Phosphates, Hypophosphites, Arsenic, Chloride of Calcium, &c., are mentioned under Scrofula.

The writer has obtained results in advanced cases of the affection which were most surprising, after all the above had failed, and the patients were steadily passing from one stage of emaciation to a worse. Indeed, a case of chronic enlargement and matting together of the abdominal glands should be mentioned before the physician pronounces the patient to be beyond the region of hope. The result of the numerous laparotomies of late years prove that abdominal tubercle is a curable affection. Under Peritonitis, Tubercular, will be discussed the value of surgical measures in abdominal tubercle, and a working hypothesis or theory of the writer's is put forward as an explanation of the striking cures and improvements which have followed abdominal incision in this disease.

The treatment from which he has obtained the highest satisfactory results referred to, consists in the steady and perseveringunction of Cod Liver Oil into the skin over the abdomen, the oil being also given by the mouth, alone or with Malt Extract and Creosote.

The unction should be carried out in the following manner - After a warm bath, the skin being thoroughly dried by friction with warm towels, a table-spoonful or more of Cod Liver Oil rubbed in by the palm of the hand before the fire into the back and sides of the abdomen, especially into the skin in the inguinal regions. A flannel roller is bound round the abdomen, reaching from the pubes to the lower part of the sternum. Over this, and covering it in at all points, is applied a broad piece of moderately strong mackintosh sheeting. The friction should be continued night and morning for the first four or five days, the same sheet of flannel being re-applied each time. Soon this becomes saturated with the oil under the impervious sheeting and as the patient twists or moves about during the day and night, the oil is rubbed in incessantly. After the saturation of the flannel, one fresh and free application need be made in the day. The patient's clothes or linen are not much soiled, but the odor becomes very objectionable to the patient's friends, though he soon appears to become insensible to the discomfort. The binder need not be changed oftener than once in ten days.

Though this treatment will be found of the greatest value in abdominal glandular disease, the writer has used it in various other wasting diseases in children, with the most satisfactory results since about 1873. He has repeatedly witnessed an ascites warranting a tapping operation, to disappear under its use without arising from glandular mischief. He was encouraged to persevere

with it in every case of this nature after observing its effects in one instance in an emaciated, scrofulous child whose abdomen seemed distended with fluid almost to bursting the umbilicus being protruded like the finger of a glove. The parents, believing the case to be hopeless, refused to permit tapping. The incision was, however, persevered with, and after many weeks the patient recovered. A large mass of enlarged glands, around which the great epiploon was probably matted and adherent, slowly and steadily disappeared. The patient is now a strong, healthy man. (See under Peritonitis, Tubercular.)

It is also somewhat astonishing to see how diarrhoea disappears under the steady application of the binder and Cod Liver Oil in such cases, and when constipation exists, it likewise is relieved by the friction and pressure.

METRITIS.

Metritis and endometritis are most frequently found occurring together, the most rational view being that metritis as an idiopathic affection does not exist, but when present is always secondary to endometritis. The modern view is that metritis is a combination of endometritis, myometritis, and perimetritis, with the endometritis as the essential factor. The chief indications for treatment are identical in each case, and, as these have been already detailed under Endometritis, they need not be repeated. (See page 273.)

MIGRAINE—See *Megrim*.

MISCARRIAGE—See *Abortion*.

MOLE PREGNANCY.

As soon as the diagnosis has been made clear by the escape of some of the characteristic vesicles or fluid contents of the uterus, and there is any evidence of hæmorrhage, the physician should proceed to remove the uterine contents without delay, by dilating the os by means of Barnes bags. At the same time Ergot should be given in full doses.

Where hæmorrhage is copious, plugging may be performed till the canal or os is sufficiently dilated to admit the dilator or finger; in some cases a laminaria tent may be necessary. After the dilatation has been accomplished in the absence of uterine pains following the internal administration of Ergot, Ergotin should be given hypodermically, and the uterus emptied by expression from above, after which the case may be treated as one of premature birth or abortion.

Though it is highly desirable that all the diseased products be removed from the uterus, nevertheless it is not advisable to ensure this by internal manual or instrumental means if possible, as there is danger of serious structural alterations having taken place in the uterine walls in some cases. For similar reasons the prolonged

administration of a mixture containing Ergot, Quinine, and Strychnine may be indicated, with the view of producing steady contraction and hastening involution.

MOLES,

Or hypertrophic growths of the skin, generally of congenital origin, may be removed, when the cause of deformity, by the application of caustics, and when of large dimensions by the knife, cautery, or Volkmann's spoon. Caustic Potash, made liquid by the addition of a little water, or Chloride of Zinc, may be painted on the mole and allowed to scab over. The Ethylate of Sodium and Nitric Acid are also used. Any caustic, indeed, may be employed which the experience of the surgeon gives him confidence in manipulating and managing. Deformity may be minimised by skin grafting or transplantation. Very large marks should be operated upon in small sections at a time, the region submitted to destruction being allowed to heal before a new portion is attacked. Baker advises in such cases that the mole be mowed or shaved off without going to the entire depth of the skin, so as to prevent puckering or contraction in the scar. Where the growth is on the dorsum of the foot, it is said to often lead to melanosis, and more in this region should be excised by the knife if they show any signs of activity.

MOLLITIES OSSIUM.

In writing about the treatment of a disease like the present, it is the stereotyped thing to say that every departure from health—digestion, appetite, sleep, rest, &c., is to be corrected, and the general tone of the system improved by rest, good food, fresh air, and tonics, &c. No more in this respect can be said for the general treatment of mollities ossium than of other grave conditions, and about its special treatment nothing can be said, for practically nothing is known. Phosphorus has been vaunted but its value is doubtful. Absolute rest is essential, and since the disease is so often associated with pregnancy, the question of inducing very early labour will often thrust itself upon the physician, though the fact must not be lost sight of that where the disease is still in progress the pelvis is almost certain to be dilatable. Unfortunately, however, if the gestation be permitted to go to full time the pelvic outlet may be found dilatable, whilst the

brim is unyielding, in which case Cæsarean section may be demanded.

After delivery it has been recommended and successfully carried out that both ovaries should be removed in order to arrest the disease which is certain to rapidly advance if pregnancy again occurs. By the surgeon performing Porro's modification of the Cæsarean section the body of the uterus and appendages are removed after the extraction of the child, the placenta being taken away *in situ* along with the body of the uterus so that a second operation is unnecessary.

MOLLUSCUM CONTAGIOSUM.

The only treatment of any use in the majority of instances consists in the removal of the small cystic growths. Hutchinson finds that, if seen in the very early stages, frictions with equal parts of the ointments of White Precipitate and Sublimed Sulphur will effect their removal. When upon the face, a small incision with a fine tenotomy knife and the thorough evacuation of their contents are all that is necessary. Upon the body they may be snipped out by scissors or the knife, or when very small and numerous they may be destroyed by Ethylate of Sodium Solution, pure Carbolic Acid, Nitric Acid, or other caustic. When very large a free incision into the tumour may be made, the contents squeezed out, and the cavity curetted.

Jaya has carried out successfully the plan of injecting into the tumour through its base 1 or 2 minims of a 1 per cent. Sublimate Solution, which causes the tumours to wither up and disappear without leaving any scar.

Where numerous clusters of small tumours exist close together, a 10 per cent. Salicylic Acid Collodion may effect their destruction.

MOLLUSCUM FIBROSUM.

Excision by the knife and forceps, by the elastic ligature, by scissors, or by the galvano-cautery, is the best practice. Where the tumour is large the *écraseur* may be necessary. The method of electrolysis by using the needle, as in the destruction of small nœvoid growths, has been found to succeed without causing any mark after the shrivelling up of the tumour.

MORPHIA HABIT—See Opium Habit.

MOVABLE KIDNEY.

No treatment is called for in most instances where a movable kidney exists; but when severe pain and inconvenience follow the displacement of the organ the patient should lie down and rest in the horizontal position, with the head low and the pelvis slightly raised. In one case the writer found a patient writhing in an agony, and screaming for relief, urine being voided in drops, owing to most severe tenesmus, which came on very suddenly,

after some exertion. The presence of a floating kidney being suspected from a previous examination, without waiting for chloroform, morphia hypodermically, hot stupes, or the usual methods of allaying formidable spasm, he immediately caught the patient by the heels and thoroughly inverted the body. Instant relief followed.

Recurrence of such attacks may be prevented to a great extent by applying a firm bandage over the abdomen after the organ has been restored to its normal position, and if the parietes are very much relaxed, as in those who have borne a large number of children, a hard or smooth inelastic pad may be placed over the movable kidney, and a skilfully-made abdominal belt constantly worn. Niehan's truss may be tried.

Stitching of the movable organ to the abdominal walls has been successfully accomplished, and even extirpation, or nephrectomy has been performed. The best procedure is to perform nephrectomy by exposing the kidney through a lumbar incision, and stitching the capsule or areolar tissue which surrounds it to the muscles divided by the incision. The more certain plan, however, is to pass a number of sutures through the renal tissue. The mortality of the operation is about 3 per cent.

Where this condition is associated with ptosis of the liver, Campbell fixes both organs at the same time through median and posterior incisions.

Myles dissects off a portion of the renal capsule. He had an opportunity of removing a kidney which some time previously had been fixed by this method, and experienced the greatest difficulty in separating the organ, owing to the firmness of the adhesions.

MUCOUS PATCHES OR TUBEROLES—See Condylomata.

MUMPS.

The treatment of this affection is very simple and were it not for the fact that orchitis or meningitis and according to some authorities ovarian and mammary inflammation has been found to supervene, nothing whatever might be done. The chief indication is to keep the patient protected from draughts, and the swollen region covered by warm, dry dressings. A pad of absorbent cotton wool covered by a layer of oiled silk is all that is necessary in most cases. Where the tension gives rise to great pain and inability to open the jaws, a hot fomentation or warm poultice may be applied, but cold lotions had better not be employed. Extract of Belladonna may be smeared over the poultice. Should the pain continue, with much throbbing and local increase of temperature, suppuration may be feared, though the event is very rare, and in this case continual poulticing with warm or hot fomentations should be persisted in till the presence

of matter is rendered certain by fluctuation, when a free incision should be made, and the wound treated by antiseptic lotions.

Owing to the difficulty of opening the jaws, fluid nourishment is essential for several days till the swelling subsides. Where there is much increase of temperature and constitutional disturbance, Antipyrine or Tartar Emetic or a mixture like the following may be given:—

R. *Tinctura Aconiti* ℥xxxii.
 Liquor. Ammon. Acl. ℥i.
 Syrupi Croci ℥iv.
 Aqua Camphora ad ℥ii. *misce.*

Fiat mistura. Capiat cochlearium minimum secundis horis.

The complications are to be treated upon general principles, and there is still amongst the older practitioners a belief in the metastatic nature of the orchitis, meningitis, or ovaritis, which leads them to apply a smart sinapism or sharp counter-irritant to the parotid region when they notice signs of metastasis.

Martin maintains that the exciting cause of the disease exists in the mouth, and spreads through the ducts to the parotids, and he therefore insists upon antiseptic mouth washes, both as prophylactics and curative agents.

The writer has recently seen a case in a thin woman of middle age where a painful tumour suddenly appeared in the abdomen, evidently an enlarged and tender pancreas, and death threatened from the exhaustion of incessant vomiting. The symptoms yielded to rectal feeding and Morphia hypodermically.

MYALGIA—See Rheumatism, Muscular.

MYELITIS.

The treatment of this affection will for the most part embrace the management of whatever factor has caused the inflammation of the cord, as often the myelitis will be found to be secondary to injuries, wounds, diseases involving the spinal structures, hæmorrhage, or spinal leptomeningitis. From whatever cause, rest as near to being *absolute* as possible should be insisted upon from the onset of the first symptoms. The best position is the horizontal. Most authorities insist upon the danger in permitting the spine to become the lowest part of the body, and recommend the lateral posture with occasional change to the prone. The nursing is of the utmost importance, and a water bed is of the greatest use and in some instances it is essential for the prevention of bed sores, which often are the cause of death in this affection.

applications.

The diet should be milk and farina followed by soups and beef essences.

Drugs are not to be much depended on; sometimes Mercury has been found to be given in small doses, and the perchloride of Mercury by inunction is contra-indicated in some cases. Ergot, though theoretically is found to do much good. More may be said of Iodide of Potassium, and Belladonna.

Galvanism is indicated only after all other means are exhausted. The continuous current from 15 to 20 Volts may be used by placing one large moistened electrode over the upper part of the spine, and the other over the lower part. The electrodes should be not only wet with liquid, but they should be warm. A saturated solution of salt in hot water answers perfectly. The current should be continued long enough for each *seance*. The electrodes should be moved down the spine, and the applications repeated more than twice in the day.

At a later stage Massage and Faradisation with Phosphorus by the mouth, and Strapped muscular substance or subcutaneously may benefit, but this latter drug should never be used in the acute stage when great exaggeration of the disease exists. Counter-irritation is occasionally useful. In the chronic form of the disease is often most useful with Massage and Faradisation in those cases where the muscles are flaccid and wasted. The writer has seen the judicious use of Corrigan's button.

The treatment of bed sores, which are

used to relieve retention of urine, which sometimes occurs without the patient being aware, and the physician should be upon his guard lest he mistake the dribbling of an over-distended bladder for incontinence.

MYOPIA.

Attention should be paid to the amount and nature of the work imposed upon the myopic eye. If more attention was paid to the printing, type, and paper entering into the ordinary school-books, and if the "result fees" system was done away with, there probably would be less myopia. Where pain or aching follows the use of the eyes all school work should be given up entirely for a short period, and after the complete rest has removed these symptoms, shorter school hours, better print, and clearer light should be provided.

Special attention should be paid to the position in which school work or reading is done, and the common habit of bending over a table corrected. The head should be thrown well back, and all tendency to congestion of the eyes avoided.

The optical treatment will consist in the proper selection of suitable concave glasses. These will consist in spectacles or eye-glasses for distance and for reading. These latter, as a rule, are better to be a little more than half the full correction, except in very low degrees of myopia, when glasses which fully correct the error may be used. In the higher degrees it is a good plan to disorder the accommodation by instilling Atropine, so as to prevent the otherwise powerful efforts at accommodating. In very mild cases, resulting from overwork, especially when the eyes have been long and persistently fixed upon minute objects, and where myopia may be said to be commencing, the proper treatment will be to insist upon proper rest to the eyes and the instilling of a drop of weak Eserine Solution every night for a couple of months.

In cases of high myopia, removal of the lens has lately been tried with very good results. It causes a lessening of the myopia by from 12 to 20 dioptries, so should only be done in cases where the myopia is over 20 D, except in children with progressive myopia of 12 D or more. In these last cases the best results are obtained. The lens is needled, and after some time what fragments remain unabsorbed can be removed by extraction.

MYXEDEMA.

It is of considerable importance that the functions of the skin should be most carefully attended to, and the patient should be clad in flannel from head to foot. It is a significant fact that in those cases where remedial agents have been found to retard the progress of the disease, their rationale may be explained to a great extent by their diaphoretic action. Thus, the various forms of hot, warm, or vapour baths persistently employed have been followed

injection of Thyroid Extract, till finally many cases have been proved to result in the extract by the mouth in the ordinary partially cooked gland or its juice may be used. Preparations of the sheep's thyroid are now available in liquid or glycerin extracts and powder, and the tabloid form supplied by many of the manufacturers. The dried thyroid of the B.P. The various preparations of Iodothyron, Arodin, Thyroprotein, Thyrocollodin are also recommended, but it is difficult to possess any advantage over the entire gland. The dose of dosage is somewhat difficult, and at first is about 5 grs. of the dried gland daily at first, and the effects closely watched. Generally the mistake is made of giving too much at the beginning of treatment. The temperature should be taken as a guide to dosage, as soon as the temperature has fallen, the dose may be slightly diminished, and the symptoms of myxedema have almost disappeared. It is not easily be calculated which will keep the patient of his life in a perfectly normal condition. The patient under observation who was a case of disease in an advanced form, and the treatment should be maintained by the administration of thyroid extract. The aim should be to administer as much of the extract as will correspond with the output of the normal gland, as determined by close observation in every case.

Amelioration of all the signs and symptoms in rapidly the subnormal temperature increases, the nitrogen in the urine is as normal, the appetite increases, and the patient is his former self. (See chapter on the treatment of myxedema.)

small, superficial, and upon the trunk or covered parts of the limbs, it may be left as long as it remains stationary. Even when on exposed parts, an operation should be only decided upon after waiting some time, unless the growth is deep or showing signs of spreading, or where it is unsightly and has remained for so long a time as to negative the hope that spontaneous cure may result.

The means of treatment to be adopted will depend upon the size, depth, and locality of the nævus. Thus, when situated upon the trunk, some method which will effect its speedy removal without much regard to the size of the cicatrix, is to be preferred to the slow and often tedious plans, which, for the sake of sightliness, must be selected when the face is the seat of the affection. If the surgeon determines to attack the growth without destroying or cutting the skin, a host of plans have been tried and recommended, many of which, such as pressure by bandaging, or by the constricting effect of painting on Collodion and astringents, by applying cold by means of Ice, Ether Spray, &c., are utterly useless.

Measures with the view of exciting adhesive inflammation or coagulation of the contents of the tumour, so as to seal up the vascular tissue of which it is composed, offer many advantages. Those will be enumerated which have most frequently been found successful.

Blistering by Cantharides, Croton Oil, Tartar Emetic, Chloral, Corrosive Sublimate in strong solution, Saturated Alcoholic Solution of Iodine, or Strongest Liquor Plumbi has been practically abandoned in the face of surer methods, and the same may also be said with nearly equal truth of the old method of vaccinating the child with vaccine lymph, over the situation of the nævus.

The method of injecting various substances into the interior of the tumour to cause coagulation or inflammation, at one time so much praised, is now steadily becoming obsolete, owing to the great danger of injecting the agent into the circulation and causing sudden death by the formation of emboli. Solutions of Iron, Iodine, Ammonia, Tannin, Nitrate of Silver, and Pure Carbolic Acid, Creosote, or Absolute Alcohol have all been tried, and by most surgeons rejected, notwithstanding the recommendations to apply a clamp or ring round the nævus, or to break up the interior of the tumour with needles, in order to prevent such accidents.

Of much the same nature is the plan of inserting setons or irritants, as threads and hot needles, into the tumour, and the result is, though less dangerous, about equally unsatisfactory.

The only really reliable and unobjectionable method of exciting coagulation in the tumour is by Electricity, and it affords, after all, by far the most satisfactory all-round plan of treating nævoid growths with safety and with the minimum of disfigurement. It is generally spoken of as the electrolytic method, or the method by electrolysis, but, as pointed out by Duncan, this is a misnomer, for whether the results are obtained by neurotic, vascular, trophic, or osmotic action, it is not by the decomposition of fluids and

any other method. Port wine marks are, however, little influenced by electrolysis.

Ligature, though generally successful, is a very painful operation, and the various plans of subcutaneous ligature are not always satisfactory. The destruction of tissue is so extensive, and the subsequent cicatrix so unsightly, that about the face the operation should not be undertaken, especially as the contraction of the cicatrix may seriously interfere with the normal positions of the eyelids and lips.

Upon the trunk the writer has employed the ligature with good results by passing underneath the growth two hare-lip pins at right angles to each other, and tying firmly the tissues by a stout silken thread, after which the pins may be immediately withdrawn, though he prefers to leave them *in situ* for 24 hours. After the strangulated growth falls off, the raw surface may be treated as an ordinary sore by antiseptic dressings.

Destruction of the growth by the application of such caustics as Chloride of Zinc, Potassa Fusa, Vienna Paste, Arsenic, &c., is most painful and unsatisfactory, and should only be undertaken in very exceptional cases. The same remark applies to the use of the actual or thermo-cautery, and to the method of inserting needles, which are afterwards to be heated by a spirit lamp. A small superficial nævus may be successfully dealt with by Paquelin's cautery, which can be drawn lightly over its surface or thrust into its substance.

Nitric Acid may, however, be painted over very superficial nævi with success.

Ethylate of Sodium has been introduced as a remedy for the treatment of nævoid growths, and as there appears to be much uncertainty or difference of opinion regarding the methods of using it to best advantage, it may be advisable to quote the words of Richardson himself. The writer has successfully employed it for the destruction of small cutaneous or superficial growths. "As a rule, I employ the Sodium Ethylate in practice, but I have many times employed the Potassium Salt in cases where it was important to destroy a structure very promptly. Whichever of the preparations is employed it should be in a solution made by saturating the alcohol with the element till a solution of S.G. 7880 is obtained, or by the addition of absolute alcohol to the crystallised salt until a solution is made of the same specific gravity. This solution should be kept in a cool place, apart from the light. Originally I recommended that a glass rod should be used in applying the solution, and with the potassium ethylate this is still advisable, but with the sodium solution it is not necessary. A good camel's hair pencil is all that is required. In treating nævi I first dry the surface with a piece of cotton wool; then with a brush I thoroughly coat the dried surface with the solution. The application causes always some effusion and redness, accompanied by a little pain, expressed by those who are old enough to describe

remain for a few days, then removed it, applied the solution over the red surface, rapid cure, but it was so painful as to require anæsthetic. I have, therefore, given it a but rather slower, method. After the solution has passed through it, on the third day, a fine needle shaped like the old cataract needle, and passing over the vascular surface underneath, and on with firm pressure with lint on the upper surface, so that blood flows out freely, but further escape is prevented by a dossal of lint charged with Styptic Coll. has quite ceased a drop of ethylate solution is dropped through the punctured opening, and a crust is left over the crust, and the crust is left as it is for four days more, and if at that time the crust remains under it, it must be treated by puncturing just as before. When at last the crust falls off, the cure may be considered as complete, and the crust to scale off by itself leisurely. In the treatment by this plan I have never seen the least failure, and although some cases have been more difficult than others, there has not been one failure. I have come to look upon the method as specific for the treatment of circumscribed nævus. In respect to the commonly called mother's mark or 'poor man's mark' so good a report to offer.

Excision or enucleation may be practised in the case of nævi upon the trunk. The results are rapid and satisfactory. The most trifling, some growths shelling out, some large. The results are rapid and satisfactory. The growth appears to be at the bottom of the growth in the skin.

as scarification. This, though generally failing in all extensive cases, is the best method where the staining is limited to small patches, but even then it is often unsatisfactory. Excision the ligature, and cautery are used in the mixed forms of naevus. Cutaneous or mixed naevi of the eyelids should always be treated by the method of electrolysis.

NAILS, INGROWING—See page 456.

NASAL POLYPUS—See Polyp.

NAUSEA—See under Vomiting, Dyspepsia, &c.

NECROSIS.

The cause of the bone mischief must receive attention from the first. If, for example, syphilis has been the probable starting point, remedies directed to this affection should be administered. Antistrumous remedies are indicated in a large percentage of cases, and when the lower jaw is the seat of the necrosis from phosphorus fumes, the patient should be urged to give up his occupation. As the drain upon the system is certain to be both severe and long, attention should be most carefully paid to the diet, purity and abundance of air, and proper rest. When abscesses form they should be opened early. This is especially true when the matter forms under the periosteum. The incisions should be free and deep. With these measures—i.e., rest, feeding, opening of abscesses, and remedies directed against the primary cause of the disease—the surgeon must wait whilst nature performs her part in separating the living from the dead bone, operative interference at this stage being bad practice. Where the sequestrum is superficial as in exfoliation, its removal is easily accomplished by enlarging the sinus and incising the soft parts when it may be grasped by a stout pair of dressing or necrosis forceps, or it may be prized out of its bed by inserting a strong probe or director under its freest extremity.

When the sequestrum is central or lying free in the interior of a long bone, surrounded by dense ivory-like tissue, its removal may present serious difficulties. The writer has seen a large loose sequestrum in the shaft of the femur defy the skill of several surgeons. In such cases Esmarch's bandage being applied under chloroform, the sinuses in the soft parts may be slit up freely, so as to thoroughly expose the cloacæ in the healthy bone. These must be enlarged before any attempt can be made to extract large sequestra; the gouge, chisel and mallet, or the bone forceps, may be used, but in many instances it will be better to trephine in the neighbourhood of the two largest cloacæ and connect the apertures so produced by two parallel incisions made by means of a Hey's or straight saw. The practice of attempting to remove the sequestrum through a small opening is, unfortunately, only too

pure carbolic acid to every hour, sponged with boiled water or saline. Cyanide or Iodoform gauze. The depend on whether thorough asepsis unfortunately, is the exception. If suppuration has occurred, the gauze loosen, and purulent discharge will be the packing must be removed the cavity introduced every 2 or 3 days according and the wound in the bone encouraged bottom.

In the more fortunate cases in which rendered absolutely aseptic, the gauze a day will be found quite firm and tight made to hasten recovery by the introduction some aseptic foreign bodies calculated to blood clot. The favourite substance decalcified cancellous bone in small pieces packed with this after the removal of the if it can be easily got is sutured over it and the skin wound closed, provision for drainage only.

Should suppuration not occur recovery. If the wound has been infected the whole free drainage and packing must be resorted.

Such cases have to face a slow and exhausting discharge. It is, therefore, have a liberal diet, tonics, and as much possible.

NEPHRITIC COLIC—See Stone in the

NEPHRITIS—See next page.

organic lesion. It would be well if we could only regard neuralgia not as a disease but as a symptom of disease of some part of the nervous system or of the viscera, just as we regard jaundice and dyspepsia as symptoms caused by many different diseases. In the present state of our knowledge it is unfortunately still necessary to think and act as if neuralgia was a distinct affection, since we cannot determine the pathological lesion which is the origin of the symptom in many cases.

The treatment of neuralgia will, therefore, resolve itself in the first place into the removal of the cause, when this can be discovered, and with this object in view the physician must search diligently for any departure from the ordinary healthy standard, and having found it he should proceed at once to correct it with the hope that its removal may be followed by the disappearance of the nerve trouble. Such rational treatment in no way interferes with the various methods by which pain is to be relieved. It cannot be too strongly stated that though the temporary relief of suffering should play an important part in the treatment of the various neuralgic conditions, it should not be regarded as the chief or sole principle upon which the physician should approach the management of a case of severe neuralgia, though it is true that he may find in some cases no other indication for treatment.

It is also not to be lost sight of that smart neuralgia may persist after the removal of the cause, which, in the first instance, induced the neuralgic condition in the nerve trunk or its branches, and this consideration should prevent the very common mistake of flying from one remedy to another in quick succession without waiting a sufficient time for that steady and continuous action of the drug which may be crowned by permanent success. It is only after the evident failure of such rational treatment that the scientific physician will feel justified in resorting to the various empirical methods which experience may lead him to hope as likely to prove useful.

Amongst the departures from health standing in the relation of probable causes of neuralgia is anæmia. It is the experience of every physician that anæmia and neuralgia often occur together, and that no treatment sometimes will give any permanent benefit till the anæmia is removed hence in every such case iron is indicated. The scale preparations, the tincture, saccharated carbonate, Bland's pills, or other preparations may be given according to the special indications present. Occasionally, indeed, it may be necessary to give one preparation for a time, and follow it up by another until the system is saturated with iron. As a rule, small doses of iron are useless, and in this respect the treatment of neuralgia by iron preparations is upon the same footing as is that of chlorosis, in which affection doses much greater than can be assimilated appear to be necessary to produce the best results. In another important respect chlorosis and neuralgia agree—the

Arsenic is a drug of the greatest value in the very chronic or obstinate forms, given in full doses for long periods, and a considerable time after the painful paroxysms; moreover, a valuable drug in cases not of anaemia, and the writer generally gives iron, or during the intervals when the is suspended. The Arseniate of Iron may be of $\frac{1}{2}$ grain in combination with Quinine formula.

Errors in nutrition must be remedied by the administration of large quantities of food as the appetite and digestion will permit. In these latter can be improved is to be or tonics and peptonised foods when need neuralgia which have resisted all treatment yield to overfeeding and Warr Mitchell treatment.

Massage, in as far as it powerfully aids digestion, is a valuable aid in the treatment.

Insomnia, diminished amount of sleep, work, high pressure, grief, and anxiety radical measures before the ordinary routine fair chance.

Gouty, rheumatic, or malarial conditions be met by Alkalies, Colchicum, Salicylates, or other recognised agents. Syphilis is Lead poisoning, which not infrequently is calls for appropriate management, in which

may excite neuralgia in distant nerves. Thus wet feet may induce facial pain, and, as a general rule, warm clothing and the avoidance of sudden variations of temperature are of as great importance in the management of neuralgia as is an abundance of pure fresh air and sunlight, with outdoor exercise and freedom from worry or other source of nerve exhaustion.

The treatment of pain during the paroxysms will call for prompt and powerful anodynes.

MORPHIA or OPIUM and their preparations are foremost amongst these. To be of use in relieving the pain of an attack, the narcotic should be given in a full dose. It may be administered by the mouth or hypodermically; the latter method is decidedly to be preferred. When the affection is not of long standing, there is some reason to hope that Morphia may prove curative. The experience of every physician shows that in a small percentage of cases pain does not return after being once subdued by a good opiate, and there are strong reasons for believing that this is the result of the opiate, and that the cessation of pain is not owing to the natural decline of the disease. The writer has several times satisfied himself of the truth of this statement, especially when treating neuralgia of the sciatic nerve.

Another important fact may be here emphasised—*i.e.*, that this happy and desirable result is more likely to happen when the opiate has been injected into the immediate vicinity of the affected nerve than if administered by the mouth. In closely examining this statement, it may be fairly supposed that the acupuncture is an important element in the treatment since excellent results have sometimes been obtained by simple puncture of the affected nerve trunk by a stout needle.

Acting upon this theory of the duplex nature of the action of the hypodermic method of treating neuralgia, the writer has obtained most encouraging results by combining the acupuncture and opiate treatments more closely than is ordinarily attempted. Thus, he takes the quantity of B.P. solution of morphia for hypodermic use, say 4 minims, and dilutes this with the full of a large hypodermic syringe of distilled water, making in all 20 or 30 minims of liquid. This he injects in several places *deeply* along the course of the affected nerve beginning at the level of the fold of the buttock, aiming at a puncture of the nerve trunk at each insertion of the needle, which should be made at right angles to the surface when the nerve lies deep. It is advisable to mark out the course of the nerve with an aniline pencil before beginning. The pain of the needle pricks is sometimes scarcely appreciated by the patient after the first two have been made. In sciatica he is certain that this is the best of all methods of treatment.

Where this plan is likely to succeed, the result will soon be evident, and the physician must be always upon his guard lest the opium habit becomes established during the management of a case of rebellious neuralgia by powerful anodynes. This much can be

by a full opiate administered by the mouth, may be combined with some other remedial agent, such as of Ammonium, &c.

COCAINE hypodermically is a valuable remedy for severe pain, and Gowers prefers it to morphine. It does more than relieve pain; it arrests the morbid impulses which cause pain. $\frac{1}{2}$ gr. will be sufficient.

Before proceeding to detail the numerous remedies for neuralgia which might accompany or follow a severe attack, it will be more convenient to briefly review the remedies which have been from time to time employed for the relief of the affection; and in detailing their uses, to mention the minor neuralgia of the face is supposed to be generally before the writer's mind.

CHLORIDE OF AMMONIUM may be considered as a so-called neuralgia specific. It has been found that full doses have the power of relieving the return of the paroxysms in some instances. How it acts in some and why it fails in others, we do not know, nor can we tell in what cases it is tried. The same remarks will apply to all other anti-neuralgic remedies, and in severe cases the physician will be obliged to become a mere empiric, prescribing one remedy after another, until he finds the one which removes the affection. The dose may be given every two hours for three days, and as a rule if relief be not obtained in a week, the remedy may be abandoned. It has been found useful in intercostal, visceral, and sciatic neuralgia, and in combination with the following.

QUININE, as already mentioned, should

paper. As a rule it is not necessary to push the drug till cinchomism is produced, but in obstinate cases this may be done before giving up the remedy.

By giving it before the expected paroxysm this may sometimes be effectually forestalled. The result is, however, more likely to be obtained in malarial cases. In neuralgia of the supra-orbital branch of the fifth nerve, quinine is perhaps the best remedy which we possess, and in patients who cannot tolerate the drug well, one grain may be given every 40 minutes in solution till five or six doses have been administered.

The following may be tried in obstinate cases:—

R. *Quinnæ Sulphatis* gr. v
Morphinæ Hydrochloridi gr. i.
Ammonii Chloridi gr. xv. *misce.*

Fiat pulvis. Signa—"One powder wrapped up in moistened wafer paper to be taken every six hours, after food."

ANTIPYRINE, ANTIPYRIN, PHENACETIN, and SALOL may be given in all forms of neuralgia, and sometimes they act with remarkable rapidity, though the same success is not to be expected as in the treatment of migraine. Recently a long list of new analgesics has been in use, including Phenocoll Hydrochloride, Apolysin, Citrophen, Salophen, Lactophenin, Neurodin and many compounds of Antipyrine, Euphorin, Analgene, Malakine, and Methylene Blue. Upon the whole it is doubtful if any of them possess any real advantage over those in longer use. The last mentioned has been extolled in sciatica when given in capsules in doses of 3 or 4 grs. twice or three times a day.

10 grs. of Antipyrine may be given as soon as the paroxysm begins, and 5 grs. every two hours afterwards for 3 or 4 doses. As a rule if relief is to be expected at all, it will follow before 20 or 30 grs. have been administered. In patients suffering from any form of neuralgia who are also migrainous these remedies appear to act remarkably well. The writer's usual formula is the following; it is especially valuable in visceral neuralgia:—

R. *Phenazoni* ℥ii.
Extracti Cocæ Liq. ℥ii.
Codemur gr. vi.
Glycerini et Aquæ ad ℥iv. *misce.*

Fiat mistura, cujus capiat cochlearium unum minimum ex cyatho cinario aquæ quater in die post cibos.

Salol and Phenacetin may be given in 10 gr. doses every four, six, or eight hours.

EXALGIN has been used by Fraser with success in various forms of neuralgia. The writer has used it in several cases of neuralgia in various regions; it appears to give relief without very material diminishing the tendency to future severe paroxysms. This may not be the result when larger doses are administered. The writer did not exceed one grain every three or four hours dissolved in a table-spoonful of water.

CANNABIS INDICA has been much employed in neuralgia. It does not appear to possess properties differing much from opium or morphia, but it is a valuable drug when for any reasons these are contra-indicated. It is more efficacious in neuralgias of the pelvic organs and in neuralgia occurring in migrainous subjects. $\frac{1}{2}$ to $\frac{1}{4}$ grain of the extract may be given in pill every four or six hours.

GELSEMIUM is one of the best remedies which we possess when the affection is confined to the dental branches of the fifth nerve. It appears also to act more powerfully when the lower jaw or alveolar processes are the seat of the trouble. It affords relief in some cases, even when the teeth are carious and when the pain arising from them. In one sad case which fell into the writer's hands after every tooth in the upper and lower jaws upon one side had been fruitlessly extracted from time to time during years of agony, gelsemium gave the first relief which the patient had enjoyed for nearly half his life-time.

It must be given in doses bordering upon the dangerous in some cases, and the writer found a patient holding on to a lamp-post in the street unable to articulate and suffering from ptosis and diplopia after taking two doses of $1\frac{1}{2}$ grs. each of the old B.P. alcoholic extract which had been ordered for neuralgia of the fifth nerve. There is much difference in the susceptibility of different patients, and, as a rule, it is well not to exceed the dose of 1 grain of the extract or 12 minims of the tincture until the patient has taken the drug for some time. These doses may be repeated at intervals of two hours till a painful feeling is experienced in the brows and eyeballs, followed by giddiness and some ptosis. As a rule, it is not safe to push the drug after ptosis has been noticed, or when the patient complains of double sight, or when staggering of his gait has been observed. The mental faculties not being in the least affected by poisonous doses the physician should not be misled by the clear and rational demeanour of the patient. Ringer has given drachm doses of the tincture every hour for six doses, with slight disturbance.

CHLORAL has been recommended, but it almost always fails in neuralgia. It is of some use, however, when applied locally as will be mentioned further on. Success occasionally has been achieved by administering a combination of chloral and morphia, but such a combination is likely to succeed only in cases which probably would yield to safer drugs and this combination is said to be a dangerous one by several physicians.

CROTON-CHLORAL or BUTYL-CHLORAL HYDRATE is a remedy of value for neuralgia of the fifth nerve. Ringer states that for facial neuralgia it is the most efficacious remedy which we possess. He uses it in the neuralgic pains arising from carious teeth, in the obstinate and severe facial attacks in old people, in neuralgia of the back of the head, occiput, and neck; and in migrainous shooting pains extending from these regions towards the shoulders. The writer has been generally disappointed in the use of this remedy, except when administered for minor neuralgia of the fifth nerve, when it very often succeeded in relieving pain and afterwards inducing sleep. For visceral neuralgia it appears to be useless. 10 grs. may be given, and 5 grs. repeated every two hours for three or four times. The pilular form is the best, and Gelsemium may be combined with it either in the form of extract, $\frac{1}{2}$ grain, or of Gelsemine, $\frac{1}{10}$ grain. This latter is Ringer's favourite method. He gives a pill containing $\frac{1}{100}$ grain Gelsemine and 3 grs. of Croton-Chloral every quarter of an hour for six or eight doses, then hourly. The writer has never had the courage to employ these drugs in such frequent doses. Liebreich has, however, recommended the Croton-Chloral as a harmless soporific suitable even in heart disease in doses of 60 grs. Alarming results have been observed after half this dose.

It may be administered with advantage in combination with Indian Hemp thus:—

R. *Gelsemium* gr. $\frac{1}{10}$.
Butyl-Chloral Hydratis gr. v.
Extracti Cannabis Indicæ gr. $\frac{1}{2}$. *misce.*

Fiat pilula. Miste tales xxiv. Sumat unam tertius horis.

ATROPINE and BELLADONNA, though more frequently used locally, are nevertheless, of use often in neuralgia. The writer has found them much more valuable in abdominal or pelvic than in facial cases. In sciatica he has occasionally seen Atropine succeed when given hypodermically in combination with morphia, when this drug had previously failed without the Atropine; and, since it diminishes the dangers which sometimes follow upon the injection of morphia, it is a wise rule always to combine one or two minims of the B.P. solution with every hypodermic dose of morphia. Trousseau's plan of treating neuralgia consisted in administering $\frac{1}{2}$ grain of Extract of Belladonna every hour until giddiness was produced, when he lessened the dose and prolonged the intervals for several days. These doses of the *Alcoholic* Extract of Belladonna might be poisonous.

Belladonna may be given in the pilular form combined with

HYOSCYAMUS, STRAMONIUM, and Hyoscyamine, way as belladonna.

IRON and ARSENIC have already been of value in the treatment of the causes of neuralgia. In cases where no evidence of any case of neuralgia will seldom come before the physician will not require either or both of these in its progress. It will be generally necessary to give them in slow or chronic cases, to when the pain has been subdued with all

Since most of the remedies already mentioned whilst severe paroxysms of pain are present, it follows that there are intervals more or less when the administration of the remedy is suspended. In these cases time should not be lost and in these intervals, or full doses of Fowler's Solution, or Fowler's Solution in combination with that of Iron and Quinine, should be steadily given. In this way the return of the pain is certain, and these drugs should be continued until the pain has subsided. Cacodylate of Soda in $\frac{1}{2}$ three times a day.

PHOSPHORUS is a remedy which in consideration appears to act pretty much as mentioned. The indication which is regarding to the administration of Phosphorus is nerve exhaustion resulting from excessive work under high pressure; and in it affecting any region of the body in older

PHOSPHIDY or ZINC ($\frac{1}{4}$ grain) may be employed instead of the free element, it is much vaunted, but Gowers states that it is of little value.

The HYPOPHOSPHITES, in the form of Fello's Syrup, are very valuable adjuncts to the treatment of neuralgia, though it is hardly necessary to say that as they contain no free phosphorus, their efficacy does not depend upon this substance; and the same remark applies to phosphoric acid, to the syrups of phosphate of iron, of Parrish, and of Easton.

Zinc preparations are often of use in the treatment of the various neuralgias. The best of them is the Valerianate, and it is especially indicated in hysterical cases and in examples of the disease where the head and face are affected, and where periodicity is more or less marked. Less than 5 to 8 grs. in one dose need not be given. It may be administered in the form of pills containing 3 to 4 grs. each, or it may be combined with as much Quinine, and may be swallowed in moistened water paper. Often the stomach rejects the dose, but the writer has seen it succeed in neuralgia which had proved rebellious to many other drugs. Other Valerianates may be tried, and the Quinine, Iron, and Ammonium Salts have each their advocates. Valerianic Acid and Valerian Root also are occasionally found useful.

The following pill is useful:—

R. *Quintina, Ferri, et Zinci Valer. ana gr. iss.*
Extracti Gelsemii gr. $\frac{1}{2}$.
Extracti Cannabis Ind gr. $\frac{1}{2}$. misce.

Fiat pilula. Mille tales xx. F. a. o. Sumat unam ter in die post cibos.

CAFFEINE, THEINE, GUARANINE, NAPELLEINE, CONIUM, CODEINE, NARCEINE, STRYCHSINE, ERGOTIN, and SUMMIT must be included in the list of anti-neuralgic remedies. Their indications are, however, very unsatisfactory, and, like many members of this class, they must be used more or less empirically when other drugs have failed. As a rule these substances may be said to be more likely to succeed in visceral neuralgias than in affections of the nerves of the head, face, or extremities except in the case of Caffeine, which appears to relieve facial neuralgia when given in large doses especially in migrainous subjects. A combination of Codeine and Strychnine is sometimes very useful in visceral neuralgia; it may be given in the following formula:—

R. *Ext. Nuc. Vom. gr. $\frac{1}{2}$.*
Codeina gr. $\frac{1}{2}$. misce.

Fiat pilula. Mille xxiv. tales. Sumat i. quater in die.

NITRITE OF AMYL, NITROGLYCERIN, and other Nitrites afford the best chance of success in cardiac neuralgic conditions and inhalations of the Amyl Nitrite sometimes cut short the paroxysms of neuralgia of the fifth nerve.

CHLOROFORM and ETHER may be used as inhalations to give speedy relief in desperate attacks of neuralgia in any nerve, but for obvious reasons such powerful and possibly dangerous methods of relieving pain must necessarily be very seldom resorted to.

ALCOHOL in large doses is open to the same serious objection and though it is a drug of much value in intensifying the effects of other narcotics, the physician must always be upon his guard in employing it in affections liable to run a chronic course, as in the establishment of the opium habit when morphia has been unwisely prescribed, the alcohol habit may be the terrible result of the physician's indiscretion in permitting the use of alcohol for the relief of pain especially in chronic cases.

IODIDES and SALICYLATES have been already referred to when detailing the treatment of the probable causes of neuralgia. The Iodide of Potassium, however, often proves very useful in cases where there is no history or suspicion of a rheumatic element or of a syphilitic taint. To be of use, however, it should be given in full doses, and less than 5 grs., speedily increased to 10 or even 20 grs. three times a day, seldom proves beneficial. It is very valuable in some rebellious forms of sciatica; and generally speaking, its administration is most clearly indicated in those cases of neuralgia which are characterised by nocturnal exacerbations, though, as already mentioned these need not necessarily be of specific origin. In neuralgia affecting the cardiac organ, and in the neuralgic pains apparently arising from the nerves which supply the long bones, the Iodides are of great value. Iodoform is sometimes administered instead of the Iodide of Potassium, but it has failed in the writer's hands.

CHLORATE OF POTASSIUM has been reported as successful in facial neuralgia, but the writer has never seen any benefit from it.

CIMICIFUGA has been found to relieve neuralgia of the fifth nerve and of the ovarian nerves. It is sometimes very useful in neuralgic conditions associated with muscular rheumatism, and it may sometimes be combined with much advantage with Iodides.

BROMIDES are of little use unless when given in combination with other agents. They may however, be used freely in this way with advantage, and for the insomnia attending some cases, full doses of the Bromide of Potassium, given at night, with Opium and Iodides, are productive of much benefit. Anstie spoke highly of the value of large doses of Bromide in cases arising from sexual excitement, and Gowers has found it useful occasionally in idiopathic paroxysmal cases occurring in irritable anxious subjects.

TOXA has been much praised as an anti-neuralgic remedy, and

sometimes proves very efficacious in facial neuralgia. It is believed to be a mixture of the bark and leaves of various species of *Rhaphidophora* and *Premna* from Fiji. The dose of the liquid tonga is one drachm three times daily. Often it fails entirely.

PULSATILLA, PISCIDIA ERYTHRINA, BEBEERU, CHELIDONIUM, APIOL, CHAMONILE, VERATRINE, DIGITALIS, and a host of other vegetable products have been used internally from time to time, but as most of them are now seldom employed, space need not be taken up with a discussion of their very doubtful merits as anti-neuralgics.

Local measures for the relief of neuralgia will be now briefly referred to though it must not be inferred that their employment is only to be undertaken after the failure of the previously-mentioned methods of internal treatment. In some cases purely local treatment may succeed but, as a rule, it should be employed at the same time, and as auxiliary to the internal administration of some of the remedial agents already detailed.

ACUPUNCTURE has many advocates, perhaps chiefly amongst surgeons and the writer, though he never employs this remedy alone, has seen very decided benefits follow its use in the hands of others. It is indicated in sciatica, and occasionally its effects prove as rapid in acute cases as they do in lumbago, but like almost every other remedy used in neuralgia, acupuncture fails utterly in many cases. A stout needle should be driven deeply into the tissues in several places over the course of the affected nerve, which should be punctured at each insertion. There does not appear to be any advantage in allowing the needle to remain *in situ* for any length of time. Acupuncture of corresponding painful spots upon the opposite side of the body has been reported as successful.

The writer's method of combining acupuncture with the hypodermic injection of a weak solution of morphia into the affected nerve has been already referred to upon page 505, and he may here repeat that he believes it to be the most efficacious combination of local and constitutional methods at the disposal of the physician in dealing with obstinate neuralgias. He combines with the dose of morphia $\frac{1}{10}$ grain of Atropine. The method obviously embraces the following agent—

ACUPUNCTURE, or the deep injection of a small quantity of pure water into the nerve or its immediate neighbourhood, has also given good results.

OSSIC ACID has been strongly recommended as an injection in sciatica, and the writer has employed it very many times in obstinate cases with success. Bilioth has found it cure sciatica which had resisted all treatments for years; he injected it deeply between the ischium and trochanter. The writer takes 15 minims of a freshly-prepared one per cent. solution of the acid, and dilutes this quantity with the full of a large hypodermic

syringe of distilled water : he injects this deeply into the nerve in half a dozen places, from the thigh to the heel, introducing a few minims with each insertion of the needle.

Of course, the nerve trunk and its branches are often missed the needle passing right through them or falling short of them, in some cases, but the physician should aim at lodging the injection in the nerve substance. It is evident that the success of this vigorous treatment may be altogether owing to the numerous acupunctures independent of any virtue possessed by the osmic acid. In using the hypodermic needle for acupuncture it is necessary to be careful lest it should break, as considerable force is generally needed in piercing the skin and deep tissues. There is no danger of such an accident if a short grip of the needle be taken by grasping it firmly between the finger and thumb, at a distance from the point supposed to correspond to about the probable depth of the sciatic nerve from the surface. It should be plunged in boldly, and a little Carbolic Acid be previously painted over an area as large as a sixpence where the puncture is to be made, little pain will be felt.

COCAINE may be employed in exactly the same way and $\frac{1}{2}$ grain may be injected in one or two places, though very much greater quantities have been injected without producing unpleasant results.

ANTHYRINE and other substances, such as Carbolic Acid, Turpentine, Creosote, Oils of Peppermint and Cloves, may be injected, but, as a rule, they produce great pain and may possibly lead to sloughing.

CHLOROFORM, injected in doses of 5 to 10 minims, has given excellent results in the hands of Bartholow.

GUAIACOL has many advocates ; 2 or 3 minims sometimes relieve pain promptly, but Anders injects this dose with 10 minims Chloroform and the results are striking. Pain often never returns after one or two injections.

COUNTER-IRRITATION is a long-established method of treating the various forms of neuralgia, and the different ways in which it may be employed are almost endless, when we consider that nearly every substance capable of irritating or blistering the skin has been at some time or other advocated as a specific for neuralgia.

Cantharides, either in the form of blistering collodion, or as small circular or narrow strips of blistering plaster, may be used. The latter are certainly to be preferred as they can be removed after a few hours' application in those cases where an effect short of real vesication is desired. They can be placed over the trunk or principal branch of the affected nerve, or over the centre of the most painful spot. Thus in sciatica, a blister $1\frac{1}{2}$ inches broad by 3 long may be applied over the nerve as it emerges from the pelvis. In two hours the blister may be removed and placed over

the upper part of the popliteal, where it may be suffered to remain for three or four hours.

Anstie laid down the rule that the blister should be applied over the posterior branch of the same spinal nerve trunk as that from which the neuralgic nerve springs.

In neuralgia of the face or scalp, relief may be obtained by applying a small circular blister over the temple or behind the ear, and allowing it to remain on till complete vesication occurs.

The actual cautery is still by some preferred to blistering. Valleix, after etherization, passed it lightly along the course of the affected nerve so as to produce superficial eschars. Many cases yield to this treatment after resisting every other. Corrigan's Iron may be used, after heating to a dull heat over the spirit lamp, or it may be dipped in boiling water and pressed upon the part. By graduating the degree of temperature almost any effect, from the mildest counter-irritation to the rapid destruction of the superficial tissues, may be produced. The thermo-cautery can be also used. Mustard poultices are highly recommended as a means of counter-irritating in neuralgia, though the writer has always chanced to see aggravation of the symptoms produced by them.

Capsicum, in the form of the Chili Paste, may be used with advantage in very chronic cases.

The plan of causing rapid vesication by the application of strong solution of Ammonia, and sprinkling morphia, strychnine, atropine, or other drugs over the excoriated surface, is now seldom employed.

Leeches applied over the centre of the most painful spot often give prompt relief.

Of local anodynes there are many which have proved useful. Thus—

MENTHOL, rubbed along the course of superficial neuralgic nerves, often affords speedy relief and Guaiacol acts in a similar manner. The Liniments of Belladonna and Aconite may be used in the same way, and Chloroform may be combined with them. The writer has employed the following to paint over the skin covering superficial painful nerves, chiefly about the face and neck :—

R. *Olei Caryophylli* ʒiv
 Olei Menthe Pip. ʒvi.
 Chloroformi Purificat. ʒii.
 Linimenti Aconiti ʒiv. *misce.*

Its application is often followed rapidly by marked relief, though like most other anti-neuralgic remedies, it sometimes produces no effect at all.

ATROPINE, ACONITINE, and VERATRINE Ointments are powerful local anæsthesics, and should be gently rubbed into the skin in the course of the affected nerves till numbness and tingling are experienced.

Intercostal neuralgia is said to yield sooner to the Belladonna than to the Aconite Alkaloid.

CHLOROFORM, ETHER, COMPRESSED CARBONIC ACID GAS, and METHYL CHLORIDE have been often found very efficacious in giving speedy relief to acute, agonising pain. Freezing of the part is not necessary to produce the best results, and sometimes should be avoided. In the use of the Methyl Chloride a few seconds application to any one spot is generally long enough to cause severe irritation, and even sloughing, may follow its use.

IOODOFORM, in saturated solution in Chloroform, AMYL CHLORIDE, ICHTHYOL, HYDROCYANIC ACID, OLEATES OF MORPHINE AND ACONITINE, equal parts of CHLORAL and CAMPHOR are amongst the many local anæsthesics vaunted as specifics for neuralgia. With none of this batch has the writer any experience.

SULPHUR externally sometimes gives excellent results. It should be freely sprinkled over the neuralgic region on cotton wool and then bandaged firmly. In sciatica the writer has had great satisfaction in many chronic cases with this remedy.

COLD.—The spinal ice-bag and the ice-cap have been tried but they very often greatly aggravate the paroxysm. The wet pack and other hydropathic methods may be safely tried in many cases of obstinate neuralgia, but, as a rule, dry heat gives better results than cold. Gowers points out the danger of applying heat to the peripheries of nerves the seat of neuritis.

ELECTRICITY, though only mentioned at the end of the list of remedial agents, is one of the most valuable methods which we possess for treating the various forms of neuralgia, but, like every other remedy mentioned, it often fails, and at present there is no known method by which we can venture to prophesy its success or failure before the experiment has been carried out. It is about equally valuable and equally worthless in visceral, facial, or sciatic neuralgia, and until tried, the relative value of each form of electrical treatment cannot be determined.

As a rule it does not practically matter about the exact position of the electrodes though the rule is laid down that to produce the most marked sedative effects the circuit should be closed with the anode over the affected nerve, and the kathode upon an indifferent region in the neighbourhood. The continuous current is most likely to give the best results. The electrodes should consist of large flat metallic plates covered over with several layers of warm moistened wash leather or sponge. One being placed over the trunk of the nerve, the other may be slowly moved up and down over the regions to which its branches are supplied. 10, 15 or 20 Leclanché cells may be employed. No shock or painful contraction of the muscles should be produced, and the application should

be continued for 5 or 10 minutes. The writer has observed neuralgia to disappear after a few such applications, though this is a comparatively rare occurrence.

In sciatica, the current from 15 to 25 cells may be made to traverse the lower extremity, and before lifting the electrode off the skin the various cells may be gradually cut off by using the handle of the switch-board so as to prevent a shock.

Where the continuous fails, the interrupted current may be employed. It is not advisable to use many cells and the interruptions should be rapid. When this fails, a strong current may be used as a counter-irritant. The writer has several times found patients who have used the common electro-magnetic machine with great benefit even in sciatica.

McClure speaks highly of static electricity, and he has made the important observation that during its use the action of internal remedies appears to be much intensified. In facial neuralgia he employs the soufflé by a metallic point for 10 minutes, and where this fails, he draws fine sparks by approaching it nearer to the skin, and finally he extracts heavy sparks by means of the metal ball, and he finds that occipital, facial, cervical, and brachial neuralgias readily yield to this treatment.

Kataphoresis is the name given to a method of employing certain substances locally by means of the galvanic current with the view of causing their absorption by the skin in such a way as they may reach painful nerves or diseased tissue. Thus a pledget of lint soaked in Chloroform is placed over the painful part in neuralgia, and the positive electrode is laid upon it, and a constant current passed through the part, the current being reversed every two or three minutes.

Pressure upon the nerve trunk, and the application of a succession of smart taps or vibrations generated by means of an ingenious apparatus devised for the purpose, have been followed by results which, as a rule, can be more readily obtained by other remedies.

When a case of neuralgia has proved rebellious to the various remedial agents already enumerated, the question of surgical interference must be seriously considered. Before finally deciding it will be worth while to try massage and a change of climate, when the patient's means and the nature of his neuralgia will admit of such a step. A dry, warm atmosphere may be tried. A long sea voyage often gives excellent results, and does away with the necessity of surgical operations.

The following are the various procedures which have been successfully practised for the relief of obstinate neuralgia —

Nerve-stretching, Neurotomy, or section of the nerve, Neurectomy, or excision of a portion of the nerve, Nerve-avulsion, or the tearing out of a nerve-trunk from the bony opening through which it passes; and Nerve ligature.

Nerve-stretching is performed in two very different ways. The first, or minor method, known also as bloodless nerve stretching,

should always be tried before resorting to the cutting operation, when the anatomical position of the nerve permits. The kneading method can be easily carried out in the case of the sciatic nerve. The patient being thoroughly brought under the influence of chloroform or ether, the hip joint is powerfully flexed, after which the knee is forcibly extended, and then the ankle is brought into a condition of extreme flexion, and the entire limb should be maintained in this position for about 15 minutes, when a vigorous massage may be applied for 10 or 15 minutes more. Sometimes the limb is bandaged in this position, but, as a rule this is not advisable. The stretching may be repeated two or three times the patient being kept quiet in bed in the intervals. The writer has once seen an obstinate attack of sciatica speedily disappear in a patient who fell in such a position as to severely stretch the limb and nerve.

In the more radical method of stretching a nerve, the operation is performed, under chloroform, by cutting down upon the trunk and exposing the nerve sheath, after which the forefinger or a blunt hook is passed underneath it, and *steady traction* made for about 10 minutes, as the nerve is lifted from its bed and extended both in the proximal and distal directions. The wound is treated upon ordinary surgical principles, with strict antiseptic precautions, and rest of the limb upon a splint should be enforced for 10 days at least, till healing is firmly established. The ultimate result is often satisfactory especially when it is remembered that only the most obstinate cases are submitted to this method of treatment. According to Marshall, three out of every four cases so treated are permanently cured.

When stretching fails a similar incision may be made in the direction of the nerve trunk the sheath exposed, and the nerve divided after pulling it gently out of its bed.

In the more severe operation of neurectomy, undertaken after failure of division of the nerve, a portion of the length of the nerve is completely removed.

In avulsion, after anesthesia has been fully established, a free incision is to be made over the nerve near to its emergence from the bony canal or foramen through which it passes, and after its trunk has been fully exposed and freed from surrounding attachments as far as possible, it is seized between the blades of a stout pair of forceps, and forcibly torn out of its bony canal. Sometimes it may be even necessary to gouge out the bone surrounding the foramen in order to tear away as much of the nerve as possible lying in the canal.

The most formidable surgical procedures are generally necessary for the relief and cure of trigeminal neuralgia in its major form known as epileptiform neuralgia or *tic douloureux*; until the operation was perfected by Krause and Horsley this terrible malady was practically beyond relief.

Rose, after stretching the inferior dental nerve, was compelled

at a subsequent period to excise half an inch of it, and upon a second return of the neuralgia he repeated the operation, at the same time excising a portion of the lingual and upon a continuance of the neuralgia he removed the entire Gasserian ganglion and the superior maxilla. He recently states his belief in the superiority of the operation of removing large portions of the superior and inferior maxillary divisions of the nerve and leaving the ganglion alone. The removal of the Gasserian ganglion has been many times performed, and Krause has recorded a brilliant list of successes. He operates by the intracranial method, and removes the entire ganglion with its posterior root. He affirms that the operation is followed by remarkably slight disturbances, which are not to be compared with the terrible pains for the relief from which the operation is undertaken. Of 51 intracranial operations by different surgeons, 5 were fatal, and it is stated that no relapse has yet been reported. For the steps of Krause's heroic operation the reader is referred to the *Centralblatt für Chirurgie*, 27, 1895. Later figures given by Head show 42 operations without a death or relapse, and he states that we seem at last to have found a means of cure for the most terrible of all diseases. Recently Jaboulay has excised the superior cervical ganglion of the sympathetic for the relief of severe trifacial neuralgia of several years' duration. The operation gives relief by producing degeneration of the trifacial nerve of the side operated upon.

The method of treating neuralgia by hypnotic suggestion is mentioned last. The writer has had no experience whatever of its working, and though many reported cures are published the method has been condemned by those best qualified to speak upon its merits.

The treatment of the various forms of neuralgia—i.e., of neuralgia affecting the different nerves of the body—need not be gone over in detail, as the same principles are, for the most part, applicable to all nerves. Sciatica will be again briefly referred to under its own heading.

NEURASTHENIA—See Hysteria.

NEURITIS.

In every case a cause should be carefully searched for and if possible removed. Thus, if owing to syphilis or rheumatism, these diseases must be met by appropriate remedies. Iodide of Potassium, Mercury, or both combined, being indicated where there is any reason to suspect syphilis, and Salol, Salicylates and at a later stage Iodides, if there be any evidence of rheumatic inflammation, gout, and diphtheria. Tumours or foreign bodies, or inflammatory processes leading to purulent collections pressing upon and irritating the nerve in some part of its course, call for prompt and radical treatment. Where neuritis follows exposure

to the fumes or fine particles of irritant or other poisons as mercury inhaled for long periods, or the dust of arsenical papers, or lead poisoning, or chronic alcoholism, removal of the cause or removal of the patient from the sphere of its influence should be determined upon. Cold and damp may be the exciting cause.

Absolute rest of the affected limb, and all its muscles, with anodyne applications or deep injections of small doses of Cocaine or Morphia, and the general treatment applicable to the early stages of acute neuralgia are indicated. Leeching is of little use, but a few small cupping glasses placed over the leech bites may be productive of relief and may have the power of controlling the inflammatory action going on in the sheath of the nerve. *Cocaine* advises general or local sweating in cases caused by cold, and the local application of cold along the course of the nerve in traumatic cases, with hypodermic injections of morphia for spontaneous pain. He believes that cocaine injections not only relieve pain, but that they are curative. Blisters may be tried. Paralysis and wasting of muscles must be met at a later stage by the constant use of weak, continuous, and afterwards of an interrupted current electric massage, but these agents do harm in all acute cases.

Most cases of sciatica are examples of neuritis of the great sciatic nerve, and under Neuralgia and Sciatica its treatment is detailed, the various agents, constitutional and local, there mentioned, as well as the surgical procedures of nerve stretching, excision, &c., are for the most part applicable to neuritis of other nerve trunks.

In multiple peripheral neuritis the cause is always a chemical poison, or the toxins produced in diphtheria, syphilis, hepatitis, influenza, malaria, the different exanthemata, gonorrhoea, and rheumatism, erysipelas, &c. The commonest cause is alcohol. Next frequent is perhaps arsenic, then follow lead, mercury, ethyl, silver, bisulphide of carbon, &c.

In alcoholic neuritis, which may be taken as the type of the group, the first thing to do is to "stop the supply" immediately and completely, insist upon the patient going to bed and taking absolute rest. In bad cases a water bed is essential, and by it means recovery in otherwise almost hopeless cases may be often accomplished. The diet and general management will be the detailed under Alcoholism, and the chief difficulty will be experienced in combating the craving for the stimulant, the various aids in the struggle will be found upon page 27.

Local treatment must be of the most soothing in all varieties of peripheral neuritis, for the relief of pain warm fomentations may be resorted to once or twice a day, and after drying the limbs a generous layer of warmed absorbent wool should be applied, and the limb enveloped in thin Mackintosh or Oiled Silk, held in place by a light and evenly applied bandage. Immersion of the affected limbs, or even of the entire body in warm or hot water for con-

considerable periods often affords great relief. Everything that increases pain is almost certain to do harm, and hence the importance of absolute rest, as movement is always painful. The patient should be guarded carefully against all changes of temperature, whilst at the same time he should have abundance of fresh pure air and sunlight. There is no drug so valuable in the great majority of cases as small and frequently repeated doses of Antipyrine (2 grs. 4 times a day), and this can be combined with 20 minim doses of Ext. Cocæ Liq. Phenacetin and the other analgesics may be tried where antipyrine for any reason is not well tolerated. Most authorities prefer Salicylate of Soda; both drugs may be given in short alternating courses. Iodides are also frequently recommended. Arsenic should never be given. The recent appalling loss of life from arsenical beer drinking affords an illustration on a colossal scale of multiple neuritis, the result of the action of two distinct poisons acting together at the same time. Strychnine is also always harmful in the early stages of the disease. Morphia hypodermically may be called for in very severe cases. After the subsidence of pain and after prolonged rest of the affected parts, gentle passive movements for brief periods with massage should be warily attempted; as a rule these are too long delayed. At a later stage thorough massage, electricity both continuous and Faradic, and Schott or Swedish movements should be persisted in, and if the wasted muscles are slow to respond, small hypodermics or deep parenchymatous injections of Strychnine may be tried. (See also under Plumbism, Diphtheria, &c.)

NEUROMA.

Though much temporary relief may be obtained by the judicious use of pain-relieving remedies, as detailed under the local treatment of Neuralgia, permanent benefit must only be expected from cutting down upon the tumour and dissecting it out. Where it is found to involve the entire thickness of the nerve trunk, this should first be well stretched before excising the diseased portion, in order that the cut ends may be brought together by sutures before closing up the wound.

Mayo Robson after excising a considerable length of the median nerve, which was involved in a tumour to which it was adherent, transplanted a piece taken from the posterior tibial nerve, dissected out of a limb which had been amputated immediately before the neurectomy operation. The graft was retained in position by catgut sutures passed through its extremities. At the end of five weeks sensation in the parts below the operation was perfectly restored, though some atrophy of the muscles supplying the thumb remained. Notwithstanding that there is room for questioning this result as being one of genuine nerve-grafting, it clearly points to the treatment which should be adopted (when

possible) after the removal of a large piece of a nerve in its entire thickness in the operation for a neuroma.

Another plan has been suggested and carried out—viz., that of suturing the distal end of the divided nerve to the trunk of an large healthy nerve in the neighbourhood of the incision.

NIGHTMARE.

The treatment, if possible, should be preventive, and a close scrutiny of the causes which were at work in former attacks will generally give the clue to the management of the patient's feeding, sleeping, or mental work, which will prevent the recurrence of the disorder. As a rule, it is produced by the presence of a considerable amount of undigested or indigestible food lying in the stomach, and this is very often produced by late suppers in those who dine early. The habit of occupying the mind by severe exercise up to the moment of lying down may be the cause of the attack. Severe business worry, prolonged grief or anxiety, and alcoholic excesses may be the cause. Some patients are liable to experience attacks when they turn over upon their back in sleep, or when the weight of the body, sinking gradually into the depths of a soft feather bed, causes the head to slip off the pillow. Late dinners, which do away with the necessity for supper, a hard hair mattress, and a contrivance which awakes the patient the instant that he turns over upon his back, such as the tying of an empty cotton-wool bag across the back (i.e., over the spine), and the avoidance of indulging in severe mental labour before retiring to bed, will generally prevent the attack. A full dose of Bromide of Potassium or better still Paraldehyde or Sulphonal will be worth trying when there are special reasons for suspecting an attack.

When the attack comes on, the sooner the patient gets roused thoroughly the better. There is not much use in prescribing remedies which he is to use himself, as by the time he would be in a position to employ them the attack would have entirely passed away. He should be advised to get rapidly out of bed as soon as he is able, and dash some cold water upon his face, or dip his head into a basin of water. When the attack tends to recur upon the patient's again lying down, he may induce vomiting, and ensure the complete evacuation of the contents of the stomach. The friends of a patient who is subject to attacks of nightmare may be instructed to administer a whiff of Nitrite of Amyl, strong Ammonia, or a cold douche.

NIGHT SWEATS—See under Phthisis.

NIGHT TERRORS.

The distressing attacks occurring in young children appear to closely resemble nightmare in the adult. Their cause is often obscure. Sometimes they are associated with delayed dentition.

worms, and indigestion, but often appear to come on in otherwise healthy children, whose active little brains lead them into vivid dreaming. Where a cause can be determined of course its speedy removal is the first duty of the physician, who should minutely examine into the patient's condition especially with regard to the existence of epilepsy, and every departure from health should be remedied. The moral surroundings of children so affected should be closely studied. The ghost stories and appalling tales of the nursery, often combined with threats of boding evil and future punishment, should be discountenanced. Overwork at school and cramming must be strictly forbidden.

Sensitive or neurotic children who dread the darkness are sometimes injured for life by being shut up in dark rooms as a punishment for some trivial offence. A night-light in the bedroom often acts like magic in preventing attacks, especially in those cases caused by punishment in the dark lock-up.

E. G. Little has recently pointed out the close connection between this condition and dyspnoea, caused by valvular heart affection and obstruction of the posterior nares. Rey reports that he has seen complete cessation of night terrors after removal of adenoid growths in thirty-two cases.

Dyspepsia should be met by a powder after each meal, containing a few grains of Bicarbonate of Soda and a small dose of powdered Rhubarb.

Smith lays stress upon the importance of forbidding potatoes, puddings, fruit, and cake.

After correcting every probable or possible cause, the physician may think of administering drugs, with the view of preventing future attacks. This is the only available method in those idiopathic cases arising from some cerebral or centric cause of hereditary nature.

Bromides of Potassium, Sodium and Ammonium afford the best means of accomplishing this. One good dose, according to the age of the child, may be given at bed-time. Sulphonal or Chloral may be also given. The latter drug is, however, not so suitable, as patients often dream unpleasantly under its influence. For this reason Opium is also unsuitable. Paraldehyde is very efficacious, and Claus claims that Trional is curative. Generally it will be found only necessary to administer these drugs for one or two weeks at a time. The attacks tend to disappear naturally about the tenth or twelfth year.

If seen during the attack, little can be done save by soothing the patient's excitement and calming his fears, by assuring him of his present safety, though often this will be of little use, as there appear to be delusions and hallucinations which will not quite leave the patient till after he falls asleep again. Punishment, cold douches, or any treatment which could possibly add to the little patient's distress is to be strongly condemned.

The following mixture may be administered at bed-time every night to a child two years old —

R. *Ammonii Bromidi*
Sodii Bromidi ana ʒj.
Vini Antimonialis ʒss.
Syrupi Simplicis ʒj.
Aque Menthe Pip. ad ʒiv. *misce.*

Susnal cochlearum minimum omni nocte hora somni

Money recommends the following for excitable or nervous children. It may be given to a child seven years old :—

R. *Ammonii Bromidi* ʒj.
Pulveris Rhei gr. xlv.
Sodii Bicarbonatis ʒiss.
Syrupi Zingiberis ʒvj.
Aque Menthe Piperita ad ʒiv. *misce*

Fiat mistura. Capiat coch. med. ter in die post cibos, p. p.

NIPPLES, Sore.

Much of the misery attending first confinements may be attributed to trouble starting in the nipple during pregnancy. It may often be prevented by early attention and absolute cleanliness as the thick epithelial crusts should be regularly washed away, so as to cause the epithelial covering of the nipple to attain a sufficiently robust growth, otherwise it remains delicate and liable to tear fissure, or ulcerate. Mischief is done by the application of strong astringent applications at this stage. Such measures by hardening or partially tanning the skin, cause it to crack when traction is afterwards made upon it. The most that should be done in this way is occasional sponging with weak Spirit of Wine. Continual moist applications produce a sodden condition in which linear ulceration is apt to be set up. Glycerin, vaseline or ointments are also objectionable. Pinard advises strong solution of Boric Acid to be kept to the nipple, and Lepage's plan is said to have greatly diminished the frequency of abscess of the breast. He washes the nipples with the following solution — Red Iodide of Mercury 1 gr., Spirit 4 drs., Glycerin 4 oz., Water to 10 oz. If cracks are present they rapidly heal. When tenderness is felt in the nipples during pregnancy they should be protected from the friction and pressure of the dress by the constant use of a proper vulcanite or soft metal nipple shield.

Depression of the nipple, in which it lies in a hollow, projecting above the surrounding skin so slightly as to render it impossible for the child to grasp it, is a common condition, and if discovered sufficiently early may to a great extent be remedied by wearing all through the later months of pregnancy a properly fitting shield, made of soft metal. This shield should be of the form and proportions of a large nipple, with a wide base to rest upon the areola. It is known as the Wansbrough metallic shield, and is of the greatest value in this and many other conditions. Apparently some action is set up between the skin and the metal which becomes moistened with perspiration, and in the case of ulceration this has sometimes a very beneficial effect upon healing. For our present purpose it is only the mechanical effect of the nipple being driven slightly into the hollow cone of the shield by the pressure of the dress that is desired, so as to counteract depression. India-rubber shields are also useful. Where this plan fails there is little use in drawing out the nipples by means of any of the innumerable suction toys designed for this purpose, they often do mischief.

Kelner has devised a simple operation, by which the depressed nipple is raised out of the hollow, saucer-shaped depression in which it lies. He excises a ring, or two crescentic pieces of skin surrounding the nipple. As the wound heals, the approximation of its lips pulls upon the skin immediately surrounding the nipple, and causes it to project.

Trouble being anticipated, owing to the faulty formation or tenderness of the nipples, extra care should be taken immediately after delivery, as fissures in this locality are the chief cause of suppurating of the mammary gland. Two extremes must be guarded against—the child should not be permitted to tug away for any length of time at the empty breasts before milk has come to them, nor should it be kept from the nipple till the gland has become so engorged with milk that emptying of it is rendered most difficult and painful.

If, notwithstanding these precautions, the nipple becomes tender and painful, a glass nipple shield, to which an India-rubber teat is directly fitted on, may be applied to the tender nipple. Through the teat the child may be able to empty the breast without causing much pain to the mother.

This often proves unsatisfactory, and causes even more pain than the lips of the child directly applied to the nipple, and the physician has his patience sorely taxed by trying one form of breast-exhauster, nipple shield, and suction apparatus after another. In the meantime the soreness of the nipple increases, and is found to be caused by an ulcer, fissure, crack, or abrasion which demands local treatment.

The best lotion for general use is the following. The writer finds it much more likely to be successful in causing rapid healing than any other:—

R *Acidi Boracici* ʒi.
 Spiritus Vini Rectif. ʒi
 Aque Rose ʒiii *misce.*

Fuit lotio. M d n.

This should be sponged freely over the nipple and areola after each occasion when the child attempts to drink, and a small circular piece of lint soaked in it should be laid upon the excoriated surface, and covered carefully over with a larger piece of dry silk.

Some authorities recommend that the fissure or ulcer should be touched with a finely-pointed pencil of Nitrate of Silver. This is often a very painful practice, and the writer thinks that he has seen it determine suppuration. He has obtained more satisfactory results by touching the dried surface of the excoriation with strong liquefied Carbolic Acid before applying the above lotion. Carbolic Lotion (1 in 30) makes an excellent application, and sometimes eases the pain of the fissure by acting as a local anæsthetic, though the writer believes that healing is more rapid under the spirit and rose water.

Nearly every known form of astringent application has been recommended and used for the healing of sore nipples, and each nurse and physician believes in some one formula. As a rule it may be said that all ointments and greasy applications are found by experience to be much less satisfactory than lotions. Of ointments the best is Ichthyol 1 dr. to Lanoline 1 oz.

Astringents are open to the objection that by hardening the tissues they sometimes appear to increase the tendency to cracking and fissuring. The best pure astringent application is an infusion of Green Tea. If used at the proper time it often gives excellent results. Glycerin of Tannin is convenient, and is not open to the imputation of markedly increasing the tendency to crack or fissure.

Tannin may also be applied in watery or spirituous solutions.

Catechu, Rhatany, Kino, and other vegetable astringents have been used. Various Iron and Lead Salts are also much praised.

Substances in the form of fine powder may be used with advantage in the early stages, and when there is any tendency to eczema they are very soothing. In this way, with a puff Zinc Oxide, Fuller's Earth, powdered Starch, &c., may be applied. Glycerin of Starch has similar action. Lime water, Balsams of Peru and Tolu, Chlorate of Potash, Friar's Balsam, Collodion, Creolin 2 per cent, Egg Albumin, weak Sublimate Solutions, and many other plans might be mentioned.

The Glycerin of Borax must not be omitted. The writer has often managed cases all through the different stages with this treatment alone. Where for any reason the spirit and rose water lotion

should not be used, this is the application which he would select for routine treatment.

During the healing of the excoriations the best must be done to give the nipple rest by the use of pumps and shields, one after another of which should be tried till the least painful method of emptying the breast is arrived at. In very severe cases suckling must be suspended for a time, or even permanently, and in any case the supply of milk should be diminished, if abundant, by the judicious use of purgatives and alterations in the diet of the patient. The child's mouth should be kept healthy by constant cleanliness, and the occasional application of the Glycerin of Borax to the tongue and lips. (See also under Mammary Gland, Inflammation of, page 549.)

NIPPLE, Malignant Disease of.

Can only be met by the removal of the gland in young or middle-aged subjects. In aged patients the nipple may be removed with the surrounding tissue but this is not an operation likely to be followed by satisfactory results. The writer had under observation a typical case of carcinoma, following eczema of the nipple (Sir James Paget's Nipple), and the progress was so very slow, extending over many years, that operative interference did not appear to be warranted; death ultimately occurred from other causes.

Eczema of the nipple occurs as in other regions, and proves often susceptible to ordinary treatment, such as astringent lotions, the best of which would be strong solution of Subacetate of Lead 1, Liquor Carbonis Deterg. 1, Water 20. Ointments are more convenient, the most useful combination being Zinc Ointment 7, Liquor Carbonis Deterg. 1, Ammoniated Mercury 1. Powders, such as Oxide of Zinc, Fuller's Earth, or Starch Powder may be used with advantage. (See Eczema.)

Of a different nature, however, is the inveterate chronic eczema first described by Paget, which, confining itself for many months or even years to the nipple and areola, gradually and almost imperceptibly passes into a truly malignant form of disease, invading the deeper portions of the gland. For the latter condition, as already mentioned, there is no remedy but removal of the entire breast, and even this is far from being followed generally by satisfactory results. For the preliminary eczematous stage, little can be done. Most authorities regard it as beyond the reach of medicine. Certainly, irritating or stimulating applications should be forbidden, as by such means there is reason to believe the ultimate development of carcinoma may be hastened. The nipple should be carefully shielded from friction and the irritation liable to be produced by the pressure of the dress. A vulcanite or rubber shield answers this purpose well. Of local applications the best will be simple Vaseline or Elliott's Fuchsin Ointment (1 in 300), or a very weak Spirit Lotion, containing 1 grain of Corrosive

Sublimate to every 5 ozs. The writer would advise the alternate use of these applications for about one month at a time.

Recently Ethylate of Sodium Solution ($\frac{1}{2}$ B.P. strength) has been recommended.

NYMPHOMANIA.

The treatment of this affection when fully established cannot be carried out satisfactorily in institutions which possess a machinery necessary for the management of cases of insanity. Seldom in private practice can the serious responsibility of undertaking the moral, hygienic, and medicinal treatment of such cases be safely risked by the physician. As the nature of the affection is one which tempts the relatives of the patient to shun the exposure which they feel that removal to an asylum entails, the physician is often compelled to take charge of such cases for a time.

It is needless to dwell upon the question of moral treatment. This must be left in the hands of discreet and trusted female relatives or nurses. One thorough examination of the sexual organs should be made where there are reasons for suspecting local mischief. Frequent vaginal examinations must be strongly condemned, but as there may be possibly some serious local complaint it is advisable to have this set right when practicable. Ovarian neuralgia or inflammation, endometritis, congestion or chronic irritation of the external genital organs, may be the exciting cause of the mania. When such lesions are detected, and after from a serious consideration of the history and present condition of the patient, there appears to be a legitimate prospect of improvement after the local mischief has been removed, local treatment may have a fair trial.

Drugs alone are of little value, but as adjuncts to moral and hygienic management, Bromides, Camphor, and other anaphrodisiacs may be administered in full doses. Hypnotism has been tried and sometimes seems to control the affection for considerable periods.

OBESITY.

Of the various "systems" for the treatment of this condition some are based upon erroneous physiological theories, and serious injury to health and often death results from their routine practice. Some of the popular methods, whilst decidedly reducing the patient's weight may leave him in every other respect in a worse plight than before.

As a rule, it may be said that the treatment of obesity by the administration of drugs should be left out of the question. Occasionally drugs may be useful as adjuncts to other measures, but it used at all they must play a very subordinate part. If administered in such quantities as will ensure a marked reduction of body weight without the aid of radical changes in dietary, serious danger to life may result. The medicinal substances recommended for the treatment of obesity are—Vinegar, Alkalies, Chloride of Sodium, Bromides of Sodium and Ammonium, Salts of Potash as the Permanganate and Iodide, Liquor Potassæ, Vegetable Acids alone or in combination with Potash or Soda, *Fucus Vesiculosus*, and Thyroid Extract.

All of these, except perhaps *fucus vesiculosus*, are productive of serious mischief when given in doses sufficient to diminish the amount of fatty tissue, owing to their deleterious action upon the composition of the blood, when administered for long periods. Vinegar is often found to be the cause of serious mischief in vain females who imbibe it in large quantities with the intention of reducing their florid complexions and comely rotundities.

Fucus Vesiculosus, which is the basis of a popular remedy for obesity, is the ordinary bladder sea-weed or wrack. The writer has never had an opportunity of studying its action, but he knows that in some parts of the North of Ireland pigs have been fattened for market upon it, and it is therefore extremely improbable that in the ordinary doses recommended it can appreciably diminish the amount of fatty tissue in man, especially when we consider the close affinities existing between the two both structural, as observed in the dentition, and physiological, as seen in the omnivorous character of the food.

Thyroid Extract has lately been used for obesity, and many successes have been published. One tabloid, or $\frac{1}{4}$ part of a gland, may be given two or three times a day, and its effects closely watched. The reports are still very conflicting, but nearly all agree that it is a plan fraught with many serious dangers. Ebbstein condemns it strongly on the ground that it reduces weight by causing proteid-destruction, and not by simply reducing the amount of fat. If used at all it would appear from the researches of Schindler that very large amounts of proteid food must also be given. Bedard claims that arsenic prevents the thyroid from causing untoward results, but L. Mabile reports that when given in this way no loss of weight occurs.

Exercise is a powerful factor in the prevention of obesity, though not so reliable as a method for reducing it when once firmly established. No system of treatment will, however, be complete which does not recognise it as an important element, and little need be said here about it, since it will be referred to more fully in detailing Oertel's method. Exercise will, however, be of little avail in any case unless it be carried out in the open air. The writer believes that exercise systematically performed

Breakfa
kidney, ha

modification of Oerbi
verage at meals, all
space of two hours

The Salisbury method, which consists in using a diet consisting of beef steaks and hot water, has been modified by Towers-Smith, so as to free it from some of the serious objections to which it formerly was open.

The following is a sketch of his plan.—He gives for the first 14 days for breakfast and luncheon, 1 lb. of lean rump steak; for dinner, 1 lb. of grilled cod and 1 lb. of lean rump steak, and at intervals during the 24 hours, one gallon of hot water, and the last thing at night, half a wine-glassful of whiskey in cold water.

During the next 21 days the diet is more varied, and the hot water is reduced to 4 pints. Mutton chops without fat, turbot, whiting, sole, green vegetables, and rusks are allowed.

During the next 31 days the amount of hot water is further reduced to one quart, and tea is permitted with captain's biscuit, the bottom crust of a stale loaf, fish, fowl, game, joints of any kind, with a little light wine and seltzer water. 5 grains of Bicarbonate of Potash are to be taken night and morning. After these periods, which amount to about 9 weeks, the ordinary diet is indulged in.

The period is so short that there is not time for the loathing of animal food to become established. If it does threaten the beef may be prepared as beef tea or essence. The writer would still strongly object to this method, even for so short a period as 9 or 10 weeks, unless some fresh vegetables were allowed. He has seen such deplorable results where the plan was adopted, without the use of vegetables, for the cure of dyspepsia, that he believes it to be unwise to permit even this short period to be passed without fresh fruit and vegetables, and as far as he can see there is no reason why green vegetables should be withheld in the treatment of simple obesity.

This objection can be met in another way—*i.e.*, by infusing a slice or two of a fresh lemon in each cupful of hot water. In this way no serious deterioration of the blood can take place, and the objectionable taste of the hot water is entirely removed. The large quantities of hot water consumed in this system are of great value in flushing out all the effete products, and without this element the eating of 3 or 4 lbs. of lean meat daily might prove a serious risk to the integrity of the kidney.

Schroth's cure for obesity is founded upon the opposite principle to the Towers-Smith or Salisbury method, as he excludes, as far as possible, water or fluid in every form, hence this plan is often spoken of as the "Dry Cure." Dancel's method is almost identical with Schroth's. The diet consists chiefly of dry rolls, two or three days old, a little thick gruel, and a small amount of light wine. It is a method to which even the most resolute patients will not long submit. Moreover, where there is any gouty tendency along with the obesity, the dry cures, such as that just mentioned, and that of Schweninger's, already described as a modification of Oertel's, are dangerous as routine remedies for obesity.

Banting's Dietary.—Albuminous materials, 43 drachms, fat, 2 drachms, starchy hydrocarbons, 5.25 drachms.

Ebstein's Dietary.—Albuminous materials, 25.5 drachms; fat, 21.25 drachms; starchy hydrocarbons, 11.75 drachms.

If to these we add an estimate of the next method to be discussed—i.e., Oertel's—their relative values may be seen at a glance.

Oertel's Dietary.—Albuminous materials, 45 drachms; fat, 4 drachms; carbohydrates, 25 drachms.

Oertel's system of treating obesity, improperly called also Schweninger's, has already been detailed briefly when discussing the treatment of valvular lesions. Though introduced, in the first instance, to correct a condition of excessive corpulence, combined with great shortness of breath from fatty degeneration of the heart, it has been extended to the treatment of simple obesity and of valvular lesions.

It differs, as will be seen from the above figures, from the Banting system by permitting more fat and hydrocarbons, and from Ebstein's by nearly doubling the albuminates and carbohydrates, and halving the fat.

The chief feature in the method is the abstraction of water from the body. This is effected in reducing the supply to a minimum and increasing greatly its secretion and elimination by vigorous exercise, producing profuse sweating and also by the use of dry heat, as in the Turkish or hot air bath.

Upon page 393 will be found a diet table giving the particular composition of the different articles and the amounts in English weights and measures. This is the diet table recommended in the treatment of obesity associated with heart complications, but, as already pointed out, it is open to grave objections, and has been condemned by many leading authorities. It is, however, suitable in the management of simple obesity, the roast meat in the last meal of the day may be omitted. The details of the climbing and other exercises have been before referred to. In simple obesity without cardiac complications the amount of fluids may be gradually increased, and one or two glasses taken at the noon meal, and the amount of water increased from 2 to 10 oz. at the evening meal.

Schweninger's modification of Oertel's method consists in the absence of any beverage at meals, all the fluid permitted being swallowed after the lapse of two hours after each meal.

German See adopts Ebstein's method, only insisting upon copious imbibition of water or hot weak tea or coffee and abstinence from alcohol.

Weir Mitchell recommends the simple plan of feeding upon skimmed milk, with several ingenious restrictions. A modified plan has given good results, it consists in giving a tumblerful of milk and one egg every three hours, whilst awake, for 20 days at a time.

The Salisbury method, which consists in using a diet consisting of beef steaks and hot water, has been modified by Towers-Smith, so as to free it from some of the serious objections to which it formerly was open.

The following is a sketch of his plan:—He gives for the first 14 days for breakfast and luncheon, 1 lb. of lean rump steak, for dinner 1 lb. of grilled cod and 1 lb. of lean rump steak, and at intervals during the 24 hours, one gallon of hot water, and the last thing at night, half a wine-glassful of whiskey in cold water.

During the next 21 days the diet is more varied, and the hot water is reduced to 4 pints. Mutton chops without fat, turbot, whiting, sole, green vegetables, and rusks are allowed.

During the next 31 days the amount of hot water is further reduced to one quart, and tea is permitted with captain's biscuit, the bottom crust of a stale loaf, fish, fowl, game, joints of any kind, with a little light wine and seltzer water, 5 grains of Bicarbonate of Potash are to be taken night and morning. After these periods, which amount to about 9 weeks, the ordinary diet is indulged in.

The period is so short that there is not time for the loathing of animal food to become established. If it does threaten the beef may be prepared as beef tea or essence. The writer would still strongly object to this method, even for so short a period as 9 or 10 weeks, unless some fresh vegetables were allowed. He has seen such deplorable results where the plan was adopted, without the use of vegetables, for the cure of dyspepsia, that he believes it to be unwise to permit even this short period to be passed without fresh fruit and vegetables; and as far as he can see there is no reason why green vegetables should be withheld in the treatment of simple obesity.

This objection can be met in another way—*i.e.*, by infusing a slice or two of a fresh lemon in each cupful of hot water. In this way no serious deterioration of the blood can take place, and the objectionable taste of the hot water is entirely removed. The large quantities of hot water consumed in this system are of great value in flushing out all the effete products, and without this element the eating of 3 or 4 lbs. of lean meat daily might prove a serious risk to the integrity of the kidney.

Schroth's cure for obesity is founded upon the opposite principle to the Towers-Smith or Salisbury method, as he excludes, as far as possible, water or fluid in every form, hence this plan is often spoken of as the 'Dry Cure.' Dancel's method is almost identical with Schroth's. The diet consists chiefly of dry rolls, two or three days old, a little thick gruel, and a small amount of light wine. It is a method to which even the most resolute patients will not long submit. Moreover, where there is any gouty tendency along with the obesity, the dry cures, such as that just mentioned, and that of Schweninger's, already described as a modification of Oertel's, are dangerous as routine remedies for obesity.

Wood quotes the following dietary from an anonymous English military writer, who reduced his weight 117 lbs (more than 100) in 10 months by it:—

"6 a.m.—One pint of black coffee and one ounce of coarse brown bread or biscuit.

"9 a.m.—Four ounces of lean meat, three ounces of brown bread or biscuit, and half a pint of coffee.

"2 p.m.—Six ounces of lean meat, three ounces of brown bread or biscuit, six ounces of green vegetables, and half a pint of any fluid except ale, effervescing wines or aerated water, followed by half a pint of coffee.

"6 p.m.—Half a pint of coffee.

"9 p.m.—Two ounces of brown bread or biscuit and a couple of glasses of sherry or claret.

"Fruit *ad libitum* and liquorice powder *pro re nata*."

The different spare dietaries adopted at the various spas such as Carlsbad, Kissingen, Homburg, Tarasp, Enns, or Marienbad are often very successful in mild cases. Carlsbad upon the whole gives the best results.

Yeo's method may be given in his own words:—"The two principle objects of all these methods are first to make the corpulent person consume the excess of fat deposited in his body, by restricting the food supply or augmenting its combustion by increased physical exercise or other means, and secondly, to establish a dietary which shall prevent its reaccumulation.

"None of the methods described are appropriate to the treatment of all cases of obesity indiscriminately, while any one of them may prove successful in suitable instances. In conclusion, the following is the method which we recommend to be generally adopted. A very careful examination should be made of each case, in order to ascertain the presence or absence of any organic disease especially of any cardiac degeneration, and if we are satisfied that the obesity is not secondary to any other morbid state, or associated with any general degeneration of organs, we may proceed with confidence to prescribe an appropriate *régime*.

"The albuminates in the form of animal food should be strictly limited. Farinaceous and all starchy foods should be reduced to a minimum. Sugar should be entirely prohibited. A moderate amount of fats, for the reasons given by Ebstein, should be allowed.

"Only a small quantity of fluid should be permitted, but enough should be allowed to aid in the solution and digestion of the food.

"Hot water or warm aromatic beverages may be taken freely between meals, or at the end of the digestive process, especially in gouty cases, on account of their eliminative action.

"No beer, porter, or sweet wines of any kind are to be taken and no spirits, except in very small quantity. It should be generally recognised that the use of alcohol is one of the most common provocatives of obesity. A little Hock, still Moselle or light Claret, with some alkaline table-water, is all that should be

allowed. The beneficial effects of such a diet will be aided by abundant exercise on foot, and by the free use of saline purgatives, so that we may ensure a complete daily unloading of the intestinal canal.

"Of animal foods, all kinds of lean meat may be taken—poultry, game, fish (eels, salmon, and mackerel are best avoided), eggs.

"Meat should not be taken more than once a day, and not more than 6 ozs. cooked meat at a time. Two lightly-boiled or poached eggs may be taken at one or other meal, or a little grilled fish.

"Bread should be toasted in thin slices and completely—not browned on the surface merely. Hard captain's biscuits may also be taken.

"Soups should be avoided, except a few table-spoonfuls of clear soup. Milk should be avoided, unless skimmed and taken as the chief article of diet. All milk and farinaceous puddings and pastry of all kinds are forbidden. Fresh vegetables and fruits are permitted.

"It is important to bear in mind that the actual quantity of food permitted must have a due relation to the physical development of the individual, and that what would be adequate in one case might be altogether inadequate in the case of another person of larger physique.

The writer has quoted these observations at length because they embody his own views, and are opposed to the questionable practice of accepting some one of the so-called "cures" and adhering to it in every case with slavish accuracy, often to the danger of the patient's life or health. The above plan can be fully carried out without preventing the patient attending to his business, it tends to produce no unhealthy craving, and it may be safely persisted in for long periods—three essential conditions insisted upon by Ebstein. If a residence by the sea be available, and if sea-bathing and swimming exercises be indulged in, the best possible results are obtainable.

CEDEMA—See under *Bright's Disease, Heart Disease, &c.*

ŒSOPHAGUS, Foreign Bodies in.

Fish-bones and pins are perhaps the most frequently-found impacted substances; artificial teeth, coins, and morsels of bolted food are not rare.

For small objects, as pins and fish-bones, the expanding horse-hair probang should be gently coaxed past the foreign body for several inches, when, by expanding the hair portion and keeping it open as it is being withdrawn, the bone or pin will be brought up by gentle manipulation. In the same way coins may be extracted by the money probang or coin-catcher. In the absence of a suitable probang, a skein of thread attached to the end of a flexible bougie, as recommended by Davies Colley, makes a

suitable substitute, in which the body may be entangled as it is withdrawn.

Crégny advises in such cases that a skein of thread rolled up in a globular form, to which a piece of stout ligature silk is attached should be swallowed in jam or butter, and after the foreign body has been passed the thread may be pulled up by dragging upon the silk. As it is withdrawn, the foreign body may be found entangled in its meshes. Swallowing a large bolus of bread may carry small fish-bones and bristles before it into the stomach. Where the foreign body is soft it may be gently pushed down by the pointer the probang or by the tube of the stomach pump until it enters the stomach. Where angular hard bodies are impacted this is generally a dangerous practice, and a pair of long curved forceps should be employed. If high up in the œsophagus or pharynx they may be seized by the surgeon's fingers.

Occasionally the act of vomiting may be made to dislodge impactions. This may be induced by tickling the fauces or by giving Apomorphine ($\frac{1}{2}$ gr.) hypodermically. It is not, however, a safe practice when the body is of sufficient dimensions to completely block up the tube, as a rupture below it might possibly take place.

A smart slap with the open hand, applied between the shoulders, is a popular, safe, and sometimes successful procedure when the body is lodged high up.

When a hard angular body is pushed down into the stomach the efforts used for its removal purgatives should not be administered, but firm pultaceous food or dry biscuits may be given with the view of enveloping the object and shielding the intestinal and gastric walls from its angularities. A diet of hard-boiled eggs is, in the writer's opinion, the best means of carrying out this object.

X Rays afford invaluable aid in localising the position of the foreign body, when it is a coin or other hard substance. Under such circumstances, a radiograph should if possible be obtained.

Where a large or angular body is impacted in the upper part of the tube laryngotomy or even tracheotomy may be necessary to prevent suffocation in the presence of severe dyspnoea, and even artificial respiration may be necessary till the body is extracted. Such cases are, however, fortunately rare.

Jones argues against forcible efforts at removal through the mouth, and urges early resort to œsophagotomy where reasonable attempts prove unsuccessful.

Where angular and unyielding bodies, like false teeth and their accompanying fixings, become firmly impacted there is nothing left for the surgeon but to perform œsophagotomy by opening the tube through a skin incision four inches long made along the anterior border of the left sterno-mastoid muscle. The tube is reached by retracting the carotid sheath, sterno-mastoid and omohyoid muscles outwards and the trachea inwards. It is

opened over a pair of long curved forceps introduced through the mouth and made to bulge into the wound through the opening. The foreign body is to be extracted with great gentleness, and the wound in the tube closed with catgut sutures. The skin wound and the after-treatment are to be carried out upon ordinary surgical principles.

Cases are recorded in which artificial teeth with their hooked plates had been swallowed and passed into the stomach, where they have given rise to severe pains and obstinate vomiting; they have been successfully extracted after having been fished up with a money probang or coin-catcher introduced through the mouth. Where this fails the foreign body may be removed from below through an opening made into the stomach.

For foreign bodies in larynx, trachea, and bronchi, see under Air Passages, page 25.

ŒSOPHAGUS, Stricture of.

Practically, these are found to be simple—the result of corrosive poisons—or malignant. Hysterical stricture rarely requires treatment. When it does, the passage of a large bougie, with the administration of agents mentioned under Hysteria, speedily effects a cure.

The treatment of simple stricture is for the most part embraced in the word dilatation. When a bougie can be passed, it should be kept in as long as the patient can tolerate it, after which a larger one may be tried, and so on till the canal is fully dilated. After corrosive poisoning, of course, the passage of instruments is unjustifiable until healing of the ulcerated spots has taken place, but it is a mistake to delay the introduction of a bougie too long. In severe cases stricture is almost certain to occur and if left to itself the canal or tube may become entirely stenosed at some point or points in its course, hence the necessity of watching such cases and insisting upon the passage of the largest possible bougie from time to time, as long as any narrowing is found to remain. The writer objects to the ordinary olive-shaped bougie, mounted upon the whale-bone stem. He believes a well-made gum-elastic solid instrument is a safer dilating force, and he has had such made with a considerable taper at the point.

The graduation in size may in the smaller ones reach from about the calibre of a No 4 English catheter at the point to a No 8 or 9 a few inches upwards. For long strictures these answer very well. In the *Dublin Journal*, August, 1879 he reported a case which he exhibited before the Ulster Medical Society, in which the smallest catheter at one time could not be made to pass. Nearly every form of dilator was tried, and, finally, he used a bougie made of fresh sea tangle partially dried with success. This substance was soft enough to work its way through the narrow ulcerated opening without causing pain, and yet possessed sufficient firmness to become the medium of conveying a safe

amount of force. In addition to these qualities, there was, of course, the valuable property of its trifling increase in size, as it lay in the narrow stricture. After a time, large graduated gum-elastic bougies were introduced, and the patient made an excellent recovery.

Where a gum-elastic tube can be passed through the stricture it may be left *in situ* for several days with the greatest advantage.

Internal œsophagotomy is a dangerous operation, and in the skilful use of graduated bougies it is uncalled for.

The stomach has been opened by Loretta, and through a metallic dilator has been successfully employed to dilate a stricture situated near to the cardiac end of the œsophagus, after which the gastric incision has been sutured and the stomach returned to the abdominal cavity and the skin wound closed up.

Where the passage of even the smallest bougie is found to be impossible, gastrostomy or œsophagostomy will be the only resort left to the surgeon.

Carter records an operation by Bernays for an occluded œsophagus of five years' standing. Gastrostomy had been performed four years previously, and the patient was living on nourishment injected through the fistula. He cut down upon the site of the stricture at the inner edge of the sterno-mastoid, and opened the gullet above the stricture. Later on he perforated the stricture, and a pointed bougie introduced from below through the gastric fistula, and eventually inserted a Renver's funnel, through which the patient was able to swallow food, which entered the stomach for the first time in five years by the natural route.

The treatment of malignant stricture of the œsophagus is unfortunately much less satisfactory; at best it can only hope for palliative.

There is considerable difference of opinion regarding the advisability of dilating a malignant stricture. Though the author has satisfied himself that by the judicious and gentle passage of a solid graduated gum-elastic instrument he has been able to prolong life and relieve suffering, he does not intend to resort to the method again. Recently in one of his hospital cases in which a bougie had never been passed, the patient was awaiting the insertion of a Symonds' tube, when suddenly while sitting in the ward an enormous gush of blood came from his mouth, and he speedily sank. The post-mortem revealed a malignant ulcer which had perforated the aorta; the stomach and intestines were filled with blood.

When the passage of liquids becomes difficult there is nothing to be gained by the introduction of the bougie. Two courses then open, either to introduce a soft rubber tube through the mouth or nose into the stomach for feeding purposes, and allow it to remain as long as the patient can tolerate its presence, or to adopt Symonds' ingenious plan. He inserts into the stricture upon the end of a suitable bougie passed through the most

short gum-elastic tube, with the upper end dilated into a flattened funnel. This upper end rests in the dilated part of the œsophagus immediately above the stricture, whilst the tube occupies the stricture, and extends below it. A piece of stout silk is attached to the funnel-shaped part, and is brought out through some gap in the teeth, and fastened to the ear, or in any safe and convenient way. The tube may be left *in situ* for weeks. Through it, liquid food passes easily down to the stomach, and often after a time a larger and shorter tube may be inserted when dilatation has resulted from its pressure.

When the stricture is high up the rigid tubes are not well borne. Symonds then employs a long, soft rubber tube introduced through the stricture and left *in situ*, the end of the tube being fixed to one of the molar teeth or actually protruding through the mouth, and secured around the ear, or wherever may be most convenient.

When, through frequent spasmodic cough, the tube can be no longer kept in its place, and the stricture gradually closes, and in those cases where, owing to the narrowness of the stricture, tubage is, from the first time that the patient has come under notice, impossible, gastrostomy or œsophagostomy is the only means by which the surgeon can hope to prolong life or minimise the terrible sufferings attending slow death from starvation.

Rectal feeding should be tried in all cases, even where the patient is still able to swallow liquids. (See also under Cancer, page 117.)

ONYCHRIA.

The old-fashioned treatment is still employed by some surgeons. It consisted in the local application of Abernethy's Lotion which is composed of 2 drachms of Liquor Potassæ Arsenitis and 1 oz. distilled water. This was applied upon lint, which was frequently moistened by fresh quantities of the arsenical solution. This method sometimes increases the pain and tension of the inflamed tissues. A better application is the Carbolic or Spirit Lotion.

Carbolic Acid (1 drachm) and water (4 oz.) make a soothing antiseptic lotion, which, being poured upon lint, may be wrapped round the last joint of the finger, and enveloped in oiled silk, which should be firmly tied at its distal end, so as to form a perfectly impervious finger-stall. The anæsthetic influence of the acid is most grateful, and after a time the ulcerated surface ceases to occasion pain, and healing is induced. Chloral (5 to 10 grs. to 1 oz. water) may be also used. Iodoform may be dusted over the part, or a mixture of Iodoform and prepared Calamine in equal quantities may be employed.

Finely powdered Nitrate of Lead is an excellent remedy, and the writer has used it successfully in the troublesome onychia attacking the toes of the young girls employed in the moistened atmosphere of flax-spinning rooms.

Where an ointment is more convenient, the Boracic Acid or Mercurial, or Red Precipitate Salve may be used.

Sometimes a free application of a strong solution of Nitrate of Silver at the beginning of the affection leads to a good improvement.

Where exuberant granulations spring up, strong Carbolic Acid or the Liquor Ferri Perchlor. Fort., or the Liquor Ferri Persulf. may be brushed over them, or Tannin or Alum may be dusted on the part, or it may be daily rubbed with a large crystal of Superoxide of Copper.

Where these measures fail, the nail should be removed and the raw matrix dressed with the powdered Nitrate of Lead.

In very obstinate cases, where the onychia returns with the growth of the new nail the best procedure is to shave clean with a sharp large scalpel the dorsal surface of the last phalanx removing both nail and soft parts, or to remove the nail and destroy the matrix with strong Carbolic or Nitric Acid, or with a strong solution of Pernitrate of Mercury.

Syphilitic onychia is best treated by the application of a weak Corrosive Sublimate Lotion, Yellow or Black Wash, or by dusting over the part with Calomel, or by applying Cantharid Ointment spread upon lint.

In such cases internal antisyphilitic medicines are absolutely necessary, and in strumous subjects constitutional treatment is equally necessary.

OPHTHALMIA—See Conjunctivitis.

OPIUM HABIT (Morphinism).

The management of cases is very difficult where, from the prolonged indulgence in Opium or Morphia, generally commenced in the first instance, for the relief of pain the patient becomes enslaved to its use that a confirmed habit becomes established.

The habit may remain long after the cause for which the narcotic was first prescribed has passed away. Not uncommonly the administration of morphia by the hypodermic syringe is the form in which the vice is indulged.

In whatever way the narcotic has been used, when an effort comes to be made by the patient to break through the chain which has enslaved him the physician will have to decide the serious question of whether the habit should be broken off suddenly or gradually.

The former plan is the best in those cases where the habit has not been long established and where the dose has been always small or moderate. It affords in all cases the best prospects of success when it can be carried out, though the sufferings of the patient are most terrible for a time, and liable to be followed by collapse.

The almost unanimous decision of those who have special experience in treating the worst forms of the confirmed morphia habit during late years is in favour of not a sudden but a rapid withdrawal, as practised by Mattison.

When such a course is decided upon, the patient should be under the eye of a physician all the time, and a thoroughly reliable and firm nurse is an essential part of the treatment.

Allbutt states that there is one means of dealing with morphinism, and one only—namely, seclusion in a special retreat, and submission to the discipline therein provided for such cases. Speaking of those who have taken large doses and are cachectic, he advises that half the usual quantity may be administered during the first twenty-four hours, halving this again and again; in five to seven days the dose may reach the vanishing point. The number of injections as well as the dose must be steadily diminished, reserving the largest dose for bed-time.

The great difficulty in this plan of rapidly stopping the narcotic is the effect upon sleep, and provision must be made for this from the first. Under insomnia, the reader will see all the various substances, any one of which he may try which does not contain opium or morphia. The writer has tried almost all of them in the condition under notice, and he finds that either Paraldehyde or Sulphonal is the best. It is a good plan to abstain from chloral and Indian hemp, as there is much danger of a habit being established by the use of these drugs, and the use of sulphonal and paraldehyde upon alternate nights is free from any objections. 765 gr. Hyoscine and Hydrate of Amylene (60 minims) have been strongly recommended.

Mattison gives gradually increasing doses of bromides till 90 grs. daily are taken, when the morphia is entirely stopped, after which 30 grs. Trional are given nightly for seven days, the dose being then diminished to 15 grs. nightly for another week, after which Paraldehyde and Chloral in small doses may be given. Macleod gives 2 drs. Sodium Bromide every two hours for two days, and 3 drs. during the third day. 3 oz. suffice, and the sleep lasts several days.

Various drugs have been recommended as substitutes for the opium during the day-time, but, speaking generally, there is little advantage in replacing one vice by another. The exception, which may be made in the case of alcohol, will be presently referred to, some authorities substitute Codeine.

Coca has been freely given, and the fluid extract of Erythroxylon Coca is a favourite remedy all through the depression period. The danger of the cocaine habit must not be forgotten, though it requires a longer period for its establishment than the time necessary to wean the patient suddenly from his opium or morphia vice. Tea-spoonful doses of the liquid extract may be commenced, and upon the second day, when the symptoms are at their worst, the dose may be given every hour. Obersteiner gives cocaine

under these circumstances in solution by the mouth, and the daily amount during the first two or three days is about 8 grains administered frequently in small quantities. After about the sixth day the drug should be stopped entirely. It is at the best a very doubtful and beguiling aid, and its use is condemned by those who are best qualified to judge.

Recently Ahlborn reports that he has successfully treated several cases by the aid of Heroin (Diacetyl-Morphine Hydrochloride). His plan is to stop the morphia immediately and to administer tablets of Heroin, $\frac{1}{2}$ gr each for every $\frac{1}{2}$ gr. morphia that the patient was in the habit of taking. Thus a patient who injects 12 grs morphia daily gets 2 grs heroin daily for about one month when the craving will generally be found to have disappeared. The heroin is then reduced to a half, and in another month to one-quarter this amount, and finally it is stopped entirely.

Other agents, such as Quinine, Antipyrine, Red Cinchona, Strychnine, &c., have been recommended, but beyond relieving some passing symptoms they are of little use. Diarrhoea, sickness, nausea, and other distressing signs are certain to aggravate the sleeplessness, and must be met by appropriate remedies.

The following mixture may be given every hour or every two hours.—

R. *Extracti Cinchonæ Liq.* ʒj.
 Extracti Coaræ Liq. ʒii.
 Tinct. Cinchonæ ʒii.
 Spiritus Ammoniar Aromat. ʒiiss.
 Tincturæ Digitalis ʒij. *misce.*

Fiat mist. Capiat coch. min. ex ʒij. aquæ secundis horis.

The diet should be carefully seen to. In the shock and depression caused by the sudden withdrawal of the drug, there is urgent necessity to get in all the nourishing food possible. Strong beef essences and concentrated soups, with peptonised milk and other liquid foods, should be given at the shortest possible intervals, and a stock of these should be laid in before beginning treatment. Flug emphasises the importance of preventing hyperacidity of the stomach, which increases the craving, and it is a wise plan to give 15 grs Sodæ Bicarb. and 1 or 2 grains Pepsin after each meal. The question of stimulants will crop up early, and where there are strong reasons against alcohol, Sal Volatile may be freely given in small quantities, and well diluted.

The depression is so terrible that the unfortunate victim, who has always got little foretastes of it during the temporary withdrawal of his drug upon previous occasions, refuses to submit to

treatment unless some plan is made clear to him that his sufferings shall be minimised.

The physician will often be tempted to yield to his solicitations, and give some opium during the period of terrible depression, and in many cases the treatment breaks down utterly, owing to the alarming condition of the patient upon the second or third morning, when it would appear that to continue the withholding of the drug would mean the cost of the patient's life or reason. Cardiac tonics are demanded at this stage.

The writer has devised a means which meets the difficulty, and which he has carried out satisfactorily in one case. It consists in putting the patient under the influence of Alcohol, which should be administered in such doses as will markedly influence the cerebrum, and keep the patient in a state of mild intoxication. The treatment may commence six or eight hours after stopping the opium, and it may be continued for four or five days, and may be gradually or suddenly stopped, as the symptoms indicate.

The writer is aware that such a practice is open to serious objections, the chief of which is the danger of replacing a serious vice by a worse one. It may be said, however, that three, four, or five days alcoholic excess is not likely to lead to the establishment of the alcoholic habit, nor is there any serious danger of delirium tremens following.

This treatment should only be attempted when the medical man can give the closest possible supervision to the case, and the patient must be carefully watched by a skilled nurse all through. It would appear to be most applicable to those apparently hopeless cases where the patient is anxious to try and rid himself of his enemy, where he has sufficient remnant of will left, and where all other means have been tried and failed.

The physician must ever remember, however, in dealing with patients who have become the victims of any craving or habit, that there is always a certain degree of moral perversion present, and that in some cases the vice may really be a symptom or result of some strain of insanity. In this latter case it is unjustifiable to adopt the alcoholic treatment unless the patient can always be kept under proper restraint. As a rule, in such cases, even though one vice is removed, the patient will, with his perverted moral sense, select another, and such cases are often found to be the victims of both opiates and alcoholic stimulants. If the physician should succeed in weaning them off their opium, he will probably find it will be only to receive the credit of having made them intemperate.

Where the gradual plan of treating the patient at home by steadily diminishing the dose of opium or morphia is tried, the diminution must be made by fractional increments. Failure generally results in chronic cases by the physician's haste or anxiety to make progress, and sometimes the patient is also to blame, being tempted to curtail to an extent beyond his power of

endurance. Moral treatment, in such instances, is of the greatest value for a time and every change in the patient's environment may be a benefit, such as the selection of new companions, occupation and change of scene and habits. Coca is here of decided value and it may with advantage be given in combination with small doses of antipyrine. Alcohol is especially dangerous, and on no account should chloral be prescribed. The greatest difficulty will be from insomnia, and Sulphonal combined with a diminished dose of the opiate at bed-time, is the best remedy. As Sulphonal is slow in acting, the writer has, in one bad case, obtained very satisfactory results in prescribing a dose of 45 grs. 30 or 45 minutes before retiring to rest, and then giving a small opiate just as the patient lies down. This prevents the critical period of unrest at the beginning of the night, which often is the precursor of intolerable insomnia. Paraldehyde often answers well in large doses (90 minims), as it then will induce a drowsy or dreamy quiet state, extending well on into the following day in which the craving for opiates may be weakened.

The plan of substituting Cannabis Indica or other narcotics occasionally may be tried, but generally it will not be found to do much good. Bromides in full doses always are helpful in quieting the unrest, though they often cause much depression.

Contrary to what he was led to expect the writer has seen success more frequently follow the gradual plan where the hypodermic method had been the form of the opium vice than where opiates had been taken by the mouth.

Oscar Jennings, in a very able article in the *Medical Annual*, insists upon the gradual plan being the best, and he places the average duration of treatment at one to three months, during which the patient may carry out his ordinary avocation if it admits of constant supervision. He takes the case of a patient injecting 20 grs. morphia daily. The syringe is given up, and an initial drop of 3 to 5 grs. is made, and a daily drop of 1 gr. for some days till this becomes irksome, then $\frac{1}{2}$, $\frac{1}{2}$, and finally $\frac{1}{4}$ gr. is daily dropped. The real difficulty begins when the daily amount injected is lessened to about 2 grs. After this period, for every sixth of a grain suppressed he gives twice as much by the mouth or rectum till in about 12 days the injections are reduced to zero, after which the dose by the mouth is gradually diminished to nothing, and if the "progression" is properly carried out the cure is effected with only a night or two of restlessness requiring hypnotics. No suffering need ever occur. Sparteine hypodermically or Digitalis by the mouth forms an essential part of the routine and must be commenced as soon as the heart becomes sluggish or feeble.

Hall used large doses of Sparteine as soon as the sphygmograph showed their necessity. He lays great stress upon the danger and frequency of relapses and upon the mistake of believing anything which a morphiomaniac states about his dose, &c.

Exercise, as cycling and baths (hot packs), are of great value in diminishing restlessness and *ennui*.

The physician who wishes to see the whole question of the morphia habit discussed as it has never been before is strongly recommended by the writer to read the article on Morphism, by Clifford Allbutt, in the second volume of his "System of Medicine," as in his opinion this constitutes one of the most brilliant chapters in the literature of medicine.

OPIUM POISONING—See Poisoning.

ORCHITIS AND EPIDIDYMITIS.

Rest in bed in the horizontal position, lying on the back, is to be prescribed when this is convenient. A small board should be placed across the front of the thighs; upon this the scrotum can be supported as if resting upon a shelf. A board about as thick as the sides of a cigar box, only longer, with the upper edge bevelled in the middle, where it may be hollowed out, so as to get well under the scrotum, answers the purpose. A piece of broad strapping may be used in the same way, but it soon becomes permeated with moisture.

Where the patient *must* move about, a different method of obtaining rest for the inflamed gland should be sought. Any of the ordinary suspensory bandages may be tried. As a rule they are much inferior for this purpose to one which the patient can extemporise for himself. This he does by tying a handkerchief bandage, or girdle round the waist, to which another handkerchief (three-cornered) is attached behind in the middle line, brought down between the thighs and fastened again in front to the waist girdle. In this way not only is efficient support given to the testicle, but whatever local application is selected it can thus be easily kept in contact with the scrotum, and at a later stage moderate continuous pressure may be kept up. Patients are found to devise various methods by which the suspension can be carried out by attaching the bandages to the braces or shoulders. At the onset, or as soon as the patient comes under notice, a smart Saline purgative should be given. One oz. Rochelle Salt in a bottle of aerated lemonade is an efficient and palatable dose. In very plethoric subjects Sulphate of Magnesia may be given often, in teaspoonful doses, so as to keep up brisk purging for a time.

Where there is much constitutional disturbance a diaphoretic and antiphlogistic mixture like the following may be given —

R. *Tinctura Veratri Vir.* ℥xvi
Liquor. Ammon. Acet. ℥ii
Vini Antimonialis ℥j.
Aqua Camphoræ ℥v *misce.*

Fiat mistura. Capiat cochlearium unum magnum secunda quaque hora.

Salicylate of Soda is perhaps the most valuable of all drugs for internal use. Salol has also been recommended, but is not so efficient as the salicylate.

In very severe cases the saline may be preceded by one large dose of Calomel, though there is generally little to be gained by this, as the saline acts more quickly. Pulsatilla is said to have a specific effect in orchitis. It may be combined with Aconite. The diet should consist of milk and kaffi water or whey, rice, and mucilaginous drinks, solids and animal food being forbidden. One large Opiate at night with Bromide of Potassium is a valuable method of giving ease and relieving pain. Local treatment is of importance. Where the patient is seen early a bladder of Ice or cold evaporating lotion continually changed is the best application. A cambric handkerchief, dipped in iced water with some pieces of ice laid in between its folds, is an efficient method of applying cold. Some surgeons employ a modification of Lister's tubes.

Janowski and others speak very highly of the local application of Guaiacol 5 per cent. to 10 per cent. in Vaseline. Under its use pain and tenderness rapidly subside, and the patient is comfortable in 20-30 minutes. The application requires to be repeated in 6-8 hours.

Where pain and tension are aggravated by continuous cold, warm Poppy Fomentations are grateful, and even Poultices, smeared over with the Extract of Belladonna, may be employed or Belladonna Extract and Glycerin may be painted over the scrotum. Where orchitis occurs as a complication of parotitis this will be the safest plan of treatment. Where epididymitis occurs as a sequel of gonorrhoea, injections of astringent or antiseptic solutions must be stopped, and though the rule is laid down that all urethral medication must be suspended, the writer has seen good results from steady perseverance with injections of warm water, sterilized by a few drops of Condy's Fluid.

Where there is great pain, swelling and tension, any of the following procedures may be adopted:—

1. The scrotum may be painted over with a solution of Nitrate of Silver (1 in 6).
2. Leeches may be applied to the neck of the tumour or to the groin.
3. Any of the large scrotal veins may be opened with a lancet.
4. Several short incisions may be made into the swollen or oedematous tissue of the scrotum.
5. A fine trochar may be driven into the cavity of the tunica vaginalis, and any hydrocele fluid permitted to escape.
6. A series of punctures with a stout needle or fine trochar may be made into the substance of the testicle or swollen epididymis.

7. Pressure may be applied to the swollen gland either by means of strapping or the pressure of an elastic bag or suitable bandage. These plans of making compression are at first very painful, but are said to be soon followed by marked relief.

Seldom will any of these procedures be required. The great majority of cases yield in periods varying from 48 hours to 6 or 8 days to the treatment first mentioned.

Collodion has been used as a mild method of causing compression, as it contracts after drying. Should signs of suppuration show themselves, a free incision into the fluctuating point should be made, and the wound treated by a weak Sublimite Solution or other antiseptic lotion, or dusted over with Iodoform.

Where there is much induration or thickness left after the subsidence of the inflammation, the Lin. Potassi Iod. C. Saponis is the best local application spread upon lint and applied to the scrotum. Over this by strapping or by means of a laced elastic bag, firm and steady pressure may be continuously kept up. Some surgeons prefer to use Mercurial Ointment, the Iodide Liniment often brings out an eruption. Iodide of Potassium should be given internally in these cases after the subsidence of the acute symptoms.

Orchitis, or epididymitis, following gouty inflammation of the urethra, yields to rest, warm fomentations or hot poultices, and the administration of full doses of Colchicum Wine combined with Salicylate of Soda and the occasional use of cathartic doses of Sulphate of Magnesia.

Chronic orchitis being in the great majority of instances a syphilitic affection, constitutional as well as local treatment will be required. The constitutional remedy is, of course, Mercury or Iodide of Potassium. There are few cases in which more marked evidence can be observed of the power possessed by these drugs in causing the absorption of inflammatory products.

The administration of mercury will be decided by the history of the case. In weak cachectic subjects who have suffered from syphilis for many years previous to the appearance of the orchitis, and who have been previously brought well under the influence of mercury at least once before, it will be wiser to begin with large doses—10 to 15 or even 25 grains of the iodide of potassium three times a day. In all other cases mercury may be given in amount and in the manner indicated by the symptoms and history of the case. Thus in comparatively recent cases the patient should be brought under the influence of the drug without unnecessary delay by inunction or by the administration of moderate doses of any mercurial preparation. (See under Syphilis.) It will never be necessary to cause salivation, but the drug should be pushed till the gums are slightly touched after which the effect may be kept up for long periods without injury to the patient till the induration in the testicle melts away.

In very chronic cases the iodide may be combined with mercury,

and the writer has obtained excellent results from Donovan's Solution :—

R. *Liq. Arseni et Hydrarg. lod. ʒiss.*
 Aqua Destillata ad ʒiv. misce.

Fiat mistura, cujus capiat drachmam mensurâ ex aqua vinario aquæ post cibos.

The perchloride of mercury may be given in a mixture with the iodide of potassium. The following is an efficacious combination in such cases :—

R. *Hydrargyri Perchloridi gr. iss*
 Potassii Iodidi ʒiij.
 Aqua Destillata ʒxij. misce

Fiat mistura. Sumat ʒss. ter in die post cibos ex aqua

The mercurial suppository is a favourite means of administering the drug with the older surgeons. The younger school resorted to fumigation or vaporization in the treatment of syphilitic orchitis.

Local treatment may be summed up in the words Pressure and Mercurial Ointment. Where hydrocele complicates the case a very common occurrence—time will be saved by first tapping the tunica vaginalis, and, after the evacuation of the fluid, applying lint smeared over with Ungt. Hydrarg., and then by means of strips of stout adhesive plaster, applying firm pressure to the swollen gland.

Where the system is already under the influence of mercury the mercurial dressing may be omitted and plain soap plaster applied direct to the shaven scrotum. This is often the only treatment necessary in dealing with a chronic orchitis which is not syphilitic, such as where considerable induration or enlargement follows the subsidence of an acute attack of orchitis or epididymitis or follows upon an injury.

Where the induration is localised in a portion of the epididymis or body of the testicle, or in those cases where pressure cannot be tolerated, a little mercurial ointment may be rubbed in with the finger.

In non-syphilitic cases the best remedy to employ is the Liniment of Iodide of Potassium with Soap. This may be firmly rubbed in with moderate pressure morning and night till the skin becomes tender. Iodine in the form of a liniment, consisting of equal parts of the B.P. Liniment and Tincture, may be applied with a brush daily; it often causes much irritation and sometimes oedema of the scrotum.

When pain or tenderness exists the mercurial preparation may be diluted with an equal amount of the Unguentum Conu, or 10 or 15 per cent. of the Green Extract of Belladonna may be combined with it. The Oleate of Mercury with Morphia may be employed with benefit.

The following may be tried :—

R. *Oleat Hydrargyri* ʒiij.
 Unguenti Conu ʒiv.
 Extracti Belladonnæ ʒi. *misce.*

Fiat Unguentum.

In malarial subjects Quinine should be given in large doses. In gouty orchitis of a chronic nature, Salicylate of Soda may be given in doses of 15 grains twice a day, and $\frac{1}{2}$ grain of the Extract of Colchicum may be administered at bed-time every night.

When the above treatment has been followed out for a few weeks the organ generally diminishes in size and in consistency, and the true testicular sensation returns. Rarely will castration be called for, unless in neglected cases where the surgeon may find the testicle hopelessly destroyed by abscesses or softened gummata. During the treatment by mercurials and pressure the patient can generally be permitted to walk about or pursue his usual avocation, all sexual exercises being strictly forbidden.

Close attention to diet, and to every means by which the general health can be improved must not be neglected, and at a later stage Cod Liver Oil, tonics, Chloride of Gold or Arsenic and Strychnine in combination with Iron, and sea bathing will be very valuable.

The treatment of tubercular orchitis is simple. It consists in the removal of the testicle as soon as the diagnosis is clear; delay is dangerous.

OS CALCIS, Disease of—See Caries and Necrosis.

OSMIDROSIS—See Perspiration and Bromidrosis.

OSTEOMALACIA—See Mollities Ossium.

OSTITIS—See Periostitis.

OTALGIA—See Ear, Diseases of.

OTITIS—See Ear, Diseases of.

OTORRHEA.

As this is but a symptom of some purulent catarrh or deep-seated lesion in the middle ear, the treatment recommended under the heading of Ear Diseases, page 249, is to be followed.

The most scrupulous cleanliness is to be maintained, while the remedies indicated for the treatment of the affection which has led to the otorrhœa are being employed, such as dilatation of the Eustachian tube, removal of diseased ossicles, &c. Syringing with tepid water, to which enough Condy's Fluid has been added as will colour it, is to be carefully carried out twice or three times a day, and after all accumulations of pus and thickened discharge have been flushed out by the stream of liquid, finely powdered Boracic Acid is to be blown in with an insufflator. The hazardous methods of injecting irritating solutions, as injections of Iodine, pure Spirit of Wine, Nitrate of Silver, Chlorinated Soda or Lime, strong Carbolic Acid, Iodoform, Chloral, Sulphate of Zinc, Chloride of Zinc, Corrosive Sublimé, &c., are to be strongly condemned.

When boracic acid fails in diminishing the amount of secretion, a weak solution of the Sulphate of Zinc may be tried. Two grains to the ounce answer all purposes. When the fetor is very marked the amount of the permanganate of potassium, which is added to the tepid or warm water, should be gradually increased as long as its injection fails to produce pain. One grain of Perchloride of Mercury in 1 oz. of pure or absolute alcohol may be used as a solution in which a little cotton wool may be saturated and gently pushed loosely into the canal, where it may be left from time to time, the excess of solution finding its way towards the tympanic cavity. The plug should not be such as will interfere with the free exit of the purulent discharge.

All authorities insist upon the *strictest* antiseptic treatment of purulent otorrhœa, and numerous cases are recorded where a few applications cured the disease when of many years duration. An specula, forceps, &c., are thoroughly sterilized with strong Carbolic Solution or red heat, the canal and fundus of the ear are carefully dried out by borated wool, and the fundus mopped absolutely clean with carbolized (1 to 40) cotton tufts. After gently drying out, a powder is insufflated, consisting of 6 parts of Boracic Acid and 1 part of Iodoform.

M. Shield dwells upon the failure of producing a perfect aseptic condition in perforative otorrhœa by the use of lotions or insufflations, and he incorporates the antiseptic remedy with Oil of Terebroma by making a pellet or minute suppository which can be easily introduced into the meatus.

More recently injections of a 2-4 per cent. Formalin Solution alone or followed by Eka-iodoform insufflations have given excellent results.

OVARY, Inflammation of.

The treatment of oophoritis will embrace often the treatment of the pelvic inflammation (salpingitis and peritonitis) of which it is but a part, or, in other words the treatment of oophoritis means generally the treatment of inflammation of the uterine appendages.

commonly caused by endometritis. In acute cases perfect rest in bed is necessary in the most comfortable position which the patient can discover. This is generally lying upon the back with the legs drawn up.

One smart purge, such as 6 drachms of Rochelle Salt, should be at once administered, and repeated in four hours if necessary.

Leeching is recommended, and the cervix, groin, and perineum may be the seat of application.

Hot fomentations or poultices over which Belladonna Extract has been smeared may be used to give relief, and some recommend ice and cold water coils. Counter-irritation by means of Cantharides, Mustard, Turpentine Stupes, &c., may be tried but for a time such measures sometimes appear to increase the pain. When this is very severe, Opium is necessary; it may be given in very acute cases in the form of a full dose of the hypodermic injection of morphia ($\frac{1}{2}$ to $\frac{1}{4}$ grain), or as a morphia suppository ($\frac{1}{2}$ grain), or as 1 grain of the watery extract of opium, every four or five hours, by the mouth.

The best local application will be the following, sprinkled freely over a circular piece of spongio-piline and applied to the ovarian region (above the groin). It may be worn for hours, a little fresh liquid being sprinkled on from time to time —

- R. *Liniment. Belladonnae*
 Liniment. Chloroformi ana ʒss.
 Liniment. Camphoræ ʒj. *misce.*

As the violence of the pain subsides, the effect of the opiates may be kept up after their suspension by moderate doses of Antipyrine, and 30 grains of Bromide of Potassium at bed-time.

Cannabis Indica is a good narcotic when opium or morphia cannot be used.

At a later stage mild counter-irritation to the iliac region by a daily application of a liniment consisting of equal parts of the tincture and liniment of Iodine may be resorted to with advantage.

The treatment of *chronic* oöphoritis will tax the patience and resources of the physician to their utmost. Owing to the very chronic nature of the affection the treatment cannot be conducted upon the same principles as those which safely guide the physician in acute cases. Thus, absolute rest, to be of any value, must extend over periods so protracted as to seriously injure the patient's general health and vigour. Nor can opiates with safety be employed, as the danger of establishing the opium or morphia habit is very great.

Both these remedies may, however, be employed, under cautious restrictions, during the acute exacerbations which often supervene, especially about the menstrual period, when too

much exertion or exposure to changes of temperature has been indulged in.

Whilst every means is being employed to improve the general health, any possible cause of the ovarian irritation is to be carefully sought out and remedied, often the treatment of the chronic endometritis which causes the ovarian mischief will completely remove it. Constipation must be treated thoroughly, and the patient's own statements are not to be relied upon in this matter. It is not a rare event to find that upon making a vaginal examination the rectum or sigmoid flexure is loaded with faeces, though the patient may affirm that the bowels have been naturally relieved a short time previously, the rectum only partially expelling its contents.

Cascara and enemata of tepid or cold water must be duly employed (see the remedies mentioned under Constipation) until the bowels are brought into a healthy condition.

Chills to the extremities and cold feet, prolonged standing or wearying exercises must be avoided, and sometimes the occupation of the patient should be changed for one affording more regular alternations of open-air exercise and rest. Sexual intercourse should be very much restricted or forbidden.

The only sedatives which can be employed with safety in such a chronic condition are the Bromides. They may be given in full doses in combination with the Iodide of Potassium and a little Belladonna or Hydrastis.

R. *Sodii Bromidi* ℥vj.
 Sodii Iodidi ℥j.
 Tinctura Belladonnae ℥iij.
 Tinctura Hydrastis ℥iij.
 Aquæ Chloroformi ad ℥viij *misce.*

Fiat mistura Sumat ℥ij. *ex aquæ* ℥ij *ter in die post cibos.*

In addition to the sedative action of such a combination it will have some absorbent effect upon any effused products resulting from the long-standing inflammation.

Antipyrine or Antifebrin may be given in moderate doses during the periods when pain is more than usually prominent, or during the intervals in which the above mixture is suspended. Hydrastis alone, and Pulsatilla are useful, and Ergot may be advantageously given when sub-involution is present.

Local treatment may be employed in the majority of instances with marked benefit. It may be directed to causes, such as flexions or versions of the uterus or prolapse of the affected ovary.

A comfortably-fitting Hodge's pessary with the posterior or sacral end composed of India-rubber, often gives great relief as does also a rubber ring, with steel spring enclosed. They place

the posterior cul-de-sac upon the stretch, and support both the relaxed uterus and the displaced ovary.

Copious vaginal injections of hot water may be used twice daily, and if the rectum pipe of the enema apparatus be carefully inserted by the side of the pessary, its presence will be no impediment to their use.

The writer hesitates to express an opinion upon a practice which has the sanction of eminent specialists; but he is inclined to believe that copious hot water vaginal injections, consisting say, of one or two gallons, should not be permitted in patients moving freely about unless a pessary be worn at the same time.

Where a pessary cannot be worn, or is not indicated, the vaginal lamb's wool tamponade, soaked in Glycerin and Ichthyol, should be used. Dudley strongly recommends the Hot Hip-Pack. A sheet folded lengthwise in several plies of about half a yard in width is dipped in very hot water, squeezed out, and applied as a roller bandage round the pelvis and thighs, then covered over with rubber sheeting and a layer of flannel. It can be worn from half to three-quarters of an hour.

Any ulceration of the os or cervix should be treated by appropriate remedies, such as the application of Iodized Phenol or Nitric Acid, though Barnes recommended that a small raw surface, produced by the application of London Paste, should be kept open upon the cervix. The same result may be obtained by lightly brushing over the os with the iodized phenol or Linnent of Iodine.

Counter-irritation over the iliac or inguinal region by means of a small Cantharides blister, kept open by dressing with D'Albepreyre's or other irritating plaster, is often useful. Iodine, Capsicum, or Sinapisms may be substituted. The anodyne liniment, mentioned upon page 641, to be applied upon spongio-piline, may be employed to relieve pain, even when the patient moves about. Baldy recommends Ichthyol, applied over the skin, as a vaginal pessary or by the mouth. Rest, as already mentioned, may be absolutely necessary at the menstrual periods, and when the exacerbations of pain become very severe, at this time hot sitz or very warm hip baths may be safely prescribed.

Electricity is often recommended, but in simple oöphoritis it may lead to increase of the pain, though occasionally a weak continuous current may be employed with great advantage by passing it through the lower part of the abdomen, between large electrodes, placed one over the ovarian region and the other over the sacrum.

By applying the positive pole to the cervix or interior of the uterus and the negative outside the abdomen, pain is often markedly relieved. The use of the current, as in Apostoli's method, finds no favour with many specialists.

Pelvic Massage with the right, the uterus being elevated by two fingers of the left hand introduced into the vagina, as in Brandt's method, has been highly recommended, but there is room for

very sharp differences of opinion regarding the wisdom of such practice; it thus should exist in the tubes the result might be disastrous. It must be confined to the hands of specialists.

Where, notwithstanding all treatment, the affection continues to harass the patient, the question of removing the diseased ovary and tubes must be seriously considered. This may be done best, as a rule, by opening the abdomen in the median line and removing the ovary or the Fallopian tube, or both of these appendages in the operation of ovariectomy. The removal of prolapsed and adherent ovaries by the vagina is less satisfactory; often abdominal and vaginal section may be necessary in the same case.

OVARIAN TUMOURS.

The various methods of treatment which were in former times (before the brilliant achievements of modern surgery were dreamed of) employed, with the forlorn hope of curing or preventing the progress of the growth, have fallen into disuse.

Thus, drugs for internal administration, as iodides, mercurials, diuretics, &c., are known to be worthless, and are now never depended upon. Injections of iodine and other substances into the tumour are now little practised, though by injecting simple monocystic ovarian tumours in former years sometimes excellent results were obtained. Sir James Simpson, for instance, had only one failure in twenty cases, though other surgeons have reported most unfavourably of the operation. It often fails entirely and sometimes causes death, and the practice is now replaced by excision.

In a large ovarian cyst of many years' duration which came under the writer's notice when its contents had become purulent, and were oozing through a minute orifice at the umbilicus, it was apparent that it had formed adhesions in every direction and to the abdominal wall, excision appeared to him to be out of the question, and he recommended one large incision into the suppurating cavity of the cyst where it was adherent to the parietes, and the establishment of thorough drainage and washing out with antiseptics. This was done with complete success.

Tapping or aspiration of the contents of an ovarian cyst is a practice which the most experienced specialists in this department are steadily condemning. In some cases of cysts in the broad ligament, their tapping has effected a cure, and Keith adopted this method of treating all such cases; but for the treatment of cysts of the ovary, success is much rarer than the supervision of serious drawbacks, such as hæmorrhage, peritonitis, suppuration, &c., which occasionally have caused death, or which often have led to the formation of extensive adhesions, the presence of which has seriously affected the removal of the tumour at a later stage.

There can hardly be a doubt about the wisdom of totally discarding the tapping of ovarian cysts as a means of cure, independent of excision or ovariectomy. In a limited number of

cases the writer has seen one death directly follow tapping of a large cyst by a skilful surgeon. Occasionally, for purposes of diagnosis, tapping may be necessary, and it is well, if in such a case, the operation of ovariectomy could be immediately proceeded with.

Tapping is admissible as a method of giving relief in cases where an operation is unjustifiable, as in a patient suffering from cancer or other incurable affection, or as a method of tiding the patient over pulmonary, renal, or other embarrassments, caused by the pressure of the tumour, till her general condition becomes so improved as to warrant operation.

The tapping should be conducted under the strictest aseptic precautions. A long, fine trochar and canula, after being well washed in a weak sublimate or strong carbolic solution, may be plunged into the cyst in the middle line, midway between the umbilicus and pubes, as the patient lies upon her side close to the edge of the bed.

To the canula is attached a long piece of rubber tubing, the free end of which is dropped into a pail containing a little carbolic lotion. This precaution prevents the possibility of air being allowed to enter the cyst. The instruments devised by Wells, Thompson, Tait, and Ward Cousins answer well. The writer has generally used the largest sized trochar and canula belonging to Druke's aspirator. Aspiration is seldom necessary, and large trochars, such as formerly were used, are not advisable.

After the contents of the cyst have been drained or syphoned off by the above method, a small pad of lint may be placed over the opening, and kept in position by a few strips of plaster, and a broad bandage or binder should be applied as tight as comfort will permit, and the patient should be directed to lie upon her back for the first twenty-four hours, as this may diminish the chances of the cystic fluid dribbling into the peritoneal cavity.

The operation of ovariectomy is, by the common opinion of surgeons, recommended to be undertaken before the tumour has assumed large proportions. It is admissible, however, in the most advanced stages of ovarian degeneration, and has become the safest and most satisfactory major operation in surgery, as remarked by Greig Smith, who quotes the remarkable results of Tait, in which no death resulted after 139 ovariectomies. The reader is referred to any of the special works for the details of ovariectomy, as only a brief sketch of the operation is here admissible.

The most suitable time for operating is about 4 to 8 days before the next catamenial discharge is expected.

The patient should have the bowels well cleared out by a mild cathartic or warm water enema, and the catheter should be passed before the operation is commenced. No food is to be permitted for 3 or 4 hours before the administration of the anæsthetic, and then an egg beaten up with milk or a large cupful of strong beef

tea should be all that she is allowed. An ordinary night-dress over which a warm flannel jacket is worn, and woollen stockings on the legs, afford the most convenient and comfortable dress. The patient is placed upon the operating-table in a well-ventilated room, kept at a temperature of about 75° F. The day before operation the front of the abdomen should be thoroughly cleansed by soap and water, followed by turpentine and ether to remove greasy matters, after which a pad soaked in Sublimate or Carbolic Solution should be kept on all night, and after Chloroform, Ether or ACE Mixture has been administered, and the surgeon has seen that every precaution has been taken to avoid unnecessary cooling of the surface of the body during the operation by the sudden disposal of warmed blankets or cotton wool, the abdomen is exposed and a large mackintosh sheet, sufficient to cover the trunk and to project beyond the feet of the patient, is laid over her. This sheet has an oval aperture whose margins are smeared over with adhesive plaster, by means of which it is fastened to the abdominal parietes, leaving the site of the incision uncovered and corresponding to the oval, whilst it covers over and protects from moisture the entire trunk and legs of the patient, and projects beyond the limits of the operating-table as she lies upon her back with the head and shoulders slightly raised, or in the Trendelenburg position. Many operators discard the mackintosh-sheet with its old fashioned aperture and plaster.

All instruments are to be boiled in a weak alkaline solution. A specified number of gauze pads (generally 12) should be sterilised and ready for use. As they are soiled during operation, they should be rinsed in boiled water or sterile saline solution. They should be carefully counted over before and after operation prior to the closing up of the abdomen, so as to prevent the possibility of any being left behind.

Each operator has his own list of instruments. The following will meet most cases of ovariectomy—A scalpel or straight bistoury, at least one dozen of Wells or Tait's hæmorrhagic forceps, one or two pairs of ordinary artery forceps, two pairs each of large and medium cyst forceps, Wells or Nélaton's, one vulsellum, one Tait's large and one Wells' small or medium cyst trochar, with rubber tubing; scissors; one Adams's hook, two mounted pedicle needles, one needle-holder and needles; suture one clamp, cautery irons, drainage tubes.

The incision is made in the middle line, its length depending upon the size of the emptied cyst, its lower limit should be two inches above the pubes, and its upper may be necessarily prolonged close to the left side of the umbilicus. Sometimes an incision two inches in length may suffice, and the writer has seen to inches necessary in one case.

The first few strokes of the knife should divide for about two inches all the structures down through the fibrous aponeurosis till the transversalis fascia is reached. Bleeding points are to be

secured by artery forceps, and the peritoneum is then to be opened by knife and director, or scissors, as in hernia operations.

With the exposure of the cyst the operator should at once proceed to tap it without venturing to explore or break down adhesions, and after the fluid has ceased to run, any secondary cysts are to be also emptied through the original opening or broken down by the insertion of the hand or fingers. When this has been accomplished the operator applies a clamp to the opening in the cyst, and makes gentle traction upon the collapsed tumour, while he explores for adhesions which are to be broken down with the fingers or by the pressure of a gauze pad if soft and recent. In the separation of adhesions the greatest patience and judgment are necessary to determine the amount of force justifiable. Adhesions, which are so firm as to resist traction short of producing rupture of organs, must be treated by excising the adherent portion of the cyst-wall and leaving it *in situ*. After the removal of all adhesions the collapsed and flaccid cyst is gently extracted through the abdominal opening, which may have to be enlarged for this purpose. As the tumour is withdrawn from the abdomen, the pedicle is brought into view; the treatment of this is open to grave variations. Some surgeons tie it in one mass, others tie it in sections; the stump has been left outside, returned into the cavity, clamped, cauterised, twisted, tied with catgut, wire, and silk. The clamp and cautery method is still used by some operators, but the rule may be generally said at present to be transfixion of the pedicle by an armed mounted needle, and the tying of each half with a stout silk ligature, cutting the pedicle moderately close with a knife and dropping the ligatured end back into the abdomen. A large gauze pad is placed over the intestines as soon as the tumour has been extracted, and before the pedicle has been secured.

After the pedicle has been satisfactorily disposed of, the operator proceeds to clean out the abdominal cavity, removing by the gentle and diligent use of gauze pads squeezed out of warm saline solution every vestige of blood or foreign matter from the peritoneum. Lint or sterilised gauze pads held in long ovum or polypus forceps should be pressed down into the hollows about Douglas's space, and frequently withdrawn and re-applied till there is nothing to take away. Tait washed out the abdominal cavity when there had been much foreign matter exuded. This he accomplished by pouring in large quantities of warm water and moving the intestinal coils about with the hand till the water flowed out clear. Many operators flush with Boric, and others with weak Salt Solutions. Any bleeding point caused by the separation of the adhesions is to be secured by catgut or silk ligatures, twisted or touched by the thermo-cautery.

When the toilet of the peritoneum has been satisfactorily carried out, several dry gauze pads may be placed in the most dependent parts of the abdominal cavity, and left there till just before the

closing up of the wound by the approximation of the sutured edges. A glass drainage tube (Keith's) or gauze drain should be inserted where there is any reason to expect weeping, especially in cases where there has been troublesome adhesion of the cut wall to the deep parts of the pelvis. The end of the tube should dip down deeply into Douglas's pouch. It will seldom be required in cases operated upon antiseptically. Sutures are to be carried through all the structures entering into the abdominal parietes the lowest one being inserted first. The peritoneum is also to be embraced in the sutures, close to the margins of the wound. Before adjusting them, all pads are to be removed and counted and the drainage tube (when necessary) inserted. The edges of the wound are to be accurately brought together, without placing too much tension upon the sutures. A pad of several layers of carbolic gauze is laid over the line of incision, and held in its place by a series of broad strips of adhesive plaster, which should extend from each loin to the opposite, so as to firmly support the entire abdomen. When this is properly done, there is little necessity for an abdominal binder, though no harm can result from placing a neatly-fitting broad flannel bandage or binder over the whole and where the distension has been very great, a large pad of cotton wool or a large folded napkin may be secured in its place over the strapping by the flannel, so as to give additional support and to minimise the sensation of emptiness which the patient often feels.

The after-treatment of ovariectomy is of vital importance, and as it often falls into the hands of the ordinary medical attendant after the departure of the specialist who has operated, he should study it more carefully than the steps of the operation.

The best position for the patient after operation is upon her back in bed, upon a good hair mattress, with the shoulders and head elevated, and the legs supported or raised by a pillow placed under the knees. It is, however, a mistake to insist upon this or any other position being steadily maintained. On the other hand it is decidedly advantageous in this as in other abdominal operations to have the patient moved occasionally on to one or other side as tending to prevent intestinal distension. One matter must be impressed upon both patient and nurse—i.e., that when a change of posture is desired it should be accomplished slowly and deliberately by the assistance of the nurse. Where a drainage tube has been inserted the nurse should be instructed by arranging and rearranging the sheets and pillows, to soothe the patient, and if possible prevent her turning over on her side. Hot water bottles or extra clothing for the first few hours may be necessary.

Regarding diet, Smith recommends for the first 24 hours nothing but small quantities of hot water or hot toast-water, in the next 24 hours a little oatmeal gruel or essence of meat given with the water. Afterwards, he states, "If the case is doing well, the

patient may have almost what she asks for." This latter advice is to be accepted with caution, and unless the case is in the hands of a most discreet and experienced nurse, it should be the duty of the physician to look closely after the diet. If vomiting supervenes, a little ice may be permitted. In severe cases a copious drink—say a pint of hot water—may be given, which will likely be rejected, and thoroughly empty the stomach. Washing out the stomach has proved effectual for persistent vomiting. Generally, however this symptom, when it persists, is due to pseudo ileus or to peritonitis, and attention must be directed to the cause.

The writer has seen much mischief produced by ice administered too often and in too great quantities. When thirst is great, Smith's plan of giving an enema of one pint of tepid water is often more efficacious. The fear of inducing vomiting should lead the nurse to give as little of anything as possible by the mouth. Water may accumulate in the stomach after ice has been given too freely, and vomiting may be thus produced. When the operation has been a severe and protracted one, as soon as the patient is permitted two or three hours rest, three or four ounces of warm strong beef tea should be injected into the rectum by a rubber bottle and pipe of a capacity not greater than the amount of the injection. Some operators begin and continue rectal feeding in every case as a matter of routine for the first three or four days. This is often unnecessary, and the risk of producing rectal irritation or uneasiness should not be lightly undertaken.

Milk is condemned as a food by many, but this is probably because it has been injudiciously administered. Greig Smith strongly condemned it unless peptonised. After the first eight hours or so a table-spoonful of milk, mixed with an equal quantity of effervescing Potash Water, is a convenient, safe, and agreeable method of introducing nourishment into the stomach, but during the first 24 hours the total quantity administered should not exceed at the most 10 ozs. of milk. Buttermilk suits many patients admirably.

During the second day this amount may be doubled if all goes well, and no nausea or vomiting be excited.

The milk may be, however, soon suspended for beef tea, cold chicken jelly, or warm chicken soup, if relished. The danger to be avoided is in forcing nourishment too frequently upon the patient. Arrowroot fine sago, or farola may be given in small quantities after the first 24 or 36 hours. Weak tea and thin bread and butter, or dry toast, may be permitted upon the third or fourth day, and fish, chicken, or a little lean chop upon the fourth or fifth, and after about the seventh day an ordinary diet may be cautiously commenced. The complications and symptoms which occasionally arise will, of course, modify the above dietary, signs or symptoms of peritonitis forbidding the administration of animal food.

The routine practice of administering opium or morphia immediately after every ovariectomy is objectionable. These should

only be given when severe pain or extreme restlessness supervenes. The best form is the morphia perule and $\frac{1}{2}$ grain will generally be sufficient. It can scarcely be vomited owing to its minute size and spherical form, and perules containing $\frac{1}{4}$ grain may be given every two, three, or four hours when necessary.

The forms of suppository and hypodermic injection are preferred by many but the perules appear to check nausea and vomiting. In those cases where rectal feeding is necessary the opiate may be judiciously administered in the form of Laudanum mixed with the enema.

Thornton recommends frequent washings out of the stomach by means of a soft rubber tube, where peritonitis exists in conjunction with bilious or dark vomiting.

Where tympanitis or severe abdominal distention supervenes early, the rubber tube may be passed up the rectum, but this seldom does any good, and it is a mistake in such a case to wait till the sixth or seventh day before having the bowels relieved. A smart Saline purge given upon the third or fourth day generally affords speedy relief and often appears to ward off the threatened peritonitis. Many authorities insist upon the great value of early saline purges when the pulse rises to above 100 and refuses to fall.

Four drachms of Rochelle Salt dissolved in 5 ozs. of aerated lemonade may be given, and repeated, if necessary, in five or six hours, though some physicians prefer a dessert-spoonful of Castor Oil, and others recommend 1 gr. Calomel every hour.

The catheter need not be passed for 12 or 18 hours after the operation, unless the patient expresses uneasiness, as there is generally but a small amount of urine secreted at first. The catheter should be kept scrupulously sterile, and each time before and after use it may be dipped into the Glycerin of Borax which effectually prevents the introduction of any living organism into the bladder or urethra. Its application should not be delayed beyond every 12 hours at the most after the first day. If the patient be unable to pass water without assistance, every 8 hours will generally be found to answer.

The wound will require little attention. It need not be touched till the expiration of seven days, unless a drainage tube has been inserted. Where this has been found to convey but a little oozing it may be removed after the first day, and the aperture closed by a suture inserted loosely at the time of operation. At the end of the first week in ordinary cases the pad of gauze is to be removed with the strapping by bathing or moistening the parts with warm carbolic lotion. The sutures are also to be snipped and removed, a fresh pad of gauze adjusted, and bands of adhesive plaster applied as before to give support to the abdominal parietes. The binder may be re-applied, and the wound again left undisturbed for another week, at the end of which it will generally be found to be thoroughly united.

About 14 days is generally found to be a sufficiently long period for keeping the patient in bed. After this time she may be permitted to sit up, and in three weeks may leave her apartment, and, if a suitable bandage is applied, she may be permitted to drive about. She should be cautioned to take rest and special care during the first and second menstrual periods succeeding the operation.

When the temperature is found to rise after the operation, it may be wise to give some simple diaphoretic mixture and await events. The surgeon should not attach too much importance to the elevation of temperature, as trivial causes may send the thermometer up several degrees, whilst dangerous peritonitis may be present with a fractional increase of body heat.

Where the fever continues high some means must be employed to reduce it. The ice-cap or Leiter's tubes to the forehead or scalp is often resorted to. It is doubtful if these produce any marked effect in cases which warrant any antipyretic remedies.

Persistent high temperature must be met by prompt action, and hyperpyrexia though rare, will probably soon prove fatal unless speedy reduction of temperature is effected by active remedies.

In one case—a patient of the writer's—the temperature reached 108° inside 24 hours after the operation. In such a case probably no treatment is of any use, but the only means worth trying is the cold wet pack, which may be applied to the entire body, and the sheets frequently changed or saturated with iced water till the temperature falls to the normal. Mild cases yield to iced cloths placed over the legs and thighs and arms, but in high temperatures the trunk must be also included in the pack.

Where the rise of temperature is persistently high, and accompanied with great distension of the abdomen, the surgeon should strive to treat the cause. Where this is owing to the accumulation and retention of decomposing secretions within the abdomen, steps should at once be taken to give exit to the offending matter when the condition of the patient looks grave.

This may be accomplished by the removal of the sutures from the lower half of the wound, and the thorough washing out of the abdominal cavity by a copious stream of warmed antiseptic liquid, as weak carbolic lotion or boracic solution. The surgeon should introduce his fingers or hand into the cavity, and separate any agglutinated coils of bowel, and in bad cases of peritonitis the abdomen has been successfully re-sponged out and the wound sutured up again. In all such cases there must be free drainage established, and the glass tube should be inserted deep into Douglass pouch with the collar resting between the edges of the abdominal wound. A loose roll of carbolised or iodoform gauze is placed inside the tube, and a carbolised sponge over its open extremity. When the tube remains *in situ*, the gauze in its interior draws up any moisture. This percolates also into the sponge. These should be renewed every eight or ten hours under the

carbolic spray, and sometimes, when the discharge gets scanty, Tail's suction apparatus may be employed.

Some surgeons in these cases puncture the pouch of Douglas through the vaginal walls by means of a long trochar and canula which is left in the wound, or a drainage tube is inserted as the canula is withdrawn.

The temperature, when depending upon causes such as have been referred to, generally falls upon the drainage being provided. If not, it is certainly worth while to give an antipyretic. Quinine is not generally reliable. The amount necessary to make a decided impression upon the temperature often upsets the stomach and digestion. Antipyrine is safe and convenient, and may be given in doses of 15 grains every 4 or 6 hours till the temperature falls to normal. In peritonitis this must be given by the rectum, as vomiting is so constantly present. For the same reason all feeding by the mouth must be given up, and the patient should be fed entirely by enemata of beef tea or peptonised foods. Ling Smith's routine enema consists of—1 ounce of Brandy, 1 drachm of Valentine's Beef Juice, or 1 drachm of Brand's Essence or 1 drachm of Benger's Peptonised Jelly, and 4 ounces of Peptonised Milk.

This is to be given every four or five hours, and once in the 24 hours an enema of tepid water, to the amount of one pint, is to be administered, and the rubber rectum tube worn for about an hour before each enema.

These precautions are necessary, as it is most undesirable and sometimes dangerous to allow the decomposing or putrid remains of the enemata to lie and accumulate in the rectum, especially as the mucous membrane may have suffered some abrasions from the frequent introduction of the anal tube.

With the rectal feeding and small quantities of ice by the mouth and an antipyretic when needed there only remains, for the peritonitis Morphia given in proportion to the pain present. The best way to administer this is to give one full dose by the hypodermic method, after which the effect may be kept up by giving a perule containing $\frac{1}{2}$ grain every hour by the mouth till the pupils are markedly contracted and pain relieved.

Turpentine enemata rarely do any good, and they may seriously interfere with rectal feeding by setting up irritation.

OXALIC ACID POISONING—See under Poisoning.

OXALURIA.

The pathology of this condition still requires elucidation, and there is no special or specific treatment for it. In every case the first thing to do is to determine the cause of the unpaired metamorphosis, and have this removed or corrected. When this is caused by some error in digestion or assimilation, suitable tonics are indicated, and by far the most valuable are the

Mineral Acids, 20 minim doses of the Diluted Nitro-hydrochloric Acid in Infusion of Calumba being very useful. When over-eating is the cause, especially when much animal food and acid wines are indulged in, the best treatment will be a wise regulation of diet, and strict temperance in all things. Often cooked rhubarb brings on very severe oxaluria, and saccharine foods sometimes produce the same effect.

The writer has seen the condition disappear upon changing the eating habits of the patient. Thus the heavy dinner indulged in after partially fasting all day may be the cause of oxaluria, and by getting the patient to dine in the middle of the day, and to take a light meal in the evening, the amount of oxalic acid or oxalate of lime becomes rapidly diminished. Large eaters should take a bottle of simple carbonated or aerated water instead of tea, concentrated soups are not to be recommended. Yeo recommends a large draught of hot water in the early morning with Carlsbad Salt dissolved in it.

Want of free exercise in the open air often leads to retarded metabolism, and a change of life in this respect may lead to the speedy disappearance of oxaluria when the ill-ventilated office or workroom is abandoned for the fresh breezes of mountain or sea-side resorts. Sleeping-room ventilation should be looked after, and the bedroom window left open all night is an advantage. For the anxious, over-worked city clerk who drives to his small office in the morning, and drives home again in the evening to spend the hours till bed-time in the close atmosphere of a gas-heated room, cycling is a good practice.

Sleep should be sound and natural, and all conditions interfering with this must be attended to, neuralgia, insomnia, over-work, or high pressure being remedied as far as this is possible. Often serious happiness, neurasthenia, and melancholia are found associated with the disorder, and until the psychological condition be remedied the acid continues to be excreted in large quantity.

Sea bathing, the Turkish bath, or, better still, a good shampooing or massage after perspiration has been induced by brisk or even violent exercise, is of use. The morning shower bath is to be recommended, and the clothing should be warm and waterproof.

Roberts recommends the administration of Bicarbonate of Potassium when the signs point to gastric irritation, and the Mineral Acids when atonic dyspepsia is present.

To sum up, the treatment of oxaluria will consist in the vigilant and persevering look-out for the violation of some health law, which, being discovered, should be at once remedied.

OZÆNA.

The treatment of this unpleasant affection, commonly caused by chronic atrophic rhinitis, may be summed up in the words—absolute cleanliness. Where this is rigidly and perseveringly carried out, the worst cases may be expected to yield.

The great difficulty in dealing with ozæna is to remove the thickened secretion upon whose presence the fetor depends. Every crust should be washed away, and no mucus be allowed to accumulate. As long as secretions are permitted to remain, decomposition speedily sets in, and the diseased surface is never placed in a condition favourable for healing. Hence the necessity for the persistent use of the nasal douche, which consists of a soft rubber tube, with a nose piece at one end and a lead sinker at the other. This latter is dropped into a jug of warm water, in which a tea-spoonful of common Salt or Bicarbonate of Soda and Borax is dissolved, and after starting the fluid to run syphon-wise through the tube, the jug is elevated as the end of the douche is inserted into one nostril. By keeping the mouth wide open the soft palate is raised and the posterior nares cut off from the mouth and pharynx, and as the water flows in through one nostril it courses round the nasal chambers and flows from the other nostril.

This should be continued till every trace of thickened secretion is removed, and at first, or in neglected cases, hot fomentations and inhalation of steam may be employed to assist in the removal, and where the dried discharge adheres to the roof of the nasal cavity, an ordinary enema syringe may be employed to wash it out, or it may be mopped out by pledgets of cotton wool twisted round a probe.

After a few applications of the douche, its constant employment becomes a comparatively easy matter, and if used three or four times a day, the mucus or pus has not time to desiccate, and a few minutes are sufficient to cleanse the cavity. During the douching the nose piece should be taken out of one nostril and inserted into the other.

When the crusts are removed, an antiseptic solution should be substituted for the Salt or Bicarbonate of Soda liquid. Every known substance possessing deodorising properties has been recommended or used, of which a few are subjoined. The quantities mentioned are to be dissolved in 10 oz. water.

Potassium Permanganate, 2 grains, or 2 drachms of Condy's Fluid to 10 oz. water; Chloride of Zinc, 2 grains; Sulphate of Zinc, 30 grains; Jeyes' Disinfecting Liquid, 60 minims; Carbolic Acid, one drachm; Santal Fluid, one table-spoonful; Chlorinated Soda Solution, one tea-spoonful; Nitrate of Silver, 4 grains; Sulphurous Acid, 2 drachms; Alum in Powder, 40 grains; Glycerate of Borax, a table-spoonful; Chlorate of Potassium, 30 grains; Glycerin of Tannin, a dessert-spoonful; Tincture of Iodine, 30 minims; Boroglyceride, 2 drachms; Boracic Acid, 2 drachms; Naphthol (see below), 5 to 10 grains; Hydrate of Chloral, 5 grains; Perchloride of Mercury, 1 to 2 grains.

Any of the above solutions may be used, and the surgeon will be wise who confines himself to the use of any one or two of them instead of changing from day to day. The astringents in the list

may be selected where the discharge is copious, and the deodorizers are indicated in proportion to the amount of fetor present.

Beta-naphthol has been most successfully employed by Ruatt. He washes out the nose with a fresh solution of 60 grains of Borax and the same amount of Bicarbonate of Soda, in one pint of water, to which a tea-spoonful of the following solution is then added—*i.e.*, Naphthol (Beta-naphthol), 1 drachm, dissolved in 1 oz Alcohol (90 per cent.). In obstinate cases he inserts for 15 minutes after using the above, cotton tampons saturated with the following:—

Naphthol (Beta-naphthol), 12 grains; Tincture of Quillaia, 14 drachms; Distilled Water, q.s. to 1 fluid ounce.

Siddo washes out with a 2 per cent. solution of Pot. Chlor., to which 10 per cent of Glycerin is added. After removal of all thickened secretion, he inserts for one hour daily, cotton tampons saturated in Glycerin, 1 part, and water, 3 parts.

Rossenbach paints the interior of the nose with Peruvian Balsam and leaves tampons saturated with it in contact with the deeper parts of the cavity. This treatment effectually destroys all fetor, and the same result is claimed for a 1 per cent. solution of Trichloroacetic Acid, and 1 in 500 solution of Formalin.

Boracic Acid, Bismuth, Camphor, Tannin, Calomel, and Iodoform, suitably diluted with chalk, sugar, or starch, have been used for insufflation, but they are less satisfactory than liquid preparations. Hamms insufflates a powder consisting of equal parts Citric Acid and Sugar of Milk thrice daily, and states that all odour promptly ceases. Where there is much discharge Tannoform answers well.

After the use of any of the above irrigating liquids, the speculum may be employed, and any ulcerated spots may be touched with strong solutions of the same antiseptic agents, with Iodized Phenol, Ethyl Iodide, Perchloride of Iron, Ethylate of Sodium, the Galvano- or Thermo-cantery, Nitrate of Silver, or Nitric Acid.

As a rule, ulcers rapidly heal under constant irrigation and spraying by weak saline or antiseptic solutions.

When diseased bone is present (as is seen in cases which are not atrophic rhinitis) little improvement may be expected till this has been removed, which, as a rule, can be easily accomplished by seizing any loose bone in a pair of small sequestrum or stout dressing forceps, and gently dragging it through the nostril. When the dead bone is too large for removal in this way, or when it cannot be easily reached, Rouze's operation of turning up the lip, and dividing the mucous membrane and all the structures above the anterior teeth by a horizontal incision, may be tried. After detaching the cartilaginous septum from the anterior nasal spine, the finger may be passed into the nasal cavity, and by the aid of suitable forceps any diseased structures may be removed.

Hunter Mackenzie's treatment consists in curettement for sep-

insufflated in such cases with advantage.

Constitutional treatment is of great importance, as urgently required in the stramonium, and in the remedies suitable for these varieties of disease, and Syphilis.

In every case the general health must be improved by food, pure air, change of scene, tonics, such as Arsenic, Quinine, sea bathing, &c., in addition to local treatment.

PAGET'S NIPPLE—See Nipple, Diseases of.

PALATE—See Cleft Palate.

PALPITATION—See Heart, Diseases of.

PANCREAS—Diseases of.

Of the pathology and symptomatology of the pancreas is known, and of their treatment still very little. The treatment will resolve itself into medical and surgical. Though surgical treatment has been attempted, it seldom can be considered justifiable in the majority of cases. Acute and hæmorrhagic pancreatitis is beyond the reach of art, except in so far as it may be relieved. Where there is reason to suspect chronic pancreatitis, administration of the extract of the pancreas, coated with keratine will supply the deficiency, and the writer has satisfied himself that this treatment results in diabetes of pancreatic origin.

Mayo Robson has operated upon 41 cases of pancreatitis, and many of these were supposed to be chronic interstitial pancreatitis. He resected the pancreatic duct through the accor-

In one case where a large tumour, closely simulating an aneurism, formed after a severe localised injury to the abdomen, the writer tapped the tumour, the contents of which were found by Professor Matthew Hay to consist of pure pancreatic juice. Gallons of this fluid were removed from time to time but the patient did not suffer from any of the symptoms supposed to always follow the arrest of the secretion of the gland, though the enormous quantities of fluid, possessing in a very active form all the physiological qualities of undiluted pancreatic juice, continued to be removed by the aspirator for many weeks. The tumour, after one of theappings, rapidly filled up with a bloody liquid. Symptoms of peritonitis supervened, and the patient made a rapid and complete recovery, and remains perfectly well, now 15 years since theappings, and the pancreas shows no signs of the presence of any cystic growth, the patient being well nourished and vigorous. In chronic pancreatic diseases the use of pancreatised food or of Benger's preparation is indicated.

Calculi, when detected, may be submitted to manipulation or taxis which has been successful in a few cases. If this fails, abdominal section may be performed.

PANNUS—See *Conjunctivitis* (Page 162.)

PARALYSIS—See under *Hemiplegia*, *Meningitis Spinal*, *Myelitis*, *Caries of Spine*, &c.

PARALYSIS AGITANS.

The treatment of this affection is most unsatisfactory: eminent authorities have reported great improvements in several cases following the use of remedial agents, which, upon further clinical experience, have proved valueless. The most hopeful therapist will hardly be likely to continue to push drugs which do not give evidence of doing some good inside a reasonable time, and yet the best treatment may be found ultimately to consist in the exhibition of some agent whose action is very slow. The writer has prolonged the trial of various substances generally to find that in the end the case pursued its own course. The reports of cases which speedily commenced to improve after the use of certain agents are not to be wholly discredited. The explanation possibly lies in there being a moral or psychological effect following their administration. Reports of cases where a permanent improvement or cure followed the use of any line of treatment are exceedingly rare, though it is related that Brown-Sequard cured one case with Chloride of Barium, Elliotson another with Subcarbonate of Iron, and Reynolds a third with Galvanism applied to the spine.

The best effects are probably secured by the prolonged use of Arsenic internally and a continuous current applied to the affected muscles or limbs. Fowler's Solution may be given in doses, commencing with 3 minims, increased gradually to 10 minims three

times a day after food, and a current from 8 to 16 Léclanché may be sent through the affected region daily for 10 to 20 minutes. Sometimes good effects have been observed by injecting Fowler's Solution (2 to 3 minims) subcutaneously, or deep into the muscles. Gowers has obtained best results from Arsenic combined with a little Strychnine, and Indian Hemp, and gentle rubbing of the affected region with the hand, he lays stress upon the importance of quietness and regularity in the patient's habits.

Chloride of Barium appears to possess power over some cases. It may be given in doses of $\frac{1}{4}$ grain, three times a day.

Valerian, in large doses, to grains of the extract, or dessert-spoonful doses of the simple tincture may be tried. The writer has seen some good effect from the Valerianate of Zinc, but only when given in such doses as cannot long be taken without upsetting the digestion and appetite, and causing headache—i.e., 5 to 8 grains three times a day. Small doses are useless.

Erh has given Hyoscine with remarkable benefit. It acts speedily, and has been found to stop the movements with tolerable certainty, and often they have been found not to return for a considerable period after the action of the drug had ceased. It is given hypodermically in doses of $\frac{1}{32}$ grain of Merck's preparation. Williamson reports marked benefit from $\frac{1}{4}$ grain by the mouth.

There is, however, no evidence of its permanent effects, and in an affection of such long duration there are grave objections to the use of powerful remedies which only give temporary relief. In severe cases of the disease where the movements seriously interfere with the patient's rest, it is of the greatest possible advantage to possess such a remedy, and by its use life may be comfortably prolonged; but such cases are rare. Taylor has obtained marked benefit from passive movements, massage in a graduated system of voluntary movements and exercise. Moderate support to the affected limb may be also of use in severe examples of the disease, though anything like restraint as bandaging to splints, &c., aggravates the mischief. Bandaging may be useful in the early stages of the disease. Suspension has been tried, and the injection of Testicular Fluid and Brain Emulsion, but the results are unsatisfactory. In mild cases a mixture of the following may be given for long periods with marked relief:

- R. *Hyoscine Hydrobrom.* gr. $\frac{1}{4}$
Tinct. Hyoscyami ℥iss.
Phenazone ℥iss.
Tinct. Valeriana ℥iii.
Glycerini Purificati ℥iss. misc.

Capiat drachmam ter in die post cibos ex paululo aqua

In one typical case under the writer's care of paralysis agitans without the agitans, the above hyoscine mixture always gave relief, but it often caused retention of urine.

Strychnine, Phosphorus, Atropine, Iodide of Potassium in large doses, Opium, Calabar Bean, Chloral, Bromides, Ergot, Curare, and many other drugs have been employed, but with very little benefit to tempt one to hope for permanent improvement.

Cod Liver Oil and Iron with hydropathy may often prove useful in raising the tone of the general health.

Gowers in a recent article states that of all the degenerative diseases of the nervous system this is the least amenable to therapeutic agents, and the least capable of diversion from its progressive course. It is the shadow of that which has to come.

PARALYSIS, Alcoholio.—See also under Neuritis.

If the patient be seen in the early stage of the disease there will be every reason to believe that an absolute cessation of indulgence in alcohol in every form will enable him to recover. There are, however, several points in the pathology of alcoholic paralysis still to be worked out. For example, the disease is comparatively rare in districts like Belfast and Glasgow, where alcohol, in the form of a comparatively pure spirit, is largely imbibed. These and other considerations suggest that there are probably other factors in the disease, as hinted at by Reynolds in his evidence before the Royal Commission investigating the cause of the poisoned beer epidemic. It is more than probable that many of the typical cases of alcoholic neuritis of the past were cases of combined alcohol and arsenical poisoning. Suckling has pointed out that recovery may be even expected where the disease has lasted over a year. If, however, the muscles fail to respond to the interrupted current, and the reaction of degeneration be present he points out that treatment must be very perseveringly tried before benefit begins to appear. Treatment in all cases will consist in total abstinence from every form of alcohol, rest in bed, the judicious use of the continuous and interrupted currents, with daily massage and counter-irritation by means of a series of flying blisters over the course of the nerve trunks.

Internally and hypodermically Strychnine is the only remedy to be relied upon. The general management of the case may be carried out upon the lines mentioned under Paralysis, Diphtheritic, and as the condition is associated with or follows alcoholic neuritis, see under the heading of Neuritis, on page 610.

PARALYSIS, Diphtheritic.

The treatment of diphtheritic paralysis is simple; it resolves itself chiefly into a question of feeding. There are few affections in which the physician may more safely indulge the hope that by his interference he can often prevent a fatal syncope and save life. The disease is certain to disappear completely if the patient's life

can only be sustained long enough for the elimination of the poison causing the paralysis. This is, however, sometimes a very slow process, and when the cardiac or respiratory muscles are affected there is great danger of a sudden wind up to the case, and the physician must be on the look out for the first symptoms of cardiac weakness, which are to be met by free stimulation and Ammonia with Strychnine. In the very onset of the paralysis occurring sometimes within a few days after recovery from diphtheria, or during the course of the disease, the heart muscle may be the first to suffer from weakness, and when the first symptoms of this are overlooked by the physician, sudden death may be the first change which shows the effect of the diphtheritic poison. As soon as the pulse, and temperature of the chest and extremities show any evidence of cardiac weakness, the patient must be treated with promptness. He should be put to bed and warmth with friction applied to the limbs, whilst a small sinapism is applied over the heart, and whiskey or brandy given in warm milk, both by the mouth and by the rectum. Ammonia, in the form of strong liquor, may be applied to the nostrils, and *Sa. Volatile* in full doses, well diluted, may be administered every 15 or 30 minutes, whilst Faradisation of the precordial region may be resorted to in severe cases.

Where paralysis of respiration threatens, artificial respiration and Duchenne's plan of reflex stimulation of the respiratory centre by Faradism of the back and chest may be resorted to.

In the more common form of the affection where the weakness begins in the lower extremities or in some of the peripheral muscles, as in the eye or palate, the paralysis comes on at a later period often within a fortnight or month after recovery from diphtheria, though the danger of sudden cardiac failure is much less, these cases are apt to be very tedious, and before recovery almost every muscle in the body may become paralysed. Feeding should be rigorously attended to, and as soon as swallowing becomes difficult or impossible rectal alimentation must be commenced. In every way that is possible the nutrition of the body is to be improved, and when the appetite is weak, *tonics*, such as the well-known combinations of Quinine and Diluted Nitro-hydrochloric Acid, are to be resorted to. Moderately active exercise in the open-air when exercise is possible, and *urine* walking is difficult, the patient should be carried out to sit or recline in the sunshine, or be pushed in a bath-chair. Where these are impossible, as in the middle of winter, indoor exercise and general massage may be tried, and the appetite coaxed in other ways, as by unusual variety of choice and carefully-cooked foods administered often.

When digestion shows signs of failing Pepsin Wine may be freely given after every meal, or a little Alcoholic stimulant may be permitted. Food should be peptonised, and all enemata must be partially digested before administration. (See page 311.) 12

bad cases the patient should be roused up at least once during the night to receive nourishment, and in the case of children this must be done oftener.

The writer has seen a patient almost completely paralysed after diphtheria, in which swallowing even of liquids was altogether impossible. Standing was out of the question, the patient being unable to turn in bed, and respiration threatened to stop from respiratory paralysis. Recovery ensued in this apparently hopeless case by rectal feeding with peptonised beef tea, milk and eggs, and inunction of Cod Liver Oil and the application of the cod liver oil bandage already described (page 578).

Drugs are useful but before referring to their internal administration it must be emphasised that they hold a secondary place in comparison with the importance of feeding.

Iron is the most reliable. It may be given at any stage of the affection, and in any form which the peculiarities of the case suggest. It appears to do best in those cases where it was not freely administered during the progress of the primary affection. The dialysed preparation appears to act better than any other, especially as it is much less likely in large doses to interfere with the digestion or bowels. Some authorities strongly recommend the various natural iron waters, and when combined in the form of an effervescent mixture they agree when the dialysed liquor or the favourite carbonate or saccharated carbonate is not relished. Small doses should be tried when large or full quantities disagree. Blanchard's pill of the iodide of iron may be administered for long periods without giving rise to unpleasant results.

Arsenic is sometimes useful, but it is only indicated in very tedious cases, and then when combined with Iron.

Strychnine or Nux Vomica is a remedy of great value, but it should not be given in the acute stages of paralysis. In the later stages it may be given by the mouth or in very chronic cases it may be injected with much benefit into the weakened muscles.

The following is a good routine formula for internal administration.—

R. *Strychninæ* *gr. iss.*
 Tinct. Ferri Perchlor. *ʒiv.*
 Quinnæ Hydrochlor. *gr. xxxv.*
 Glycerini Purificati *ʒj.*
 Aquæ Destillatæ ad *ʒiv. misc.*

Fiat mistura. Capiat ʒj. ter in die post cibos ex aqua.

Electricity is open to the same objection as Strychnine—i.e., that in whatever form administered it may do harm in the early stages. At a later period its value cannot be doubted and in a very chronic case the writer found that improvement ceased as

ten minutes once daily. (5) Static e

Where the paralysis has resisted muscles continue to waste, massage times a day, and stimulating embroc been advised. The Clullu Paste co is an excellent local application, a paste composed of—

R. *Pulv. Zingibers*
 Pulv. Sinapis *℥ii*
 Adipis Preparati

With this paste circular bands of 1 breadth are smeared, and applied at to the whole length of the limb & changing the position of the bands it may be kept in a state of continuous the partial subsidence of the irritati injection of small doses of Strychni speedy recovery.

For the bulbar crises, which com during the third week of apparently and which are nearly always fatal, lit symptoms as they arise. Strychnine may be tried.

PARALYSIS OF FACIAL AND under Paralysis, Peripheral.

PARALYSIS, Infantile (Poliomye

Where the physician is fortunate a

Saline purge following a moderate dose of Calomel should be tried, and afterwards Iodide of Potassium in moderately large doses may be given. Belladonna and Ergot are credited with arresting the myelitis when given early.

Most cases, however, do not come under observation until the paralysis has been thoroughly established for a variable time, and, as the remedy to be relied upon in the treatment of infantile paralysis is Electricity, the question at once crops up—What is the earliest period at which the use of this agent is justifiable? Gowers advises the end of the third or fourth week the writer has with benefit applied a weak current earlier. The current has no effect upon the cord but upon the muscles, which rapidly suffer from degeneration of their nerve fibres. When nerve cells and fibres are *destroyed* the agent can be of no use, but where only damage has occurred it is most valuable. It only acts by its influence on the muscular tissue, and only voltaic electricity can stimulate this tissue. The Faradic current only causes pain and irritation, and the paralysed muscles do not respond to it, the muscles which respond to it, however, will improve by it. It is a serious mistake to use either current in the acute stage before the spinal mischief has ceased to extend.

The best method consists in galvanising the affected muscles by placing the anode on the spine or upper part of the muscle, whilst the kathode is passed over the muscles, contact being made and broken frequently by a gentle stroking process 40 to 60 times per minute. At first a few minutes daily, gradually extending to 10 or 15 minutes daily for many weeks may be carried out. Excellent results follow even when this treatment has been delayed for many months, and some authorities have reported great improvement even after 12 months, but the greatest perseverance and patience must be exercised, and the current must not be strong. Gowers advises as many cells to be gradually used as will cause the affected muscles to swell up in slight contraction as soon as the sponge is placed upon the skin. He only acts on those muscles in which Faradic irritability is lost or lowered. The others recover perfectly without stimulation. At a later stage the continuous may be suspended for the Faradic current from time to time, and this applies also to the treatment of the chronic form of atrophic paralysis as well as to the acute, whether occurring in children or adults. The electrical treatment must be kept up when necessary daily for a couple of years.

As soon in the case as electricity is indicated, Strychnine may be commenced in small doses, and steadily increased till 3 mins. of the B.P. Liquor may be given twice daily to a child 3 years old for short periods. At a later stage it may be given by deep injections into the paralysed muscles.

Massage of the affected limb is of the greatest service. The nurse or mother of the child can be easily taught to carry this out several times a day by pinching up and rolling the affected

muscles between her middle finger and thumb, and the writer has obtained excellent results by rubbing in Cod Liver Oil at the same time; in this way much may be done to prevent deformities. Stimulating applications, as the Liniment of Camphor Chilli Paste or the Paste of Rose Coemack mentioned under Paralysis, Diphtheritic, may be also used; and local brine baths, or sea bathing and hydropathy, are very useful. Tonics as Quinine, Iron, Arsenic, Cod Liver Oil, and Malt Extracts, with change of scene and plenty of good food and fresh air, are essential. Contractions of unopposed muscles must be met by appropriate orthopaedic measures and gymnastics. When these measures are skilfully carried out, deformity may be entirely prevented, and often, if already established, it may be fairly corrected. Thus the application of braces taking the place of paralysed muscles may entirely prevent the deformity caused by the sound muscles acting without any opposition. If deformity has already existed, tenotomy of the contracted tendons is useless save as a preliminary in the adjustment of a properly devised splint or brace. Starr states that he has seen much benefit from the recent plan of splitting the tendons of the healthy muscles, and attaching them to the severed tendons of paralysed ones, so that the healthy muscle is made to do the work of the paralysed one—for example, where a portion of the tendon of the post-tibial muscle was attached to the tendon of the peroneus longus. Spinal curvature should be prevented by keeping the child in the horizontal position till the back muscles recover their power.

PARALYSIS, General, of the Insane.

The first step in treatment should be to send the patient from his own home to a proper asylum where he shall have complete rest and isolation from near relatives, a generous diet, excluding much animal food and alcohol, warm clothing, a moderate supply of tobacco, and such drugs as will ensure calm sleep without previous excitement. The drug treatment of this disease ends always in failure, there is no known agent which will in any way modify the surely fatal issue. But when a distinct history of syphilis is present, Mercurial inunction may be tried, though there is as little hope of this being beneficial as there is in tabes. Various symptoms as they arise will call for attention: thus the bladder may require irrigation, convulsions may indicate Bromides, bed sores may demand preventive and curative remedies. Talc recommends severe blistering of the head and neck, kept up for many weeks in the early stages of the disease.

A study of the pathology of the affection has led to attempts at reducing intra-cranial pressure and trephining, and drainage of the subarachnoid space in a few cases has given good results but the difficulty of keeping up a continuous and permanent drainage without the risk of sepsis has prevented the operation being often done. Notwithstanding a few comparative successes, the surgical

treatment of this affection is now almost considered to be unjustifiable.

Savage, believing that the disease is the direct result of the action of some unknown toxic agent on the nerve centres, is not without hope that an antitoxin will be discovered which will meet the case. Robertson is satisfied that this toxin is of gastro-intestinal origin, and is the result of failure of the natural immunity caused by exhaustion of the leucoblastic function of the bone marrow. He believes that the future successful treatment of the disease will lie in measures which will check the excessive growth of the gastro-intestinal bacteria.

PARALYSIS, LANDRY'S.

The treatment of this malady will be that of Myelitis, which see on page 583.

PARALYSIS, LEAD—See under Plumbism.

PARALYSIS, Peripheral.

Under this heading may be included all cases of local paralysis not depending upon disease of the spinal cord or brain; it includes paralysis of spinal as well as of cerebral nerves. The chief indication for treatment will be, in the first instance, found in the removal of the cause, when this is possible. Diligent search should be made in every case for any compression upon the nerve in its course. Tumours of various kinds and abscesses may by pressing upon the nerve trunks, produce both sensory and motor paralysis, and in such cases removal of the cause must be accomplished before any improvement can be expected. Reflex causes, as carious teeth, are to be treated upon similar principles. Blows, over-excitation exposure to cold and damp, and other common causes will also afford obvious indications for treatment.

The routine management of the paralysis is such as has been already mentioned under Diphtheritic Paralysis, *i.e.* —

Counter-irritation to the nerve trunk and entire limb, Massage applied to the affected muscles, Strychnine hypodermically in the later stages of the affection. Electricity—using the form of current which is found to most easily produce muscular contractions in the affected limb.

The most suitable method for the majority of cases will be found in placing the anode over the nerve trunk, on the skin above the lesion or over some indifferent part, and applying the kathode over the motor points as contact is rapidly made and broken. The "labile" method may be used with great advantage by placing the anode over an indifferent part, as the kathode is slowly moved over the skin covering the affected muscles and nerves, or the "stable" method may be tried. Large moistened sponge electrodes should be used. In any case the Faradic current

After dressing or dusting, the absorbent cotton wool is to be applied and kept in its place by a bandage. A large saline purgative having been administered, the following mixture should be commenced. —

R. Potassii Iodidi
Potassii Bromidi
Syrupi Aurantii
Aqua Camphora

Fiat mistura. Capiat ʒss. ter id

This may be continued during affection.

There is much difference of opinion as to the form of electrical treatment is to be continued (the form of electricity best suited for the purpose that the best results are obtained in the first week). He bases his conclusions on a series of cases, but of one of these he was very much satisfied from a severe attack after 1872. Gowers is very doubtful if it is of any use and he is satisfied that electricity has no great good in improving the nutritive condition of the muscles. He places the positive electrode on the muscles with the negative on the chorda tympani and the filaments of the palate muscles, it is shown that the

of the nerve in the face. He has injected $\frac{1}{10}$ grain, beginning with 2 or 3 minims daily of the B.P. Liquor.

Perchloride of Mercury in small doses is indicated after the Iodide has had a good trial, and where there is any reason to suspect syphilis it may be administered from the beginning.

Where the paralysis is the result of middle ear disease, this condition will require radical treatment before the use of any of the previously mentioned agents is permitted.

Paralysis of the third, fourth, or sixth nerves (peripheral) depends in the great majority of cases on syphilis, or other toxic agent, and it is to be treated upon the same principles—viz., Leeches and blisters behind the ear or over the temple, large doses of Iodide of Potassium, and Mercury. Galvanism is also useful, and may be employed by passing a very weak continuous current through the eye-ball and brain by placing the anode over the occiput and the kathode over the closed eye-lid.

PARALYSIS from PROGRESSIVE MUSCULAR ATROPHY or WASTING PALSY.

The remarks made under the head of Infantile Paralysis apply to the treatment of the present affection. Any benefit to be expected can only be obtained by Electricity, and this may be applied in the same manner as for Infantile and Diphtheritic Paralysis (which see), and from hypodermic doses of Strychnine. The writer has satisfied himself that in one case this agent arrested the disease for a long period, but the doses usually recommended are useless. 5 minims of the B.P. Liquor daily in one injection is a very moderate dose; this corresponds to nearly $\frac{1}{10}$ gr. The usual nerve remedies may, however, have a fair trial—Arsenic, Phosphorus Chloride of Gold, and Iodides can do no harm and they may be given with Cod Liver Oil. Where a syphilitic history is clear, good may be obtained from large doses of the iodide in combination with small quantities of the perchloride.

The general health is to be maintained in the highest state of perfection, and great care should be bestowed upon the clothing, the patient being well encased in flannels, and if the affection is vigorously and persistently treated by galvanism and strychnine from the early stages, there is a fair prospect of some improvement, or retardation of the end.

These remarks also apply to Bulbar paralysis, also known as Glosso-labio-laryngeal paralysis, which may be regarded as the prolongation upwards of the progressive muscular atrophy lesion into the medulla. Feeding becomes very difficult, and towards the close of the disease dangerous. Soft puddings and blancmange are more easily managed than liquids, in some cases a soft rubber tube must be used for liquids. In using electricity the positive pole should be placed over the nucha, and the negative applied to the affected muscles.

These means fail, which should be seldom, except in cases where there is no use in waiting to apply ice, but after this, the taxis may be again tried, and if reduction is not effected, the surgeon looks for the site of constriction, and divides it with a sharp-pointed curved bistoury, taking care to make his incision close to the glans *behind* the collar of swollen prepuce and not in front of it, as the appearance of the parts suggest. The glans should be forcibly depressed by the tip of the thumb as the incision is being made, and as the narrow orifice is divided, reduction is easily accomplished.

APLEGIA—See under *Myelitis* (Page 584).

ONYCHIA—See *Onychia* (Page 619).

OTITIS—See *Mumps* (Page 582).

PEDICULI.

The destruction of these parasites often gives considerable trouble, and to effectually banish them some knowledge of their habits is essential. Thus, the ordinary body louse is seldom seen upon the skin, and as it resides in the seams and creases of the clothing it cannot be destroyed until the garments are subjected to the action of heat or re-agents which kill the parasite. It must also be kept in mind that agents which are destructive to the pediculi may have no effect upon their ova; and since these are not hatched till after the expiration of nine or ten days, the case cannot be regarded as cured till after this period has elapsed. After the total destruction of the parasites and their ova it may be sometimes necessary to treat the eczema or other lesions to which their presence has given origin.

Pediculi Capitis.—In mild cases which have not been long neglected there is no necessity to cut or shave the hair, but in hospital this must often be done, and when once thoroughly accomplished there is no trouble afterwards, as the ova are also removed adhering to the hair. Shaving is, however, almost impossible owing to the numerous crusts and scabs. Close clipping by sharp scissors answers every purpose, and a good washing with soft soap completes the destruction of any straggling vermin or adhering ova.

In ordinary cases a remedy should be prescribed which, though capable of destroying the pediculi rapidly, should not be of such a nature as to injure the patient, even if injudiciously applied. This is a matter of vital importance in large charity or other schools, where mercurial preparations should not be used. The favourite, old-fashioned remedy is a safe one—viz., the Ointment of Stavesacre B.P. This, when rubbed into the roots of the hair or used as a pomade, effectually destroys the lice, but does not reach the ova contained in the nits. If the application be continued for a

found that the *pediculus corporis* children's clothing. He has known extensively used as an ordinary hair comb causing any irritation whatever.

In cases where a rapid effect is desired are entrusted with the management of the hospital, a weak solution of Potassium employed, but one of the best of all is of the Ammonio-Chloride of Mercury 10, as it not only destroys the parasite eczema or impetigo which has resulted from irritation caused by its presence. When a skin affection present, petroleum should be used.

For the treatment of the nits or eggs, soaked in Methylated Spirit after which Vinegar or Solution of Borax may be used. A very fine comb easily clears the hair of the nits.

Many other agents are employed such as Tobacco and *Cocculus Indicus*, Chloroform, Peppermint, Cajuput, Anise or Clove Leaves, Quassia, Pellitory, Creolin, &c. These are all more commonly used than the others.

Shoemaker adopts the excellent plan of using a soap, and his Corrosive soaps are elegant and effective remedies.

The objectionable odour of paraffin is removed by mixing it into an ointment or pomade with some Balsam of Peru.

Pediculi Corporis are to be abolished by the use of the following effective method of dealing with them.

the clothes were immediately put on again. The White Precipitate Ointment may be smeared over the shoulders and armpits; and if it does not speedily cure the accompanying eczema or prurigo, other measures, such as Alkaline baths andunctions of Olive Oil, may be prescribed.

Pediculi Pubis or *Crab Lice* may prove very difficult to eradicate, especially when the parasite infests the various regions of the body in hairy men. When confined to the pubes a few applications of strong Carbolic Lotion (1 in 20) may destroy them, but the eggs are not likely to be affected by this. The writer has seen them effectually abolished by painting the parts once with the Glycerin of Carbolic Acid, but this is a severe remedy, and only applicable where the parasite is limited to a small area. Solution of Corrosive Sublimate (2 grs. to 1 oz.) may be freely applied where the beard, whiskers, eye-brows, or chest are affected. The most manageable application, however, is an Ointment of White Precipitate (25 or 30 grs. to 1 oz. Lard). This may be frequently smeared over the affected regions without any danger of salivation, and if a little Paraffin Oil be added a most efficacious parasiticide may be obtained.

 Bals. Peruviani ℥i.
 Lanolini ad ℥j. *misce.*

Fiat Unguentum.

A 5 per cent. Calomel Ointment is also generally efficacious, and Bernbeek advises a bath of 4 drachms of Corrosive Sublimate in 30 gallons of water as a remedy for all pediculi. Of all the mercurial preparations, the speediest and at the same time the safest is that of Brocq. He uses a solution of 1 grain of Corrosive Sublimate dissolved in 1 oz. Vinegar, and states that this kills both the parasites and their ova at the same time.

The common practice of rubbing in the strong mercurial ointment over extensive regions of skin is objectionable and dangerous. Iodoform Ointment, or even the application of iodoform gauze, is often effective. Chloroform destroys both the parasite and ova by one thorough application, but it is liable to cause serious cutaneous inflammation or irritation. Ether spray is efficacious, and very much less irritating, and it may be applied over any large tract, as over the front of the chest and pubes, without danger.

PELVIC ABSCESS.

The treatment will be in the early stages the same as for any deep-seated inflammation or abscess (see under Abscess). Thus, rest, Opium, leeching, hot fomentations, poultices, enemata or

be employed, such as a little warm water bottles to the feet, but at this possible unless the affection supervenes which had previously suggested the supervening. As the symptoms and they are to be dealt with upon general rest in the horizontal position is to be exclusively milk, or liquids such as water. The bowels should be clear and a Saline purgative may be of value or saline purgatives at the be- nations cannot be doubted, and if p of Calomel the results are very good observers the disease may be abated if leeching and the ice-bag be used.

The fact that nearly every case a septic origin must not be lost sight physician to search for the cause the vagina or about the os, abrasions instruments, &c., may be the cause. serious issues which can be put before the face of an acute pelvic cellulitis opening up of the cervix and curett with the view of removing the focus the time the symptoms appear to w has travelled beyond the infected em

The antiseptic vaginal douche should and if a little Condy's fluid be added necessary as an antiseptic is obtained

The water should be as hot as can gallons may be used at a time, the

syringing. The best application will be a large piece of spongopiline squeezed out of very hot water, and sprinkled with Laudanum, and bound moderately tight by means of a calico binder. This can be worn continuously, and will not be interfered with by the syringing. As a rule, the warm applications having been commenced are to be kept up constantly till the termination of the inflammatory action.

Pain is to be subdued by small doses of Opium often repeated. It is a good plan to begin with a pill containing 2 grs. of powdered opium, and to keep up the effect by giving $\frac{1}{2}$ gr. every two, three, or four hours, according to the severity of the symptoms. Any simple diuretic combination may be given if the skin keeps dry and hot, or the opium may be prescribed in the form of Dover's Powder. The general consensus of opinion is decidedly against the old plan of dosing the patient with large quantities of opium.

Antipyretics proper are not indicated in the very early stages, but any time that the temperature runs up to 104° or more, 10 or 15 grs. of Quinine or Antipyrine may be administered and repeated when necessary.

Leeching is the best form of blood-letting admissible, and many authorities recommend a dozen or more leeches to be applied over the skin above the groins, about the anus, perineum or even to the vagina or cervix. The cervix may be freely scarified through the speculum, and the oozing kept up by the warm douche.

Quinine is indicated in most cases, and 4 grains with $\frac{1}{2}$ grain of the watery extract of opium may be given every three or four hours. Iron may be useful in such cases if it agrees with the state of the digestive organs.

Mercury is liable to be given too freely in pelvic cellulitis. It is of most unquestionable value in the opinion of the writer, but salivation is to be deplored. It is never necessary to touch the gums, nor does it appear to be good practice to exhibit the drug until after the appearance of the dense solid exudation has been evident for some time. When given in small doses it hastens resolution. From a limited experience, which does not, however, justify the writer in drawing a general conclusion, he is led to suspect that the drug if given too early, is liable to favour suppuration, but if withheld till the fluid part of the exudation has become absorbed, it gives a better chance of satisfactory resolution, and it gives best results when combined with quinine and opium, as in the following —

R. *Hydrarg. Subchloridi* gr. ss.
 Quinnina Sulphatis gr. iiss.
 Extracti Opii Aquos. gr. ss. *misce.*

Fiat pilula. Mille tales xvij. Sumat unam ter in die.

Iodide of Potassium is very useful at a still later stage, and may be given safely in doses of 10 to 15 grains even when smaller doses cannot be tolerated.

Complications must be met as they arise. Thus vomiting is best relieved by ice and a simple Saline or effervescent mixture containing a little Hydrocyanic Acid, whilst counter-irritation by a large sinapism applied over the abdomen is also useful.

Diarrhœa should not be checked, especially if the motions are very decidedly offensive. The writer has observed this in severe cases where pus had formed, and he is inclined to regard it as a valuable sign of the absorption or infection of the system when rigors fail to warn. It is an indication for large doses of quinine and stimulants, and for the suspension of mercury or iodides and the continuation of poultices and hot vaginal douches tinged with a little Cond's Fluid.

Sleeplessness is best met by Sulphonal, and not by increased doses of the Opiate. In chronic cases resolution may be hastened by counter-irritation with strong Linniment of Iodine or sinapisms, and at a very late stage, long after the subsidence of the inflammatory action by Massage and the use of the continuous current (50 to 80 milliamperes), with one pole in the vagina and the other over the pubes.

When, in spite of the above measures, the inflammatory exudation softens and suppuration occurs, the case becomes one of pelvic abscess, poulticing must be continued, and the diet increased to the fullest extent of the digestive powers of the patient, strong soups and beef essences being freely administered. Pointing must be watched for anxiously. Speaking generally one may say that at this stage the less interference or the fewer examinations the better. In the vast majority of cases, the slower the process by which the matter travels in the direction of the least resistance the safer for the patient. Where the abscess points towards the surface there can be little if any danger in waiting, and if opened too early, owing to the rigid state of its infiltrated walls, it does not readily collapse, and air easily enters. But as a rule the presence of pus must call for its speedy evacuation. Afterwards the cavity should be gently washed out daily with warm solution of Boracic Acid, very weak Perchloride of Mercury Solution, or Cond's Fluid, but irritating substances like iodine, or chlorinated liquids are not to be employed. A large pad of iodoform gauze may be placed over the opening, or if the discharge is very free, carbolie tow or teased oakum may be selected.

When the matter bulges into the floor of the pelvis, and is felt in the rectum or vagina, the question of making an opening or leaving the case to nature is to be speedily decided. Aspiration is out of the question. One of two courses may be determined upon—viz., either to plunge in a bistoury and evacuate the abscess at

the most prominent part in the vagina or rectum, or else to thrust in a large curved trochar and canula, driving the canula home after the trochar has been removed, as described under the treatment of Hæmatocele. In either case the largest sized drainage tube should be inserted through the opening made by the bistoury or through the canula, when in position before being withdrawn, and the vagina filled with gauze. Through the drainage tube the abscess cavity may be frequently washed out by a warm Solution of Boracic Acid or other mild unirritating antiseptic once or twice daily.

If the surgeon can satisfy himself that the abscess is not bulging towards the peritoneal cavity, but is pointing in the one safe direction—*i.e.*, towards the vagina or rectum—interference is unnecessary, but it is not often that one can satisfy himself upon this point, and where there are reasons to suspect that to wait for the discharge of the abscess through the vaginal wall would be to incur the risk of its bursting into the peritoneal cavity, incision should be made at once.

When the evidence is clear that the abscess has burst into the peritoneum there still may remain much to be done, as a fatal issue is almost certain if the case be left alone, and it will become then a question of the advisability of performing abdominal section. Most authorities boldly advocate the opening of the abdomen in every case where suppuration has occurred without waiting for the danger of bursting in those cases which cannot be reached from the vagina. It will often be necessary to do this in chronic cases where pus has collected in the tubes, and then the operation becomes one for the removal of the uterine appendages, but this may often be accomplished by the vaginal section.

The horizontal position and rest are to be maintained for several weeks after apparent recovery. Where drainage is being carried out the patient may be placed in such a position as to ensure the most complete evacuation of all discharges.

In the stage of convalescence, tonics change of air, Iron, Cod Liver Oil, Syrup of the Phosphates, with peptonised foods and malt extracts, are useful.

The method of treating parametritis, and perimetritis with old pelvic exudations, by continuous pressure, exerted by filling an appliance with small shot or metallic mercury and passing it into the vagina, has been tried by Freund and others. Counter-pressure is kept up by a weight of 2 or 3 pounds of small shot placed on the hypogastrium. The plan is still on its trial.

PELVIC HÆMATOCELE—See Hæmatocele, Pelvic (Page 349).

PELVIC PERITONITIS.

The treatment of this affection will be best carried out by adhering to the principles just laid down for the management of pelvic cellulitis, from which it often cannot be distinguished. In

in endometritis go on to pelvic cellulitis. It is often the result of a gonorrhoea up to the tubes. Hence the local inflammation or pelvic cellulitis.

Absolute rest, Opium, warm foot-baths, leeching may be indicated. When tolerated Leiter's tubes, cold compresses, and Antipyretics may be given. Fever may be present to an extent that threatens patient's chances of life, and antipyretics should be given at the very commencement. Upon the organs are in good condition, and the fever is very high, the safest and most efficient remedy is to administer Quinine in combination with Iron, 5 grains may be given daily in a tincture diluted with 2 oz. water. If there are obvious septic causes at work, rapidly mounts high, as in cases of puerperal fever, Antipyrene (15 grs.), Antifebrile Sodium (30 grs.) may be given at intervals. When the abscess is most likely to occur, the same rules are to guide the surgeon. If the pelvic cellulitis was under treatment.

Saline purgatives, which are so effective in pelvic cellulitis, may be employed. The bowels for two or three weeks is common in ordinary cases. In all cases of this kind, if given by the mouth, there can be no harm about the safest drug. Castor Oil is the safest.

PEMPHIGUS.

In a disease presenting much of the

through our ignorance of pathology or etiology it is customary to advise that every other departure from health is to be sought for and remedied as far as possible by improved hygienic surroundings, altered diet drugs, change of habits, scene, &c.

Of drugs for the treatment of pemphigus there is one which, though it sometimes fails utterly, nevertheless in many cases appears to exert a specific influence, and it should always be administered freely and for a considerable period. Arsenic should be prescribed as soon as the temperature becomes normal in acute cases, and at all stages of the chronic varieties of the disease. It is, however, of little use in the foliaceous form. The dose of 3 minims of Fowler's Solution should be rapidly increased to 6, and afterwards to 9 minims three or four times a day, immediately after meals, and though some patients may be met with in whom 15 minim doses may be tolerated for long periods, it is a good practice not to venture beyond three doses of 10 minims each in the 24 hours. It is needless to say that it should be well diluted before administration. In chronic cases the arsenic should be combined with Iron. Cod Liver Oil and Quinine are also both of some value in the foliaceous form of the disease. The cod liver oil may be given in table-spoonful doses of the Kepler Extract preparation, immediately before or after a mixture containing 7 or 8 minims of Fowler's Solution and twice as much Tincture of Iron.

Where arsenic, after an honest trial, fails, Chlorate of Potassium in large doses may get a good trial—it has succeeded in some cases. Anderson, however, recommends the hypodermic injection of arsenic when it fails by the mouth, and he even combines Quinine with it. The new arsenical preparation—Cacodylate of Soda—may be given in $\frac{1}{2}$ gr. doses with advantage by the hypodermic method.

Iodide of Sodium in full doses (5 to 15 grains) may also get a trial. Belladonna, Guaiacum, Phosphorus, Antimony, and even Mercurials have been recommended, but unless when arsenic has completely failed in the foliaceous form their administration is not worth a trial.

In pemphigus vegetans, Pollock and Hutchinson advise an early resort to Opium in full doses. This rare variety is always fatal.

Local treatment will depend upon the stage of the affection. In acute cases, characterised by great tension in the bullæ, these may be pricked with a sterilised needle or lancet and dressed with Zinc Ointment or any bland unirritating salve. Powders freely dusted over the weeping surface are in some cases better, especially when excoriations are present. Amongst dry applications of this sort are finely-powdered Fuller's Earth, Oxide of Zinc, Chalk, Starch, Prepared Camphine, Oleate of Zinc, &c., either alone or mixed in such proportions as the appearance of the parts indicates.

Unna's Paste is a convenient and grateful preparation. It can be prescribed by ordering—

R *Cresolæ Preparata*
 Zinci Oxide
 Olei Lini
 Liquoris Calcis ana ʒi. misc.

Lotions are sometimes preferable to either ointments or powder, and Secretan has most successfully treated pemphigus pruriginosus by continuous applications of compresses soaked in a 1 per cent. solution of Carbolic Acid. This effectually relieves itching and hastens healing.

The writer has used the ordinary Carron Oil, to which 1 or 2 per cent. of Carbolic Acid is added for chronic cases. Cripps reports success from the application of the Oleate of Mercury.

In very tedious cases of the foliaceous variety the physician will feel his resources taxed, and the best plan is to permit the patient to lie in the tepid bath for several hours daily after which the excoriations may be dressed with Zinc Ointment to which 5 or 10 grains of Calomel per oz may be added. 2 or 3 drachms of Corrosive Sublimate may be added to 30 gallons of water as a Mercurial bath, but the patient should not rest in this for any considerable length of time.

Baths are fitted up in which the patient can eat and sleep and Kaposi has found these of the greatest benefit in very chronic cases associated with much prurigo or itching. Bran, Gelatin, Carbolic Acid, or Tar may be added to them. In one very obstinate case of foliaceous pemphigus the writer obtained considerable benefit by the use of the continuous current, but the patient left hospital before the treatment was completed.

Where the mucous membrane of the mouth is affected, the constant use of the Glycerin of Borax, gargles of Chlorate of Potassium, or tablets of the Chlorate with Borax are the best local applications.

PERFORATING ULCER OF THE FOOT.

The treatment of this affection is at the best unsatisfactory and tedious, as it is almost always associated with some nerve lesion, like tabes, or spina bifida. The cause should receive careful attention, and complete and permanent healing of the ulcer may be expected in a percentage of cases. The advice given by surgeons who are apt to recommend amputation of the foot should not be seriously entertained till the failure of medical treatment has been demonstrated. In one case which the writer saw with Dr. Wales, permanent healing occurred after the use of the continuous current. This was applied in various ways for

several months, chiefly by dropping one pole into a foot-bath of tepid water, whilst the other pole was applied to the sciatic region, or held in the hand.

The remedies suitable to the treatment of the primary lesion should be steadily persevered in at the same time, and the anæsthesia soon begins to get less and less. In *tabes dorsalis*, Chloride of Gold, Arsenic, Iodide of Sodium, Antipyrine, and Phosphorus should have a fair trial, but it is upon Electricity that dependence is to be placed. The ulcer may be dressed by any stimulating ointment, as the *Unguentum Resinæ*, or by very weak Nitric Acid, Perchloride of Mercury Solution, or Spirit Lotion, by means of a piece of lint covered with tinfoil or thin sheet lead. Chipault, of Paris, reports striking success in 25 cases treated by stretching the posterior tibial and plantar nerves.

When diseased bone is present, it should be removed by the gouge or forceps, and if the wound is very sluggish it may be occasionally brushed over with a strong solution of Nitrate of Silver, or touched with strongest Nitric Acid, or Acid Nitrate of Mercury Solution, or even brought into light contact with the thermo-cautery, or scraped thoroughly with a Volkmann's spoon; the thickened cuticle round the edge of the ulcer should be frequently pared by a sharp scalpel or corn knife. When all these measures fail, a Syme's or a Teale's amputation may then be seriously considered, but the incisions must be made above the level of any anæsthesia which may be present.

PERFORATION of STOMACH and BOWELS—See under Gastric Ulcer, Peritonitis (Perforative), and Typhoid Fever.

PERICARDIUM, Dropsy of.

In the majority of cases this will yield to active treatment, directed against the cause of the hydropericardium. Thus, if it be part of the general anasarca of Bright's disease, the best measures will be diaphoretics (hot vapour baths) diuretics (*Digitalis*), and cathartics (Sulphate of Magnesia). Where the fluid remains stationary or continues to increase, there is nothing left but to tap or aspirate the pericardial sac.

This is not an operation to be undertaken without an accurate knowledge of the anatomical structures in the front of the thoracic cavity.

After mapping out the area of dulness, and ascertaining, as far as possible, the limits of the heart, as the patient lies upon his back with his shoulders raised, a fine hypodermic needle may be inserted and some fluid withdrawn in order to verify the diagnosis.

The needle puncture may be made almost anywhere, but it is better to make it in the same spot into which the aspirator trochar or needle is to be afterwards inserted. This spot is of importance;

it must be near to the sternum, and the left is the side generally selected. Some surgeons go close to the sternal margin, ~~and~~ advise keeping one inch, and some recommend the puncture to be made two and a half inches from the margin of the bone in order to avoid the internal mammary artery. The fourth or fifth interspace is the best, though the sixth or seventh may be selected in some cases.

The operation may be successfully performed by perforating the fourth or fifth space upon the right side, though upon the whole it would appear that the left fifth interspace close to the sternum is the best, though either side may be selected.

The needle should be inserted upwards and slightly inwards, as to avoid the heart, and the fluid must be very slowly withdrawn. It is a good plan to detach the aspirator, and keep the end of the tube under a little carbolic lotion, whilst by a syphon action the cavity is slowly emptied. An ordinary hydrocele trocar and canula has been used, but the aspirator needle is better. The needle should be kept steady whilst the fluid is being withdrawn, though it does not appear that pricking of the ventricular wall is of necessity a serious mishap. Wheelhouse inserts the trocar on the upper surface of the fourth rib to the left of the sternum and advancing it steadily upwards from left to right, until no cardiac impulse can be felt withdraws it, leaving the canula in position. Porter's recent operation will be described presently.

Should the fluid be found to be purulent, the tapping will probably require repetition, and though the treatment in this case should be detailed under the head of Pericarditis, it may be mentioned here for convenience. Drainage of the sac will be essential. The passage of a fine drainage tube through the canula or needle would meet all the requirements of the case, but this will generally be found impracticable owing to the narrowness of the canula, hence an opening must be made with a sharp scalpel or bistoury. The best site for the incision will be that of the previous puncture.

The incision should be made as recommended by Chiropo the tissues being incised layer by layer for a distance of three or four centimetres (rather more than one inch), taking care to avoid the internal mammary artery, which may if necessary, be drawn inwards. The exposed pericardium may then be caught up by forceps and opened by means of a guarded bistoury. Antiseptic precautions should be taken both in the tapping as well as in the cutting operation. The greatest care must be exercised should irrigation be deemed necessary though such a procedure is not desirable, and irritating antiseptics must not be employed. If considered absolutely necessary, a little warmed Boracic Acid or Permanganate of Potassium Solution may be used.

Porter has quite recently published a series of brilliant results from his method of dealing with suppurative pericarditis. He maintains that the fifth costal cartilage on the left side should

always be removed in order to expose and properly drain the sac. He maintains that the operation is a much less dangerous proceeding than simple aspiration, it is easily done, and local anesthesia is all that is necessary in many cases and he urges that it should always be done in simple serous effusion in preference to aspiration. He gives a list of 51 cases operated on by this method, they were for the most part purulent, and 20 recovered. In Pneumopericardium aspiration or the excision of the costal cartilage and free incision might be necessary.

PERICARDITIS.

The diseased condition which has led to the inflammation of the pericardium will demand treatment, and in many cases this is all that is necessary, and as the affection is commonly a complication of or sequel to acute rheumatism, the reader will find the antirheumatic treatment under the heading of Rheumatism. The special treatment will be almost identical with that of Endocarditis, which see upon page 370. The following is a brief enumeration of the remedies indicated—Absolute rest in the horizontal position, poulticing, leeching, blisters, or milder counter-irritation, Opium to relieve pain, Digitalis and Strychnine at a later stage to strengthen the heart, and at a still later stage small doses of Mercury are useful. Before resorting to tapping, further measures may be pushed with the view of causing the absorption of the effused liquid. Thus a series of very small blisters may be applied over the cardiac area after the subsidence of the inflammation. Iodine may be applied, and some recommend that Mercurial Ointment be rubbed in over the sac. Diuretics and purgatives are, as a rule, useless, but large doses of Sodium Iodide should get a fair trial. When pericarditis occurs as a complication of pleuritis or pneumonia, in addition to the employment of the above agents the remedies indicated for these diseases must be pushed. When it occurs in connection with septic conditions or ulcerative endocarditis, active supporting measures must be resorted to as extra feeding, stimulants, Sulphocarbolates in large doses (25 to 30 grains), Quinine to the extent of inducing cinchonism, and Iron in full doses.

When the amount of fluid is so large as to threaten life the pericardium may be incised or tapped with a fine aspirator needle and when suppuration has occurred, provided the primary lesion is not necessarily a fatal one, life may be saved by opening and draining the pericardial sac. (See Porter's operation at the end of the preceding article.)

PERIHEPATITIS

Is generally an accompaniment of peritonitis, of hepatitis, or cirrhosis, or even of cancer of the liver, and its treatment will consist in the exhibition of the remedies suited to these different affections, whilst pain is relieved by Opium or Morphia internally,

and poultices, blisters, counter-irritants, leeches, or local anodynes externally. In universal perinephritis the chronic peritonitis accompanying it generally calls for tapping.

PERINEPHRITIS.

Pain must be relieved by hot linseed poultices, warm fomentations, or mild counter-irritants, and some still believe that leeching or wet cupping and the free application of the Lament of Ilium if applied early, may prevent suppuration in the phlegmonous stage of the disease.

Of internal remedies, tonics, such as Quinine and large doses of Iron may be prescribed, but these cannot be expected to do more than improve the general health and no law can be laid down except that remedies are to be used to combat symptoms as they arise.

Boric Acid in 10 grain doses may be given where calculus pyelitis is the primary lesion, but it generally disagrees.

As matter forms, a free incision should be made with a sharp bistoury over the softest spot in the lumbar region posteriorly, skin, fascia, and muscles being divided under strictest aseptic precautions, and the finger inserted and caudal, if present removed after a thorough digital examination of the kidney. A large drainage tube should be inserted after the evacuation of abscess and sloughs. The usual mistake is to wait too long before incising. All authorities agree that in the face of urgent symptoms with local oedema and doughiness the surgeon should not wait for fluctuation, but immediately make his lumbar incision.

PERINEUM, Fistula of.—See under Urinary Fistula.

PERINEUM, Rupture of.

The prevention of this complication at delivery is detailed under the head of Labour. When the rupture occurs if only of small extent, it may be safely left to nature, the most rigid cleanliness being observed afterwards by frequent sponging of the parts with a warm antiseptic solution as weak Condy's Fluid or Carbolic Lotion.

Where the laceration has extended through a considerable portion of the perineum the vagina may be filled with iodine gauze, and after cleansing the torn surfaces, one, two, or more deep sutures should be inserted with a large curved needle, and the margins of the wound brought into accurate position after which the vaginal plug may be removed. A finger inserted into the rectum enables the surgeon to adjust his sutures to best advantage. This operation, to be successful, should be performed immediately after the birth of the child and the bowels should not be disturbed for three or four days after which a warm water enema may be given. When the rupture has involved the rectum, one or two silver wire sutures may be passed through the margins of the

rectal rupture before the perineal sutures are inserted, the bowels should not be disturbed for six or seven days, and the vagina should be washed out two or three times a day with warm water injections, deeply stained with Condy's Fluid. Herman strongly advises the use of catgut sutures.

In ruptures of long standing, various plastic operations are recommended, the edges of the rent being pared and brought together by sutures. The modifications of this operation are very numerous, and are outside the scope of the present work.

Tait's operation is the best. It is based upon the principle of removing no tissue, so that if failure should occur the patient is not left in a worse position. It is rapid and gives excellent results. The recto-vaginal septum is split horizontally by curved, sharp-pointed scissors, and the edges of the perineal rent are also split up vertically by scissors, the edges being brought together by sutures, without transfixing the skin edges of the flaps.

Duke inserts the left index finger deeply into the rectum, and with a long, straight double-edged bistoury, he pierces the tissues in front of the anus, guiding the knife as the septum is penetrated upwards for $2\frac{1}{2}$ inches, the incision being enlarged laterally to two inches at least as the knife is withdrawn. Sutures of silver wire are inserted by a needle bearing an eye in its point.

PERIOSTITIS.

Absolute rest of the affected limb, which should be elevated upon a pillow as the patient lies in bed, and in very mild cases following trivial injury, where the inflammatory action is circumscribed, the application of Spirit Lotion under oiled silk is all that is necessary to effect resolution. Where acute periostitis follows severe injury, or appears as a complication of syphilis or of any of the exanthemata occurring in weak patients, active treatment will be necessary to relieve pain and prevent the extension of the disease. Warm water, poultices or hot fomentations applied to the affected limb, if they afford relief, should be persisted in. If they fail, leeches should be applied, and bleeding encouraged by fomenting the bites afterwards. Should these measures fail to afford relief, one or two small incisions may be made through the periosteum down to the bone. This plan effectually prevents the injurious effects of prolonged high tension, and thus minimises the after ill effects of the inflammation, and may prevent necrosis.

In severe cases it is a mistake to wait for signs of fluctuation when pain and tension are excessive. Strict aseptic precautions should be taken, and if pus is present the same treatment may be adopted, but the incision should be a bold and free one, and the knife should be felt to reach the hard bone beneath the inflamed periosteum.

After the incision the wound should be lightly packed with iodoform or cyanide gauze, antiseptic poulticing should be continued. This may be simply carried out by dressing the wound

with Carbolic Lotion (1 in 40), applied on lint, and covered with oiled silk, upon the top of which large deep pads of cotton wool may be secured by a light bandage.

Constitutional treatment will depend upon the severity of the case and the symptoms present. Where there is much fever a simple diaphoretic, preceded by a brisk saline cathartic, as that of Rochelle Salt, is a good plan. Where syphilis exists, large doses of the Iodide of Potassium are most efficacious in relieving pain and cutting short the disease, and the older surgeons employ Calomel and Opium in every case. The iodide also relieves the dull nocturnal pains in cases which are not syphilitic and there is generally no reason why it cannot have a trial in every case. The following is a good combination in the early stage. At a later stage the aconite may be omitted. —

R. Potassii Iodidi gr. lxxx.
Tinct. Aconiti mxxx.
Liquor. Ammon. Acet. ℥ii.
Syr. Aurantii ℥iiss.
Aqua Camphoræ ad ℥viij. misce.

Fiat mistura. Capiat ʒss. post cibos ter in die et hora somni.

When the temperature runs high, large doses of the iodide as a rule, are not well borne, and then a mixture containing 5 grains of Antipyrine may be given every four hours. It often relieves the pain markedly. In the later stages Iron and Quinine and strict diet are essential.

In the very severe cases where the periosteal inflammation invades the entire length of a long bone, the serious symptoms which supervene rapidly may terminate fatally in a short time unless prompt measures be taken to relieve the local and alleviate the constitutional disturbance. The first step in the treatment, as soon as the diagnosis warrants, is to make a series of deep and free incisions parallel with the shaft of the affected bone. These should pass through all the tissues and periosteum down to the bone, and may be extended into the bone (linear osteotomy) by inserting a Hey's saw into the wound.

By these means acute diffused periostitis or osteitis may be prevented from running into acute necrosis, and the shaft of the bone may be saved and the patient's life rescued. The constitutional treatment will consist in absolute rest, a highly nutritious liquid diet, and large doses of Quinine or Cinchona preparations with alcoholic stimulants. After the making of the incisions, warm antiseptic poultices should be applied every few hours, and as the progress of the case indicates the formation of new collections of pus, further incisions from time to time may be required. Where the death of the shaft occurs in spite of free and early incisions

and it becomes separated from its epiphyses, Clutton advises its removal by means of sub-periosteal resection before the formation of new bone.

Under Necrosis the subsequent management of those cases which have terminated in the formation of sequestra is detailed. For the subacute periostitis following muscular exertions, and most commonly met with in athletes, especially footballers, Dent strongly urges the use of *flying blisters*. Iodides, he says, are quite useless.

Chronic periostitis is generally syphilitic. It is to be treated upon the same general principles—rest, counter-irritants, and Mercury, with Iodide of Potassium in very large doses, and incisions when these measures fail. The writer has seen excellent results follow trephining in a chronic case which had resisted all measures. It is not unusual to come across patients suffering from chronic and painful periostitis or nodes who have been taking mercury or iodides in a desultory way for years without benefit. Such cases generally yield rapidly to large doses of the iodide (20 to 30 or 40 grs.), and full doses of Mercury just short of salivation act like a charm after a course of the iodide.

Ostitis is to be treated upon the same lines in the early stage as periostitis—rest, leeching, poultices or fomentations, blisters and counter-irritants, and large doses of Iodide of Potassium. Where these fail, and the pain continues to wear out the patient, free incisions may be made with a stout scalpel through everything down to the bone, after which linear osteotomy may be performed by cutting through the shaft with a Hey's saw until the medullary canal is reached.

Where the pain is confined to a small circumscribed area, a piece of bone may be removed by trephining.

Syphilitic cases yield generally to 30 grain doses of Iodide of Potassium, and after the relief of the more urgent symptoms of pain and tension, a mercurial course must be commenced and steadily maintained.

PERITONITIS, Acute.

It is difficult to give any concise account of the treatment of a condition so varied as that which is known under the term peritonitis. At the bed-side it is well for the student to discard the term altogether, and to only think of the disease as a *symptom* of another affection. This may not be strictly correct advice, as there may be such a thing as idiopathic peritonitis, but it is so rare that, given an ordinary case of inflammation of the peritoneum, it may with safety be regarded as secondary to inflammation of some other organ within the abdomen, to tubercle, septic poisoning, typhoid fever, perforation or rupture of a hollow viscus, hernia, impactions, intussusceptions, injuries, hæmorrhages, aneurisms, &c., or to inflammations or abscesses arising within the chest, and extending through the diaphragm. The tendency of late years is

to regard all cases of peritonitis as septic infections of the membrane whether there be intestinal obstruction or not, perforation present, as the peritonitis, say in a hernia, is caused by an invasion from the bowel of the *bacillus coli communis* which becomes most virulent in the presence of any diseased condition.

Thus it is obvious that the first step in the treatment of peritonitis is to find out the primary cause, and employ such measures and remedies as in the present state of our knowledge are best suited to the management of the primary lesion. These will be detailed under the different headings scattered through the present volume. It is lamentable to find a physician who approaching a case with the idea that he has to overcome an idiopathic affection, continues to give Opium and other anti-peritonitic remedies till a strangulated hernia is allowed to cut short a valuable life.

In the absence of such organic lesions, as must be still regarded as beyond the reach of a cutting operation (and these are few) and where the cause is obscure, an attempt should be made to modify the inflammatory action by such measures as experience has proved to be often successful.

Rest is essential. The patient instinctively learns this himself and lies in bed upon his back with the knees drawn up below the waist in mild cases, or in those treacherous varieties of peritonitis where little pain is experienced, the most absolute rest must be enforced. It may be necessary to protect the abdomen from the weight of the bed clothes by a cradle or other appliance. Great stress is laid on an advised change of posture from side to side, and protested against the dorsal position as it tended to retard the passage of flatus and favoured the formation of adhesions.

Next in importance to rest is diet. Nature also dictates this in the majority of cases by causing the stomach to reject all food and nutriment, but often the patient may be tempted to partake of food which may lead to fatal results unless clearly warned by the physician. There are few conditions demanding greater care and judgment in the selection of food. As a rule liquid nourishment alone is admissible, it should be given in very small quantities, and often. Less than a wine-glassful of iced milk may be given every two hours mixed with a little lime water or effervescing potash water, or half this amount may be given every hour.

In the case of children smaller quantities are necessary, and a thirst is sometimes prominent, this rule will require enforcement. Only the requisite amount of fluid should be handed to the patient on each occasion. A skilled nurse will not put to the lips of a thirsty and feverish patient more liquid than he is permitted to swallow at once. With young children it is a good plan to feed them with a spoon. Where milk cannot be tolerated small quantities of beet tea or beet essences may be given, and in a proportion to thirst and nausea. Ice is often abused, and strict

directions should be given for its administration. The object of the physician is to administer only as much food as is necessary, and in such a way as to prevent vomiting. Once this is started it may be no easy matter to control it. If ice be swallowed in any quantity it melts in the stomach, and accumulates till vomiting is set up. Hence only small pieces should be given, and not too often, the object being that ice or milk in small quantities may be tempted to pass through the stomach before the arrival of the next dose.

Where vomiting is a prominent symptom feeding by the stomach must be abandoned, and the rectum may then be washed out and made ready for nutrient enemata. Greig Smith advocates rectal feeding in all cases. He says—"Even if there is no vomiting the food is rarely absorbed and seems to have little nutrient value. If there is vomiting, food by the mouth is not only useless, but harmful in that it simply adds to the weary work of the patient in rejecting it." A mixture of strong beef tea and milk, thickened with a little flour or gruel, and not exceeding 4 fluid ounces, should be warmed, and just before use a dessert-spoonful of Liquor Pancreatis should be added. This may be gently thrown into the rectum every three or four hours.

At a later stage, in the absence of vomiting, other liquids may be permitted by the mouth, such as rennet chicken soup, thin arrowroot, or other farinaceous foods. It is advisable to lay down the law that in the early stages of convalescence from peritonitis only such foods, or mixtures of foods, are admissible as will pass through the meshes of a fine sieve. Sifting is unnecessary, but this statement gives the nurse and patient's friends a clear idea of what is to be avoided—*i.e.*, the administration of anything containing even fine solid particles. In the later stages the amount of liquid nourishment needs no restriction.

Alcoholic stimulants may be required where collapse is present at the beginning and in protracted cases, where debility and exhaustion are prominent features at the end of an attack. Champagne or good sparkling Hock may be useful in allaying nausea or preventing vomiting. Occasionally Whiskey by the rectum may be necessary, when everything is rejected by the stomach.

Opium comes next in importance to rest and feeding. It is indicated where there is severe pain, and, as a rule, the amount of pain present may be taken as a safe guide to the amount required. A great change has taken place in late years in the practice of giving Opium or Morphia, and gradually the rule has been formulated—to give as little Opium as possible. It never should be given as a routine. In perforative cases the slender chance of life hangs upon hypodermic injections of Morphia to combat the shock, where operative interference is entirely out of the question. The grave objection to it of masking the symptoms and mis-

leading both patient and surgeon must never be lost sight of in absolutely hopeless cases this may be ignored.

Treves states that in patients dying from peritonitis he has found more relief to follow the hypodermic injection of Strychnin. He insists upon the one indication for Morphia being pain and not restlessness or misery.

When there is no vomiting, and the pain is very severe, 10 or even 45 minims of Tincture of Opium may be given in a serious case, but it will be wiser to give two doses of 20 minims each with an interval of one, two, three, or more hours between. The effect is to be kept up by smaller doses at short intervals. The pillular form is, upon the whole the best, owing to the risk of the liquid preparations being expelled by vomiting, but it is well to begin with the liquid, and keep up the effects by pills. Where pain continues to be exacerbating, and the physician gets timorous about the absorption of the anodyne, he may give one dose by the mouth, another soon after by the rectum, and another hypodermically. In this way he need not fear accumulation. When prescribing Opium in the pillular form in such cases it is a good plan to prescribe some simple combination, in order to insure the pills being made up fresh.

Where vomiting is incessant and pain very severe, the writer prefers the modern elegant perule or pearl containing $\frac{1}{2}$ or $\frac{1}{4}$ gr of morphia. Unlike the pill of crude or powdered opium it does not appear to become insoluble, and as it is not larger than a millet seed, it can be placed upon the tongue, and is almost beyond the risk of being ejected by vomiting. The weaker strength is the best for general use, as any number may be easily administered at once. In renal disease and in very young children, Opium must be used with the greatest care.

Mercury is still a favourite in the hands of some, and is supposed to exert an important influence over the inflammatory action. This is doubted by many, and the practice of salivating for peritonitis is fortunately a relic of the past, though Calomel is often given in small doses in combination with Opium, and in the later stages of the disease it is certainly valuable; it probably acts as an intestinal antiseptic. Under its influence the tongue grows clean, and lymph and effused products rapidly become absorbed, and the bowels are probably brought sooner into a more natural condition.

Blood-letting has likewise become a practice of the past and will doubtless be entirely forgotten as the rarity of true idiopathic peritonitis is more generally recognised, but there can be no doubt about the value of leeching in many cases of purely localised peritonitis.

Leeching may be still resorted to in sthenic cases, and by its early use may relieve pain and tension, especially in cases where the inflammatory mischief is local, as in perityphlitis. A dozen leeches may be applied, and the writer has known 50 to be used in a case of general peritonitis. Where blood is to be extracted to

this extent it would seem, however, much more rational to open a large vein and make a rapid unpression upon the general circulation.

Saline purgatives have been much used in acute peritonitis of late years, and numerous cases have been reported where very satisfactory results have followed their administration in the hands of surgeons. Meigs has ably explained this by showing that in surgical practice acute peritonitis is often anticipated after abdominal operations; and large doses of Salines, administered at the very onset of the attack, may check the inflammatory action by directly depleting the abdominal and intestinal blood vessels, through the production of large watery evacuations. The physician, as a rule, does not meet with peritonitis in these very early stages.

When the disease has become established it is probable that the increased peristalsis would be a dangerous evil by interfering with the rest which is essential to the recovery of the inflamed intestinal peritoneum.

It is by quieting peristalsis and reducing the intestinal movements to a minimum that Opium becomes of value, and with our present knowledge it would seem certain that the routine administration of purgatives would in many cases inevitably lead to fatal results, especially in cases of obstruction. Nevertheless, sometimes—especially when the intestinal tube is known to be patent—salines may be of great value, but their exhibition must be always a most critical experiment. Their introduction has, however, drawn attention to the fact that the dread of purgatives has led to the opposite extreme of locking up the bowels for long periods, to the detriment of the patient. From the result of several post-mortem examinations, the writer is inclined to believe that many patients die for want of a purgative, but this number would likely be a very small percentage of those who would succumb if the administration of purgatives became a rule of common routine.

Where it is found necessary to increase peristalsis with the view of overcoming an obstruction in the bowel, a fair dose of Castor Oil is most decidedly the safest of all purgatives, but it is not the most efficacious. It may move the bowels and leave large impactions untouched, and it is, moreover, often rejected by the stomach.

Calomel in one large dose is then most efficacious, and 6 or 8 grains may be placed upon the tongue and allowed to find its way down into the stomach. Before its administration the physician must give the most serious consideration to the symptoms and general condition of the patient.

Enemata of tepid water may at the same time be steadily persevered with. They should be given slowly and deliberately, and should contain no soap or irritant, the object being to get up as much fluid as possible without exciting peristalsis, while the patient lies upon his back with the pelvis raised. The use of the

long tube, passed far up into the bowel, is, in the writer's opinion, a delusion, and much more likely to do harm than good. Messrs. who lay great stress upon the skill and judgment necessary in determining the exact moment at which a purgative should be administered in acute peritonitis, does not recommend either castor oil or salines but advises the physician to feel his way with the following combination, which may be given every four hours unless violent pain is set up:—

R. *Extract. Belladonnae* gr. ʒi.
Extract. Nucis Vomicae gr. ʒi.
Pulv. Extract. Aloes gr. ʒi.
Pulv. Rhei Rad. gr. ʒi. *misce.*

Fiat Pilula. Mille tales xii Sumat unam quartis hor.

The local treatment of peritonitis is of some importance. As a rule, pain and distension are relieved by warm poultices applied every two, three, or four hours. At first, counter-irritation by means of Mustard may be practised till the skin is well reddened after which the continuous application of Linseed Meal poultice may be proceeded with. Dr. Wales carries out this plan by means of a simple contrivance. A piece of thin flannel is laid upon a table dry mustard is rubbed into this over an area as large as the required poultice, which is then spread upon the top of it, and another piece of flannel is laid over the face of the linseed, there is thus obtained a poultice between two layers of flannel. The side containing the mustard is placed next the skin till smart counter-irritation is produced, when the poultice is simply reversed, the side corresponding to the plain linseed being then placed in contact with the skin, and allowed to remain as long as the poultice keeps warm. A large piece of spongio-piline, wrung out of hot water makes a good substitute for a poultice.

Cold applications sometimes afford more relief than poultices, and when this is the case they may be safely used during the early stages. Leister's tubes, cold compresses, bladders of ice, or wet cloths may be applied.

Various anodynes, as Laudanum, Belladonna, Aconite &c. may be tried alone or smeared over the face of the poultice. As a rule they are little worth. Turpentine is a favourite counter-irritant used in the form of hot fomentation. Strong Iodine or blisters may be indicated at a later stage, when Mercury internally may be beneficial, where it is desired to cause absorption of effused products.

When tympanitis becomes very distressing, a very fine trochar and canula or hollow needle may be used to puncture the abdomen in several regions, with the object of permitting the escape of imprisoned air. It is, however, very seldom that any marked relief follows this procedure.

When peritonitis fails to yield *very speedily* to treatment, delay of operation can only diminish the patient's chance of recovery. The one hope of saving life is by abdominal section, followed by irrigation and drainage. In recent years the tendency towards early operation has given brilliant results in surgery.

In cases of acute localised suppurative peritonitis in the female following gonorrhoea, abdominal section, with removal of the tubes and even of the ovaries, flushing the abdominal cavity out with hot distilled water, and inserting a large drainage tube, is a successful operation. It may be said that in nearly all cases of diffuse general peritonitis though the operation generally fails, the washing out of the peritoneum should be resorted to in order to give the patient a chance for life, the condition can scarcely be made worse by such a procedure. It will be found generally advisable in these cases to establish a temporary faecal fistula for the evacuation of the contents of the small intestine. The operation is liable to fail if the intestinal contents be not evacuated.

The treatment of perforative peritonitis is described later on.

PERITONITIS, Chronic.

The treatment of the chronic affection is to be carried out upon the same lines as that of the acute affection, the chief point being to find out the cause and treat it. As a general rule it may be said that the chief indication is to effect the absorption of lymph and effused fluid. Pain may require anodynes, but these should be used sparingly. Poultices, when pain is severe, may be employed, as in the acute variety, though counter-irritation is more likely to accomplish the desired end. Iodine is the best application. It may be tried in two different ways—the weak tincture may be painted on over the entire abdominal surface once or twice daily, either alone or mixed with a little weak spirit and glycerin or water, with the view of its becoming absorbed and finding its way into the lymphatics, or the strong liniment of iodine may be brushed on daily as a smart counter-irritant till the skin begins to crack. The writer has obtained excellent results from the Lin. Pot. Iod. C. Sapone gently rubbed over the abdominal surface once a day, and covered by a tightly-fitting flannel bandage.

In strumous cases, the invaluable plan for the continuous application of Cod Liver Oil under a mackintosh binder has already been fully described (see page 578). This method is of the greatest possible benefit in some cases of chronic peritonitis.

Blisters may be useful. A series of small circular or square blisters may be applied over different parts of the abdomen for short periods (two or three hours), as in the treatment of pleuritis by flying blisters. In this way fibrino-serous fluid may be got rid of without resorting to surgical measures. At a later stage massage of the abdomen may be tried.

Internal treatment may be of use, and the selection of remedies

must depend upon the primary cause of the peritonitis and upon the special or prominent symptoms present. As a rule it may be said that Cod Liver Oil, Iron, and Iodides afford the best prospect of success.

Diuretics, purgatives, diaphoretics, and hot baths, with the view of causing removal of effused fluid, are usually worthless and mercurials are seldom indicated. When they are, the best method of employing them is to smear a little diluted mercurial ointment over the cod liver oil bandage under the mackintosh and then apply moderate pressure by an outside calico binder. This pressure of itself gives considerable relief in the majority of cases.

When these measures fail to remove fluid, paracentesis may be resorted to. (See under Ascites.) Sometimes the primary affection may demand abdominal section and the removal of chronically inflamed organs or uterine appendages or the breaking down of adhesions. (See under Peritonitis Tubercular.)

Constitutional treatment in all cases is of the greatest importance. Nutritious food, pure air, change of scene, sea bathing, tonic malt extracts, and peptonised preparations, are indicated in very chronic cases.

Constipation, tympanitis, vomiting, diarrhoea, and other complications are to be met by appropriate measures.

PERITONITIS, Perforative.

The difficulty here is the decision as to whether perforation has actually occurred. Once this has been decided, there is only one rational line of treatment. Arrangements should be made to open the abdomen opened at the earliest possible moment. It can be too emphatically stated that the life of the patient depends even more on the promptness and energy of the physician who sees the case than on the skill of the operating surgeon. In the majority of cases perforation is followed by profound shock which passes off in a varying period, generally 3-6 hours, and is followed by a "period of repose." This "period of repose" affords the most favourable opportunity for operation.

In some cases the initial shock is so profound that no attempt at a rally ever occurs, the unfortunate sufferer dying within a few hours of the first symptom. In such instances there is nothing to be gained by adding to the tragedy the terrors of a surgical operation. In the more favourable cases the indications what should guide the surgeon are sufficiently obvious.

- (1) To close the perforation and prevent further extravasation.
- (2) To remove as thoroughly as possible septic and irritant substances and flakes of lymph from the peritoneal cavity.
- (3) Where the peritoneum is extensively fouled, to provide efficient drainage.

When the condition is associated with vomiting, many surgeons recommend that the stomach should be thoroughly washed at

before the anæsthetic is administered. This is no doubt a very valuable measure, as it removes the danger of vomiting during anæsthesia, and insures a period of rest and quiet after operation.

The incision is to be made wherever the operator considers it will afford readiest access to the seat of perforation. Should this not have been decided, then the middle line is selected. The perforation having been closed or a perforated appendix removed, the next step is to cleanse the peritoneum. This may be attempted by—

(1) Thorough sponging with gauze pads or sterilised sponges, and where the peritonitis is localised, which it is, in the majority of cases seen early, this is the safest and most successful plan, as it does not tend to spread the septic organisms beyond the area already infected.

(2) Prolonged douching with hot saline solution or sterilised water. All antiseptic fluids are now abandoned in peritoneal surgery.

(3) Eventration, or withdrawal through the wound of as much of the inflamed coils of bowel as can be effected, followed by thorough sponging and washing outside the abdominal cavity. The cavity itself is then thoroughly flushed out, and the cleansed coils returned. Several successful cases have been recorded, and the addition to the shock would appear to be very slight.

Finally, when fouling has been general or sepsis virulent, free drainage must be provided for. This is now generally carried out by the use of strips of sterilized gauze, but rubber drainage tubes are still employed by many; the well-known glass drainage tube is now rarely used.

Where the intestine is greatly distended it will be opened and emptied, and before closing the wound and returning the bowel it is good practice to inject into its lumen a strong solution of Magnesium Sulphate, which stimulates subsequent secretion.

After operation a single hypodermic injection of Morphia, $\frac{1}{4}$ –1 gr., may be given with advantage; it relieves restlessness and diminishes pain, and in this way insures a short repose and secures deep respiration, the diaphragm moving more freely owing to absence of pain. The movement of the diaphragm stimulates the flow of lymph, and this encourages peritoneal absorption.

The results of this active treatment are distinctly encouraging, and are each year becoming more so. Thus Pearce Gould has recently reported twelve cases of acute general perforative peritonitis all operated on with seven successes.

Even in perforation occurring in typhoid during the acute stage, several successful operations have recently been recorded, whilst recovery has been the rule after laparotomy for perforation during convalescence.

The most brilliant results have, however, been obtained in perforating gastric ulcer. The shock following such operations is

a common cause of death, and must be vigorously combated. Saline injections into the subcutaneous tissues or into a vein, where there is reason to hope for absorption, into the rectum, hypodermic injection of Strychnine, Whiskey by the rectum, external warmth, and elevation of the lower limbs, may all be called for—before, during, or after operation. (See also page 316.)

PERITONITIS, Tubercular.

The treatment of *acute* tubercular affection of the peritoneum will consist in the exhibition of those remedies which give relief in acute tuberculosis, as large doses of Quinine or Antipyrene to reduce the high fever generally present together with the measures which experience has proved useful in the treatment of acute peritonitis, as rest, poultices or warm fomentations, Opium, liquid diet, ice &c. The question of abdominal section in such cases need hardly be discussed because the diagnosis is uncertain in the early stages, and as the disease may be general, operative measures would be contra-indicated and lastly, acute tubercular peritonitis is not often associated with purulent secretion in the abdominal cavity. Suppose however, a case of acute tubercular peritonitis, could such a case be diagnosed with anything like certainty abdominal section and free washing out of the peritoneal cavity, with the establishing of free drainage, would be justified.

The treatment of *chronic* tubercular peritonitis formerly regarded as incurable affords one of the most striking and brilliant examples of the success of modern abdominal surgery.

For the relief of symptoms by general medical treatment little need be said beyond reminding the reader that the management of a case of this disease will consist in the judicious exhibition of those remedial agents indicated in the treatment of chronic tuberculosis along with the administration of remedies suitable for the relief of the accompanying peritonitis. The relief of pain, constipation, diarrhoea, hectic fever, and the prevention of debility and emaciation until the patient can be placed in a position in which there is some hope of his throwing off the tubercular disease by change to a more suitable climate constituted the routine treatment till lately universally adopted. The great value of the Cod Liver Oil emulsion, and its continuous application by means of the binder and mackintosh, have already been referred to.

Biagi has reported 6 cures from hypodermic injections of Iodine ($\frac{1}{4}$ grain), dissolved in an Iodide solution. Iodine externally in the form of emulsion, ointment, or oil, or Sclavo's iodized milk is a more rational method. Yeo recently has advocated the use of Iodoform rubbed into the abdominal wall in conjunction with the internal administration of the drug along with Creosote.

Abdominal section has been performed in many hundreds of cases with a success which could hardly have been anticipated.

The abdomen has been incised, washed out thoroughly with warm water or weak antiseptic liquid, and drainage established where this was necessary. Ascites as a rule never occurs again, and hence future tapping is unnecessary. Tait reported a complete cure of the disease in 80 per cent. of all cases of tubercular peritonitis in which the abdomen was opened, cleansed, and drained.

The statements of König are hardly less surprising. He collected 131 cases of peritoneal tuberculosis treated by abdominal section, of which 23 were greatly improved, 84 were cured (65 per cent.); of these, 30 exhibited no signs of intra-peritoneal tuberculosis for several years following abdominal section. In only 3 per cent. could death be attributed to the operation. Aldebert gives complete recoveries in $\frac{1}{4}$ of all cases operated upon, and "cures" he puts down as 70 per cent., or 215 out of 308 cases, mortality from operating being only 2.5 per cent. Tillmann's recent list of 358 cases also gives very satisfactory results.

The operation is thus firmly established and, doubtless will be widely recognised in the future as a routine, although abdominal tubercle has been proved of late years to possess a spontaneous tendency to recover. The most suitable cases for operation, and those in which the largest percentage of recoveries are to be expected, are those in which there is much effusion of fluid. But in many instances of the fibrous or dry form, in which exploratory incision revealed matting together of the coils of intestines and adhesions beyond remedy, good results unexpectedly followed. Much relief and improvement generally follow in those cases, which ultimately yield to the progress of the tubercle which at the same time was present in the lungs and other parts of the body.

Much difference of opinion exists still about the explanation of the results: a study of the reports shows that success often attended operations where no antiseptics were employed, and where even washing out of the abdominal cavity by sterilised water was omitted, and where no ascitic fluid was removed, because none existed, and where even no appreciable amount of daylight could have been admitted through the small incision, and where little manipulation of the parts apparently was resorted to or drainage established. These considerations have led some surgeons to try tapping and the injection of a stream of sterilised air, or some antiseptic liquid, but these methods have not found many supporters.

Upon a survey of the literature of the operative treatment there really appears to be only one procedure common in all cases, viz., an abdominal incision of varying length and it is almost impossible to attribute to this universal factor all the benefits and successes which have followed the operations.

Before the operative treatment of tubercular peritonitis was thought of or known to the writer he had been much impressed

by a few unexpected successes following some excisions of large joints, like the knee or elbow, which he had witnessed in the practice of surgeons, and he had asked himself the question—Was it possible that the prolonged inhalation of Chloroform was a factor in the recovery of some cases where evidently all the tubercular disease was not removable? He believes that this is a possible (and more than a possible) explanation of the results of operative interference in tubercular peritonitis, whilst it may not be a factor of much or any importance in the surgical procedure for other forms of tubercle, because it is a certain clinical fact that tubercle of the abdomen is more amenable to treatment and more liable to spontaneous recovery, as it possesses less power of resistance than tubercle in the lung, bones, or glands. In addition to the universal incision, the constantly present element of the anæsthetic has been overlooked in analysing the factors of success. Familiarity in the hourly use of chloroform and ether breeds contempt as regards their being a possible factor in the surgeon's success, as a means of producing the necessary anæsthesia for his manipulations. The blood charged with the vapour of chloroform during a prolonged abdominal operation may possess a bactericidal power of sufficient degree to overcome the resistance of tubercular growth under conditions already very unfavourable to it. Moreover, it has been long known that chloroform inhalation leads to changes in the white blood cells, and the possibility of an antitoxin or of an increased phagocytosis being produced is not altogether fanciful. Dr. A. B. Mitchell, at the request of the writer, tried the administration of Chloroform alone in two cases of abdominal tubercle without success, but it must be said that they were both of the most advanced and hopeless type and such as it could hardly be possible to hope would have benefited even from an abdominal incision. The writer will await with interest the reports of cases treated by this method by any surgeon to whom these suggestions may appeal. The success of a few operations performed under cocaine or any other local anæsthetic will not be sufficient to negative the above hypothesis of the value of prolonged chloroform narcosis in tubercular peritonitis.

PERITYPHLITIS.

This term has come to be practically synonymous with appendicitis. Typhlitis or inflammation of the caecum itself is so rare that its treatment need not be considered. The first steps in the management of the localised peritonitis, which constitutes the main element in perityphlitis or so-called appendicitis, are those which have been already mentioned under peritonitis. The patient must be at once confined to bed and placed upon his back and absolute rest insisted upon. A hot tomentation should be applied to the abdomen or as many prefer, cold applications as the ice-bag or coil, may be substituted, at a later stage leeching often gives great relief.

Small quantities of milk or other liquid nourishment should be given hot but when vomiting or nausea becomes marked the patient must be fed by the bowel. Formerly the recognised routine was to put the patient under morphia or opium, and insure relief of pain and rest to the bowel; then came in late years the dictum that all narcotics are dangerous and must be avoided, and that best results obtainable were to be got from purgatives and surgery. Recently the indications for and against opium are being more clearly recognised and understood, and a more rational method of dealing with the disease is adopted, though there are still serious differences of opinion upon many cardinal points.

As regards narcotics, it is clear that the pain should be at once relieved by a moderate hypodermic of Morphia ($\frac{1}{4}$ to $\frac{1}{2}$ gr.), and that if the drug be skilfully administered pain may be relieved from time to time without the "masking" of the symptoms, which is dreaded from its tendency to lure the physician and patient into the delusion that all is going well when the opposite is the case. McBurney states quite recently that "Cathartics should not be employed, as they increase peristalsis and nausea, and, so far as is known, have no beneficial effect upon the disease," whilst Treves maintains that a purgative should be given at once in every mild case, as he constantly has seen the affection cut short by an enema or by 1 gr. Calomel or 2 drs. Sulphate of Soda every hour for four or five doses. The rule which the writer adopts is always to administer an enema as soon as the case comes under observation and if the temperature is high, to give moderate doses of Salicylate of Sodium every six or eight hours.

Many, indeed the great majority of all cases (excluding those of grave severity from the outset), recover under this treatment, but many surgeons still consider such a routine as very reprehensible, and urge operative interference in nearly every case. Thus McBurney, writing in 1900, states that "No medical treatment of proved value has ever been presented, and that every case of appendicitis is liable sooner or later to demand surgical interference for its cure." He insists that every patient who has had a single clearly-defined attack should have his appendix removed in the quiescent period before a second attack can occur.

In this country very early and universal operative interference has few advocates. As a rule, the operation is delayed till the symptoms indicative of pus formation are established. In those grave cases where symptoms and signs of perforation show themselves at the commencement of the attack all authorities agree that the opening of the abdominal cavity should not be postponed for a moment. Every case from the time that it comes under observation should be closely watched, for sometimes the mildest example may suddenly become severe, and a case where operative interference is not indicated may in 12 hours or less, present symptoms of such gravity as demand laparotomy or free incision.

Relapsing appendicitis constitutes a considerable proportion of the cases of perityphlitis which present themselves for treatment. Here the advances in abdominal surgery made during late years enable the surgeon to lay down a clear law to which there should be practically no exceptions. Where a patient has suffered from several severe attacks of appendicitis, increasing in intensity and obviously placing his life in danger, the appendix should be removed during a quiescent period. Treves has performed this operation 150 times with only 1 death.

PERSPIRATION, Excessive.

Under Phthisis, the various remedies for the profuse perspiration which accompanies the septic stages of that disease will be discussed. In the great majority of other cases where excessive perspiration is present it will be found to be secondary to some primary affection which requires treatment, as chronic alcoholism, influenza, obesity, Graves disease, acute rheumatism, ague, &c.

In those comparatively rare cases where hyper-secretion of the sweat glands occurs, independent of any other affection, some abnormal condition of the vaso-motor nerve supply is probably present and may require treatment. The clothing should be light and absorbent, thin flannels being the best fabric for wear next the skin.

The skin should be bathed in very hot water to which vinegar is added in cases where there is no elevation of cutaneous temperature, cold douching alone or following hot sponging often is useful, and smart friction is afterwards to be employed. Unna then advises an ointment containing Ichthyol and Turpentine to be rubbed in before bed-time. This is to be washed off in the morning, very cold water is to be used and thorough friction, after which a powder containing mustard is to be dusted over the skin. In cases where the skin is warm he advises the use of the Ichthyol Ointment or Soap. Of the various powders the best is Starch, mixed with Tannoform, Boracic Acid, and Salicylic Acid in the proportions of about 12, 4, 4, and 1.

Some authorities recommend theunction of the entire body with Sweet or Neat's Foot Oil. Of internal methods of treatment, the writer believes that a very dry diet with the least amount of fluids gives the best results.

Atropine $\frac{1}{16}$ to $\frac{1}{8}$ grain, three times a day, alone, or with 15 to 30 minims of the Liquid Extract of Ergot, may be tried. Sulphuric Acid, Tannin Quinine Strychnine, Agaric, minute doses of Pilocarpine, Sulphate or Oxide of Zinc and nearly every remedy found useful in diminishing the night sweating of phthisis have been used but their effects are very transient. Crocker gives a tea spoonful of Milk of Sulphur twice a day in a little milk.

A three-grain tabloid of Sulphonal, twice or three times a day, is a very good remedy where the perspiration is general.

Arsenic and Iron in combination with Nux Vomica may be tried and the continuous current is sometimes useful.

It is, however, generally in cases of local hyperidrosis, accompanied by an unpleasant odour in the perspiration that the physician is consulted. This affects most commonly the feet and toes or the arm-pits and groins. In feet cases the affection is sometimes so severe as to make the victim a nuisance to others and relief is most desirable. The internal remedial agents may be tried but the writer seldom employs them at all, as local treatment will give excellent results in the great majority of cases when the patient can be got to carry it out thoroughly. (See under Bromidrosis, pages 92 and 93.)

PERTUSSIS.

Isolation is the first question to be settled. This is to be decided upon the peculiar nature of the patient's surroundings, and as generally will be required for 8 or 10 weeks under ordinary circumstances there is no use in beginning a system of isolation in a half-hearted way, nor is there any use in insisting upon it where it is almost certain to break down in a few weeks. Moreover, a plan of isolation should be accepted which will confine the patient to one room during the entire illness. As a rule, in this country the patient's parents, who generally know a good deal beforehand about such a common disease, refuse to carry out a system of real isolation. The writer's practice is to warn the patient's relatives of the danger which might arise if some weakly member of the family were to catch the contagion and to urge upon them the advisability of placing two rooms in the house at the disposal of the invalid and advise that the others should be sent away.

The child should have one large well-ventilated sleeping and one play-room, especially in the winter time, and at all times when possible. This is a matter of more importance than nurses and parents can be made to see. As will be mentioned later, disinfection being necessary during as well as at the termination of the illness everything capable of being injured by the fumes of burning sulphur should be removed. The air of the room can be medicated by the methods to be mentioned later on, the temperature of the chamber is an important matter. In severe cases requiring to be kept indoors, the temperature of the room should be kept at 65° F., but it is a serious mistake to do this and permit the child to go out into the cold air. The second room in these cases can be used as an "intermediate."

The next point to be settled is the one of permitting the child to go out-doors. Moderately strong children, even in smart attacks, not only are safe, but are much better for being out all through the attack. Plenty of fresh air is really of more importance than medicine in a long illness like whooping-cough. Of course, in severe weather, with rain and cold, or during the prevalence of

the spring east winds, or in the presence of any bronchial complications, out-door exercise must be forbidden.

Diet is of great importance, and, in the management of weakly young children, will turn the scale for or against recovery. The usual diet which experience has proved to agree best with the child is to be continued, provided it be wholesome and highly nutritious. A mixed and varied diet does best with grown-up children. After the paroxysms have become thoroughly established and the appetite begins to fail, the patient must be coaxed to take milk or other nutritious fluid nourishment between meal times.

After a time, when the paroxysms are attended by vomiting, the critical period in the dieting arrives. The nurse should be directed to withhold food for a short time in the presence of a threatening or expected attack of coughing, and to aim at having the child fed as soon as possible after an attack, so as to permit the food to be as long as possible in the stomach before the next turn of vomiting. By carefully attending to this hint lives may be saved.

Hard, indigestible food in the stomach, as nuts, green fruits, unripe apples, &c., will increase the laryngeal spasm, and portions of unchewed beef and potatoes may give serious trouble during the act of vomiting. Hence, upon the whole, a liquid diet is to be preferred for small children, or the ingredients should be carefully comminuted.

Clothing should be warm, and so arranged as to prevent overheating at one time and chills at another, an even temperature and the avoidance of draughts being desirable. Light flannel under-clothing is essential, except in very warm summer weather.

During the paroxysms young children should be lifted on to the nurse's knee or lap and every constriction about the neck or chest should be removed. Naegeli states that the paroxysms may be arrested by simply pulling the lower jaw downwards and forwards, and this is effective also during sleep.

As regards drugs, the list is a long and tedious one to discuss. Most physicians find themselves after a time settling down to the routine employment of one or two simple expectorant agents. Active or heroic medication is to be condemned. Since the improvements in our knowledge of bacilli and the part played by them in the various infectious diseases, many germicides have been tried in the treatment of whooping-cough, but to none of these can a specific action be fairly attributed. The plan of treating the disease by inhalations can hardly be said to have proved a success, though antiseptics of a volatile and unirritating nature certainly appear to modify and sometimes to shorten the duration of the disease.

Carbolic Acid in the form of a spray (1 in 100) may be inhaled by the patient three or four times a day, or a stronger spray may be diffused frequently through the air of the room. The plan of forcing young children to submit to such solutions being sprayed directly into the mouth is not to be recommended. They often

increase the frequency and severity of the paroxysms. You must upon the great value of carbolic acid inhalations. In the sick room he keeps by the fire a large iron dripping spoon for vaporising carbolic acid, which should be used till the air of the room becomes unpleasantly strong with the fumes. At the same time he uses a spray of 1 dr. glycerin of carbolic acid, 10 grs. bicarbonate of soda in 1 oz. hot water, to be sprayed in front of the patient's mouth and nose. In addition he causes a warm 5 per cent. spray of carbolic acid to be diffused through the air, and sometimes a young infant's brushes the pharynx and larynx with glycerin of carbolic acid.

No objection can be made to the air of the sick room being impregnated with a volatile antiseptic like Turpentine poured over the surface of hot water. Terebene, Eucalyptus Oil, Peroxide of Hydrogen, &c., may be similarly used, and they are of the greatest benefit where several children are confined in one room in severe weather.

Creosote is praised by Godson, who gives it by the method of continuous inhalation, the drug being sprinkled upon cloths hung up in the sick room, and he states that it produces an immediate effect upon the paroxysms, which are rendered less frequent.

The nascent Ammonium Chloride inhalation mentioned upon page 94 is also most valuable, especially where there is much bronchial catarrh.

Oil of Eucalyptus has been praised as an inhalation and as a spray, and even when given internally. Hardwicke mixes it with turpentine and spirit as a spray, whilst he gives the turpentine internally at the same time.

The following spray may be diffused through the room several times a day :—

R. *Olei Eucalypti* ℥ii.
 Olei Terebinthinæ ℥i.
 Thymol ℥i.
 Spiritus Lavandulæ ad ℥vi. misce

Little can be said for the methods suggested for cutting short the disease by the application of various solutions to the fauces, larynx, and the strong solutions of Cocaine recommended are dangerous, as well as useless in most cases.

Resorcin Spray, 2 per cent., is safer, and very glowing reports of its use are published. Dawson Williams states that from the local application of a 2 per cent. resorcin solution to the throat he has seen more striking results than from any other method of treatment. Richardson extolled the Peroxide of Hydrogen as an inhalation and internally. Strong solutions of Caustic or Nitrate of Silver are still painted over the fauces by some. Raubitsch has reported successful cases by swabbing out the fauces and

palate with 1 per cent. solution of Corrosive Sublimate, and allowing a little to trickle down over the epiglottis.

Carmichael and Payne maintain that the disease is best cut short or cured by free and copious irrigation of the nares by solution of Carbolic Acid (1 in 40).

Solutions of Quinine, Salicylic Acid, Nitrate of Silver, Corrosive Sublimate (1 in 10,000) have been injected into the nose, and Benzoic Acid or Benzoin, Quinine, Iodoform, Boracic Acid, Tannin, Bicarbonate of Soda, Alum, and Pulverized Marble, have been used as insufflations.

Bartholow used for insufflation a powder consisting of 1½ drachms of Salicylate of Bismuth and Powdered Benzoin and 18 grains of Quinine.

An ointment of 1 part of Eucalyptol, 1 part of Iodoform, and 16 parts of Vaseline, is a well-known nasal application.

Upon the whole, the reports of these methods from impartial observers are not satisfactory, and the writer cannot speak from personal experience.

As regards internal remedies, the difficulty perhaps would be in finding any considerable number of well known drugs which have not at some time or other been pressed into the service as specifics for whooping-cough. Only a comparatively small number of the so-called specifics can be mentioned.

Given an ordinary case of pertussis in the early or catarrhal stage, the diagnosis, of course, will be at first somewhat doubtful, unless other children are suffering from the affection in the same house. The writer's plan is to order a simple expectorant like the following and await events. For a child 7 years old the following may be prescribed:—

R. *Vin Ipecacuanha* ℥v
Tinct. Scilla ℥ii.
Tinct. Camphoræ Co. ℥iv.
Syrupi Tolutani ℥iiss
Aquæ Chloroformi ad ℥iv. misce.

Sumat cochlearium minimum quater in die ex paululo aquæ.

In mild cases of the disease this mixture may be continued all through, but, as a rule, when the crowing begins it will be beneficial to substitute 3 or 4 drachms of the Bromide of Ammonium for the tincture of squill. Upon the whole there is no safer treatment than that by the bromides, and they may be given all through the disease. If a little Antipyrine be added the best all-round routine treatment will be obtainable.

Such simple treatment will do something to ward off chest complications, as the administration of ipecacuanha appears to exert some influence in preventing further catarrhal trouble if the

patient is permitted to run about in the open air. The medicine should be given soon after meals. The Oxy-mel of Squill may be often employed instead of the above mixture with advantage.

When the paroxysms become severe and frequent, say up to a dozen or more in a day and when their intensity begins to tell upon the patient's strength, several drugs have a claim upon the physician's attention after bromides fail. These are Chloral, Antipyrine, Belladonna, Morphia, Conium, Quinine. The writer names them in the order in which they will, in his opinion, be likely to give most satisfactory results.

Chloral certainly possesses marked power over the spasmodic element in the disease. The usual rule for dosage is one grain for each year of the child's age, but it is better to give half this amount, and more frequently, say every two hours, and even then a still smaller dose may do. It should, however, be always remembered that chloral is a dangerous drug in the presence of cardiac weakness and in complicated cases it must be used with caution. Chloralamide and Chloralose have been also vaunted.

Morphia also is anything but a harmless drug to administer to very young children especially when there is profuse bronchial secretion. The physician can, however discreetly feel his way with it. Henoeh, whose experience is great, prefers it very much to all other narcotics, and he says, speaking of the remedies used in allaying the spasms of whooping-cough:—"I have now come to put trust only in one, namely, Morphia, which is far more efficacious than the much-used belladonna—at any rate in relieving the violent attacks, especially those occurring during the night, and in diminishing their frequency." It may be used alone, in conjunction with the expectorant combination mentioned upon the previous page, or along with belladonna, antipyrine, or chloral. With this latter drug it goes well, and when both are given together less of each is required, and greater safety obtained.

Henoeh's formula is the following:—

R. *Morph Acet. vel Hydrochlor.* gr. $\frac{1}{2}$ to gr. $\frac{1}{4}$
Syrupi Simplicis ℞ss.
Aquam ad ℥ss *misce.*

Signa—"A tea-spoonful twice to four times daily"

He does not state for what age this is suitable, but it may be given in the weaker strength to a child two or three years old. When drowsiness supervenes, the nurse should be directed to suspend the medicine.

Belladonna or Atropine is a favourite remedy with many for the spasmodic seizures, but it must not be forgotten that, to be of

any practical use for this purpose, it must be given in doses bordering upon dangerous. The physiological effect of the drug must be obtained, and since all the belladonna preparations are now standardised, it matters little which be selected. A child three years old may receive $\frac{1}{2}$ minim of the official solution of Atropine (i.e., $\frac{1}{10}$ grain) every four hours till the pupil dilates, or 10 minims of the tincture of belladonna may be given instead; an infant one year old may get $\frac{1}{2}$ to $\frac{1}{4}$ of these doses. The extract is only to be used when the pilular form is selected. This is unsuitable for children.

When the physiological action of the drug has been obtained, smaller doses are then necessary to keep up the effect. Children bear the drug very well, much better than adults. The above doses may be given every few hours for many times without producing any effect beyond relief to the paroxysmal attacks. Sometimes the remedy fails completely, and where serious complications exist it should not be administered. The first evidence of delirium should warn the patient's friends or nurse to stop the medicine. Though this practice has had the sanction of the very highest authority, the writer has ceased to use it because of its danger and the amount of anxiety which attends the treatment of a case of whooping-cough by a remedy so powerful. It appears to act best and to require smaller doses when the disease reaches the end of the third week. This remedy may be safely combined with chloral or with morphia advantageously. Thus for a child one year old, the following may be given:—

R. *Liquor. Atropinæ Sulph.* min. x.
 Chloral Hydrat. 3ss.
 Liq. Morphinæ min. xii.
 Syrupi et Aquæ ad 3iii. *misce.*

Fiat mist. Cpl. 3i. quater in die.

Antipyrine has been tried with varying successes, and the reports are contradictory, chiefly because the first statements were so roseate, and subsequent observers tried the drug, expecting results which were not fulfilled. Nevertheless, it is clear that this agent possesses some influence over the severity of the paroxysms and the duration of the disease. It is best given alone, and a child one year old may get one grain every four hours. The writer has given twice this amount to a child under one year. It may be given in solution in water well sweetened with Syrup of Tolu.

The usual diaphoretics or diuretics, as spirit of nitrous ether, sal volatile, &c., should not be ordered in combination with antipyrine. It acts best when given in the early stages of the disease. Sonnenberger recommends three or four doses in the

twenty-four hours, consisting of as many decigrammes ($1\frac{1}{2}$ grains as the child counts years, or as many centigrammes $\frac{1}{2}$ grain as the child counts months. With these doses the cough is diminished, the paroxysms become less frequent, and the duration of the affection is lessened. Antifebrin and Phenacetin have been used in the same way, but, upon the whole, their action appears to be less uniform and satisfactory, and they do not possess any advantages over antipyrine. The following is a very good formula for a child two years old :—

R. *Phenazoni* *ʒi.*
 Ammonii Bromidi *ʒi.*
 Sodii Bromidi *ʒi.*
 Syrupi Chloral *ʒvi.*
 Aquæ Chloroformi ad *ʒiv. misc*
Fiat mist. cpl. coch. min. tertius horis.

Conium has been often employed, and appears to modify the severity of the paroxysms when other measures have failed but it is the least reliable of the remedies already mentioned, and is useless in all cases unless, like belladonna, it be given in doses capable of producing its physiological effects. The fresh juice is the only reliable preparation, and of this large doses may be safely given. Ringer gave nearly one ounce every hour to a choreic child. For a child 3 years old, 30 minims may be given, and repeated every one or two hours till the physiological effects of the drug are beginning to show themselves. Upon the whole the uncertainty of its action and the anxiety to the physician of giving a drug in such doses as cause ptosis and difficulty in swallowing are not qualities to recommend it, unless every other remedy has failed.

Quinine is vaunted by many as almost a specific in whooping-cough. Its bitter taste is an almost insurmountable barrier to its internal administration to children, and the writer has ceased to employ it on this account, except in cases where there is a high temperature, and where the previously-mentioned remedies have failed. It has, moreover, another objection, which appears not to have been noticed by those who recommend it—it tends to dry up the secretion of the bronchial tubes, and in this way it increases the difficulties of expectoration, and hence it should be very cautiously given where there is much bronchial catarrh. The sulphate, murate, or tannate may be given per rectum in two full daily doses. A child three years old may get 4 or 5 grains in this way in the 24 hours if the paroxysms are very frequent and severe. These doses appear to diminish reflex excitability. Baron gives $1\frac{1}{2}$ grains for each year of the child's

life three times daily. It is most useful in the later stages of the affection.

Roth uses a solution of Iodized Phenol for internal administration. The following is a modification of his formula —

Acid. Carbolic Purif., gr. xv. Spiritus Chloroformi m. xv.
Tincturæ Belladonnæ, m. xxx. Tincturæ Iodi, m. x. Syrupi et
Aque ad ℥i misce. Fiat mistura.

Of this he gives a tea-spoonful every two hours to children between two and twelve years. Of carbolic acid the dose seems a large one, and of belladonna the amount is too small to be of any use whatever. There is no doubt that small doses of carbolic acid are useful. One minim of the glycerin may be given every three hours to a child two or three years old.

Rachel recommends the administration of 5 minims every two hours of a two per cent. Solution of Chloride of Gold and Sodium.

Richardson advocated the administration of Peroxide of Hydrogen in the form of Ozonic Ether as almost a specific for whooping-cough.

Bromoform has had the sanction of many of the highest authorities. One minim for a child 1 year old may be given every three hours in mucilage and syrup. Three times this dosage is recommended by several, and glowing accounts of its virtues are numerous. The writer has never prescribed it in this affection. Dr. W. T. Mills mixes a little senega with the bromoform, which produces a perfect emulsion and minimises the risk of inequality in the doses.

Eustace Smith, in the later stages, if the spasm still persists, gives Liquid Extract of Grindelia, 10 mins. every 4 hours to an infant.

Yeo's favourite mixture consists of Benzoate of Soda, 72 grs.; Bicarbonate of Soda, 48 grs.; Chloride of Ammonium, 24 grs.; Chloroform Water, 1 oz., Anise Water to 3 oz., of which 1 to 4 drs., according to age, is given every 4 hours.

Cocaine in small doses has sometimes appeared to give good results, but it is not to be recommended save as a remedy to control obstinate vomiting.

Alum, in doses of 2 grs. for a child 3 years old, may be given every 3 or 4 hours, and is a favourite remedy with some.

Chloride of Ammonium may be given in the same way, or in combination with alum or the bromides.

The Oxide of Zinc is an old-fashioned remedy, and the writer has seen it do well in mild cases. A child 2 years old may get 1 grain.

Sulphate of Zinc is also used in the same way in doses bordering upon nauseating.

Ouabain, a crystalline glucoside obtained from an arrow poison, has been used by Gemmell in whooping-cough in all stages, and he reports most favourably of its value in cutting short the attack

if given early, or of diminishing the number of whoops if given in the later stages. It may be administered in water, the dose for a child under 12 months being $\frac{1}{10}$ grain every three hours. Double this dose, i.e., $\frac{1}{5}$ grain, may be given to a child three years old. (There is much confusion, however, about the quantity of glucosides, see Author's "Materia Medica," 7th Edition, page 573.)

Chloroform and Ether may be occasionally employed as inhalations to the extent of producing mild anaesthesia where the severity and frequency of the paroxysms appear liable to end fatally by preventing sleep or feeding. They will be very rarely necessary and can, of course, only be used at long intervals, and then only for a few minutes.

Chloroform has been used by adding a few drops (2 for every year of the child's age) to warm water in any ordinary inhaler, and breathing the vapour four times a day.

Nitrite of Amyl is sometimes of use in such cases, and Hyoscin has even been recommended.

Andeer publishes surprising results from the administration of small quantities of Resorcin.

Cannabis Indica has been used where opium or chloral cannot be given, and where a narcotic is indicated.

Ergot is still vaunted as a specific, but it possesses no action over the disease.

Senega, Lobelia, Checken, Grindelia, Clover, Tartar Emetic, Terebene, Turpentine, and other expectorants, are still supposed to act beneficially and sometimes specifically upon the paroxysms.

Hydrocyanic Acid is occasionally very useful in relieving cough and spasm.

Gelsemin, though a dangerous drug for very young children, is sometimes recommended where the spasmodic element is unusually well marked.

Valerian, Asafoetida, Camphor, Ergot, Musk, and Sumbul are also recommended in these cases, and there are still those who believe in the internal administration of the Dilute Nitric Acid.

A blister to the nape of the neck sometimes seems to lessen the amount of spasm, and leeches applied to the same region, or to the larynx, have been recommended, as have also been Lister's tubes and iced compresses. The removal of adenoids when present in protracted cases generally does great good.

In the later stages of the disease there is nothing so valuable as a change of air, and the old plan of bringing children to the gas-works, and allowing them to breathe the fumes of gas-burners has been often found to lead to rapid improvement. Various plans have been devised to carry out some treatment upon the same principle at home, without exposing the children to the vicissitudes of weather. The various inhalations already mentioned have been employed with this intention, and the odour of Coal Gas, of Sulphuretted Hydrogen or Sulphurated Potash Solutions have been recommended. Of all such measures, however, the plan of

Sulphurous Acid fumigation as carried out by Mohn, is by far the best. The writer has seen excellent results from it in the later stages of the disease, and he believes it should always be employed occasionally during the middle and several times towards the end of the treatment of every case of whooping-cough.

The plan consists in removing the patient from his sleeping room in the morning, after which Sulphur is freely burned in the room $6\frac{1}{2}$ drachms per cubic metre of air space, with the door and windows closely shut for at least five hours. After opening all outlets and inlets, and ventilating the room till the air can be safely breathed, the patient, with clean linen garments, is to be brought back in the evening and put to bed, and Mohn maintains that he awakes cured next morning. Certainly, sometimes the paroxysms appear to rapidly diminish after this procedure. Some authorities burn small quantities of sulphur constantly in the sick chamber all through the attack, but this must be done with great caution.

Of the recently suggested methods of treatment as vaccination, antidiphtheritic serum, CO, by the rectum, Oxygen inhalations, O'Dwyer's tubes, Formalin applications, &c., &c., little need be said, as most of them must share the fate of the many hundreds of so-called specifics which are allowed to die yearly.

In the convalescent stage remedies which improve nutrition may be given. Cod Liver Oil and Syrup of Iodide of Iron are the best of these. Arsenic in small doses is of use when convalescence is protracted, and counter-irritation by means of stimulating liniments to the chest is useful in all stages of the affection. A favourite external application is the Oil of Amber, which is also given internally; but the most valuable liniment is, in the writer's opinion, the Oil of Eucalyptus, which may be applied alone or with an equal quantity of Olive Oil or Spirit of Camphor. By this means, if freely used the patient often breathes for a short time in the day and at bed-time a purified atmosphere.

The following application may be used.—*Olei Eucalypti*, ʒij , *Linimenti Camphoræ*, ʒij , *Olei Cajuputi*, ʒiv ; *Olei Menthae Pip.* ʒij . *misce*.

PETIT MAL—See under Epilepsy.

PHAGEDÆNA—See under Gangrene (Hospital).

PHARYNGITIS, Acute.

The treatment in severe cases will consist in a smart Saline purge, and the administration of any simple diaphoretic mixture.

To the throat may be applied a weak solution of Carbolic Acid, with or without Cocaine, either in the form of gargle or spray,

R. *Acidi Carbolici* ʒj .
 Cocaina Hydrochlor. *gr. viii.*
 Glycerini Boracis ʒss .
 Aquæ Rosæ ad ʒxii . *misce*.

rest of the affected parts that can be possibly obtained should be insisted upon till the treatment is well started.

A long sea voyage often succeeds after the failure of every known drug, singing, loud speaking, smoking, and over-indulgence in alcoholic stimulants, and rich high-seasoned dishes must be forbidden. In ordinary cases sea bathing is of service and a cycle ride of several miles along the coast afterwards if the weather permits, is of great benefit.

Whilst every known means of improving the general health is to be persisted in, the internal administration of drugs is of little moment except in so far as it assists general building up of constitutional vigour. Iron may be given alone or in combination with Quinine, Arsenic Phosphorus, Iodine, or Cod Liver Oil. This drug is essential in many cases, as the disease is so frequently associated with anæmia.

Free purgation by means of any of the natural mineral waters, or a sojourn at Carlsbad, Aix, Kissingen, Ems, or Harrogate may be beneficial.

Local treatment is always of the greatest importance. This is to be carried out upon the same lines as in treating chronic pharyngitis, soothing Carbolie Lotions or sprays being employed where there is much local pain or irritation. Any of the astringent gargles, sprays, or swabs may be tried, but as a rule, little may be expected from these measures in very chronic cases associated with much hypertrophy or numerous granulations. These must be destroyed if a radical and permanent improvement is to be aimed at.

By far the best method of treatment is to apply the galvanocautery to each granule, and at the same time cause obliteration of any large veins in the diseased membrane.

Nitrate of Silver fused upon the end of a strong silver probe may be employed to destroy the granulations, only a few being operated upon at each sitting. A strong solution of the nitrate (1 drachm to 1 oz of distilled water) is a favourite means of carrying out this object; but it is a mistake to paint over any considerable area of the pharynx with this at one sitting, owing to the irritation which may ensue, unless much ulceration is present. Every second or third day is often enough, and the Carbolie Lozenge or spray may be frequently used before and after each application. Cocaine may be employed to lessen the pain and irritation. Lawrence sometimes uses "London Paste" for the destruction of the granules, but Butlin scrapes them with a Meyer's ring knife.

Rault's method of "Grattage" is reported as being very successful. The pharynx is painted with cocaine, a hard brush with the hairs cut short is dipped into a 10 per cent Solution of Iodine and Iodide of Potassium in water, and the mucous membrane is vigorously rubbed with this till bleeding occurs. After this has subsided, a softer brush is used. At the end of about five days, when the inflammation has subsided, the operation is repeated once, and these two sittings are reported to effect a cure.

Ehrman has obtained results in chronic pharyngitis which far outstrip those produced by any other drug or methods of treatment. He employs pure Crystallized Trichloroacetic Acid by means of a probe and cotton wool. This effective caustic (Author's "Pharmacy, Materia Medica, and Therapeutics," 7th Edition, page 489) destroys all diseased membrane without producing any pain or inflammation if cocaine be used previously. It can be applied to the nose and behind the palate. A solution (1 in 3) in Glycerin may be freely painted or swabbed over the granular surface.

At a later stage the Chloride of Zinc Solution (15 to 20 grains to 1 oz.), may be freely applied after local irritation has been soothed by any of the gargles, or sprays, or swabs already mentioned. As a rule, however, it may be said that the gargle is the least satisfactory of all the forms of local applications in the management of chronic pharyngeal affections.

Tincture of Iodine with Glycerin of Alum is a very excellent solution for daily application with lint or a large brush (1 in 8).

Bromide of Ammonium Solution (20 grs. to 1 oz.) has been found very useful in subduing the irritability of the pharyngeal muscles, but the writer has had better results from its internal administration in full doses, the effects being much less transitory than when its local exhibition is relied upon.

The Chloride of Ammonium inhaler is sometimes of the greatest service in the later stages of treatment, and sometimes all through the ailment it affords some relief, especially when laryngeal irritation is a prominent feature.

Syphilitic pharyngitis is to be treated by remedies directed to the primary lesion—Mercury in the early stages and large doses of Iodide of Potassium (20 or 30 grains three times a day) in the tertiary ulcerations. Chlorate of Potassium, 4 drachms, Carbolic Acid, 1 drachm in 20 ozs. Rose Water, is an excellent application or gargle for habitually cleansing the surface of syphilitic ulcers in this region. Where they fail to show any tendency to heal under this mild treatment, the writer is not afraid to touch them over with a brush moistened (but not dripping) with strong Solution of Per-nitrate of Mercury. The solid stick of Nitrate of Silver may be applied, but the mercurial solution used with caution is far better. The brush should never be applied to the neighbourhood of the larynx or to the healthy parts of the mucous membrane.

Iodized Phenol may be used in the same way, or the ulcers, when well within reach, may be insufflated with Iodoform.

The following liquid may be swabbed over the throat upon cotton wool:—

R. *Hydrargyri Perchlor.* gr. j.
 Ammonii Chlorid. gr. vij.
 Glycerini Aluminis ʒj. misce.

Fiat Solutio. M. d. u.

PHIMOSIS.

The treatment of this affection is almost universally regarded as demanding the operation of circumcision. The writer hesitates to speak strongly upon a subject belonging so exclusively to the domain of surgery but the experience of several years surgical practice in a children's hospital, and his repeated opportunities since then of seeing the evils resulting from the elongated and narrow prepuce as they continually present themselves in medical practice has forced him to form a very definite opinion upon the subject.

After practising the operation of circumcision upon numerous occasions, he met with some cases in children and in adults where the operation would not be permitted, and being forced to try the effects of dilatation, he was surprised to find that in every case in which he had the opportunity of testing its value this measure resulted in complete success. In the case of a child whose narrow preputial orifice scarce admits a stout probe a few attempts suffice to dilate the contracted opening by inserting the beaks of a very fine forceps in the closed state, and gradually and very gently separating the handles till the tissues are thoroughly stretched. The ordinary old-fashioned phimosis forceps, opening by means of a finely-threaded screw, answers nearly all purposes. It is almost surprising to find to what extent dilatation may be pushed without causing pain, cracking, or tearing of the prepuce. Once or twice a week is often enough and frequently in young children the prepuce may be painlessly slipped over the glans after one or two trials with the forceps. When this has been accomplished with such ease as to render paraphimosis unlikely, the child's parents may be safely entrusted to periodically draw the prepuce back, and in the case of older children they see to this themselves. In a comparatively short period the elongated prepuce shortens and the writer has seen several cases where a long narrow prepuce after dilatation has been found years subsequently to have almost disappeared, leaving the glans bare as if circumcision had been skilfully performed. In two cases where an extremely narrow opening had existed from the time of birth, and caused no inconvenience till marriage, dilatation was found to effect a permanent cure in a few weeks.

Symptoms of incontinence of urine at night bladder irritation and of stone, depending upon the condition of the prepuce, rapidly disappear after gradual dilatation by the phimosis forceps. These symptoms, however, are rarely caused by the constricted orifice as generally stated. They arise from the irritation produced by the partial or complete adhesion or growing together of the mucous surfaces of the lining of the prepuce and the covering of the glans, and this cannot be remedied till the orifice of the prepuce is dilated so as to permit of the foreskin being drawn back and peeled off the glans by forcible scraping with the finger-nail till the head of the penis is completely bared. Occasional drawing back of the foreskin

in the act of micturition effectually prevents any further adhesion of the contiguous mucous surfaces.

There is no doubt that an early circumcision, as performed by the Jews upon the eighth day before the parts are at all developed, would be a wise law for universal acceptance, but it is often a question if the surgeon is justified in chloroforming and performing a by no means trifling operation upon older children or adults when results almost equally good in many cases may be obtained by painless gradual dilatation.

Acquired phimosis may in many cases be successfully treated in the same way, after the irritation of balanitis has *entirely* disappeared, but where a chancre or warty vegetations are found to be present, there should be no attempt made to dilate, but the foreskin should be slit up and the glans fully exposed by first passing a director through the preputial orifice and cutting with a sharp-pointed curved bistoury or fine scissors through the prepuce at its dorsal aspect. Any useless tissue may be snipped off, and the edges of the mucous and cutaneous surfaces should be brought together by catgut or fine silk sutures.

Where in congenital phimosis the prepuce is *very much* elongated, the ordinary operation of circumcision may be performed, though the writer finds that the superfluous tissue often disappears. Being gradually pulled back it becomes part of the covering over the body of the penis when complete dilatation has been successfully accomplished.

Circumcision may be performed in congenital cases by slitting up the prepuce as just described, but where there is much useless skin the older method is better. The surgeon, measuring the amount which he thinks necessary for removal, while the parts are in their natural unstretched position, by grasping the foreskin between the tips of his forefinger and thumb, applies the blades of a pair of ordinary dressing forceps behind his finger-nails as he puts the skin upon the stretch by drawing it forwards.

Clover's circumcision tourniquet may be used instead of the forceps' blades, which are liable to slip. When the tourniquet or forceps are tightened the part of the prepuce in front of it is shaved clean off with a sharp knife or pair of curved scissors. After removing the blades the skin retracts well backwards, but the mucous membrane, which still is found to cover the glans, is to be slit up well back to the corona on the dorsal aspect by scissors or bistoury. In very young children sutures are unnecessary, the edges of the skin and mucous membrane being held in position by a narrow strip of lint wound round the penis. In older patients the edges of the skin and mucous membrane must be neatly brought together by fine catgut sutures.

The plan of coating over the dressings and keeping them in position by collodion is not to be recommended, as the writer has seen intense pain caused by the removal of the application.

Any simple antiseptic lotion may be used to keep the dressings

moist for three or four days, after which the parts will generally be found to be in an advanced stage of repair.

PHLEBITIS

Absolute rest of the affected limb as the patient lies in bed is essential. Where the veins of the leg are affected, the entire limb from the toes to the trunk should be kept in a state of repose, if necessary, by splints. The limb should be elevated by raising the mattress or palliasso. In mild cases the Liniment of Iodine brushed over the course of the inflamed vein often affords speedy relief. In severe cases Iodine in weaker solution may be once brushed over the course of the affected vein, after which hot fomentations a few hours later on may be tried if the pain be very acute. The writer's routine method of treating severe cases of extensive phlebitis, arising out of varicose veins, is to envelop the entire leg in warm absorbent wool, over which a layer of thin mackintosh is spread so as to cover completely at every point the wool from the toes to the groin. This dressing is kept in accurate position by the even pressure of a skilfully applied woven bandage.

This application should not be interfered with for 24 hours, when the wool is to be replaced by a fresh coating. Poultices are certainly much inferior to this method, and should only be applied when suppuration occurs. A local phlebitis affecting only a limited area should also be treated by absolute rest of the entire limb in order to avoid the detachment of the thrombus, and the application of the ordinary Spirit Lotion (1 of Spt V. Rect to 3 of water) upon lint, which is to be covered with oiled silk and a bandage, affords the best and simplest treatment. A smart Saline purge is often very useful, and Hazeline internally and as a lotion may be tried.

The following may assist in the solution of the thrombus :—

- R. *Ammonia Carb.* ℥ii.
 Spiritus Ammon. Ar. ℥i.
 Potassii Iodidi ℥ii.
 Hazelin ℥ii.
 Glycerini et Aquæ ad ℥vi. *muce.*

Fiat mistura. *Signa*—"Two tea-spoonfuls in a large wine-glassful of water four times a day, after food."

Abscesses must be freely incised as they appear, and attention should be directed to the antiseptic management of any ulcer, wound, or injury to which the phlebitis is secondary.

Where the phlebitis is septic the great danger is that of pyæmic infection from septic emboli. To prevent this the vein should be

ligatured well above the inflamed spot. This having been done, the diseased patch may be excised, or if this be inadvisable, it may be opened and the septic clot removed.

At a later stage oedema and local thickening may be removed by the pressure of an India-rubber bandage. This is much to be preferred to the ordinary elastic stocking. Massage is not to be recommended owing to the risk of detaching clots or thrombi. Strapping the limb with Mercurial Plaster hastens the absorption of effused inflammatory products, and benefit may be obtained from the internal administration of large doses of Iron, Quinine, or Iodides. The rubber bandage should be worn till long after the disappearance of all thickening, and in the case of varicose veins it should be used daily for the remainder of the patient's life.

Blood-letting, leeching, Mercury, and other antiphlogistic measures, are generally contra-indicated, but leeching is sometimes useful at the very commencement of a localised periphlebitis.

PHLEGMASIA ALBA DOLENS.

As this affection is generally found as a complication of the puerperal state the general condition of the lying-in patient should receive careful attention, and no harm can come of the physician insisting upon thorough irrigation of the vagina, and in special cases of the uterus with some mild and unirritating antiseptic solution as weak Condy's Fluid or Boracic Acid, if such have not already been employed, provided always that its application does not interfere with the chief measure, i.e., rest. This is to be as complete and thorough as possible. If the patient has already got up and moved about she must be put back to bed. The position of lying upon the back on a hard hair mattress is the best; by elevation of the mattress or pailasse the limb should be slightly elevated above the level of the trunk.

Where there is marked fever at the onset, a full dose of Quinine, or a diaphoretic mixture containing 3 minims of Tincture of Aconite and 3 or 4 minims of Solution of Morphia, with Spirit of Nitre and Mindererus Spirit, should be prescribed.

Pain will require Opium, but rarely will this be needed in large amount. A good routine treatment will be to put the patient upon a pill consisting of $\frac{1}{2}$ grain Extract of Opium, and 24 grains of Quinine every six or eight hours. A smart Saline purgative should be administered from time to time, and in severe cases the child should be weaned.

Local treatment is of the greatest importance. As a rule this is much overdone. Leeching is seldom required, and irritating applications or blisters are to be avoided. The usual treatment of applying warm or hot fomentations is not to be recommended, nor are poultices advisable or convenient. It may be laid down as a rule that any method of treatment necessitating frequent manipulations or changes of posture of the affected limb is to be condemned. The danger of dislodging clots or thrombi is to be

always kept before the mind of the physician, especially as phlebitis is also commonly present, and for this reason traction of all kinds must be avoided. The best method to pursue is that mentioned under the head of Phlebitis. The limb is to be carefully covered from the toes to the groin with a uniformly thick layer of absorbent cotton wool, after which one large piece of the mackintosh is to be used to cover the entire limb, so as to permit of no part of the wool being visible. Over all a broad soft woven bandage is to be evenly applied. This dressing need not be disturbed for several days if the effect of a poultice be desired, and when it is removed the skin of the limb will be found moist and wrinkled, as if after long immersion in water. As a rule where pain or tension is not very great, this maceration of the limb is not necessary, and the wool may be changed daily. As already mentioned, the limb should be elevated by tilting the mattress. In the great majority of cases the above treatment is all that is required, and if commenced at the earliest stages, much pain and tension will be prevented. When the case is not seen till the swelling and discomfort are at their height, relief may be more quickly obtained by enveloping the limb in a double layer of flannel bandages wrung out of hot water, over which the mackintosh may be adjusted and kept in position by a light elastic or stocking-web bandage. Laudanum, Belladonna, Camphor, or decoction of Poppy heads, or other anodynes may be added to the hot water, but they are seldom required.

As the acute stage passes off the wool is to be retained, but the mackintosh covering may be dispensed with when the limb, painless, doughy swelling has become established, the wool being firmly but comfortably bandaged by a woven fabric.

At a later stage a soft, dry flannel bandage may be applied and renewed morning and night, the limb being occasionally sponged over with a little tepid water, but friction with oils or liniments is to be forbidden for the reasons already mentioned. The patient may now be permitted to leave her bed for a comfortable couch, but exercise of the affected leg is to be very cautiously permitted till all danger of detaching clots or thrombi has passed away. There is considerable difficulty in restraining nurses from rubbing the limb at this stage.

After the patient begins to move about, if the swelling remains, there is no remedy so valuable as the India-rubber bandage applied every morning before getting out of bed, and taken off after she goes to bed at night, when a thin flannel roller may be substituted.

This continuous elastic pressure has been found by the writer to speedily and permanently remove doughy swelling which had existed for many months, and in one case for several years. The continuous current is now of considerable use, and Massage may be most valuable, with the occasional use of Iodine applications for a few days, while the patient keeps her bed. Friction, with

the Lin. Pot. Iod. Cum Sapone, or Cod Liver Oil, is also of great use.

The rubber bandage is infinitely more valuable than the old-fashioned elastic stocking, which should be discarded. The woven rubber bandage, made of material such as is used for the elastic sides of "spring-boots," may be used to great advantage in preference to the pure India-rubber bandage.

Seldom are mercurial dressings or inunctions indicated.

Warm Salt Baths may be tried in very chronic cases, and the Brine Baths of Droitwich are excellent.

Hamamchis and Hazeline, though much vaunted, are of little use in this affection.

Iron in combination with Iodides and small doses of Tincture of Digitalis are useful in the late stages.

PHLEGMON—See Erysipelas.

PHOSPHATURIA OR PHOSPHORIC ACID DIATHESIS.

The appearance of phosphates (triple) in the urine is generally the result of bladder and prostate disease, which furnish the only indication for treatment. In those cases where earthy phosphates are thrown down because the urine is alkaline, the cause will generally be found to be dyspepsia depending upon some marked neurosis. The treatment of the primary affection is thus of chief importance. Dyspepsia, insomnia, and the exhausted conditions arising out of prolonged severe mental overwork or worry, are to receive appropriate treatment.

Change of scene to a mountainous or sea-side region rest of mind and active exercise of the body in the open air, with boating and bathing and a generous animal diet, are the best remedies. Of internal remedies, the diluted Nitro-hydrochloric Acid in full doses is always of considerable value, though its action can only be likely to prove useful by its general tonic effect upon the system. Drugs such as the Mineral Acids, generally fail in relieving those cases where the phosphatic deposit in the urine depends upon the constant alkalinity produced by fixed alkali, nor are there any great reasons for active drugging, as calculi seldom form out of the amorphous phosphate of calcium. The indications, as above stated, are not for chemicals, but for measures calculated to improve the general health.

The same remarks apply to some extent also to those cases where the phosphatic deposit is caused by volatile alkali; but local treatment is of the greatest importance, and Roberts has shown that the injection of 1 drachm of dilute Nitric Acid into the bladder, when diluted with 10 oz warm distilled water once daily, soon dissolved the phosphatic deposit which rapidly formed upon the surfaces of an old calculus which had been crushed with the lithotrite.

The bladder must be brought into a healthy condition, and ammoniacal urine should be remedied or prevented by the most scrupulous cleanliness as regards catheters, sounds, &c., and by the frequent irrigation of the bladder by a weak Nitric Acid injection. Since first using Boracic Acid internally in bladder affections associated with an ammoniacal or putrid state of the urine, the writer finds irrigation by the catheter much less frequently called for. The effect upon the urine of even small doses (8 to 10 grs.) of the Acid by the mouth is generally very satisfactory. There remains, however, a small number of cases of true phosphaturia in which the actual amount of earthy phosphates excreted is largely increased. To this group Tessier has given the name of phosphatic diabetes, and the treatment which gives greatest relief to the severe back and visceral pains is Morphia or Codeia given as in saccharine diabetes, and followed by hydropathy.

Massage may be tried, and every means whereby the general condition of the patient and his body weight can be improved must be resorted to, as phthisis is very liable to supervene. Cod Liver Oil, feeding with peptonised foods and fats, and a diet composed largely of milk, accompanied by the use of tonics like Strychnine, Dilute N.-Hyd. Acid, seaside residence, &c., should be tried. All diuretic agents as alcohol, digitalis, &c., must be avoided.

Creosote in capsules and Salol in cachets also give excellent results where the Boracic acid causes stomach irritation.

PHOSPHORUS POISONING—See Poisoning.

PHTHIRIASIS.

The treatment of the cause of this affection is described at length under Pediculi. After means have been undertaken for the destruction of the parasites, the excoriations, eczema, impetigo, and other lesions produced by scratching or by the irritation of the insects, should receive appropriate treatment. Their management is detailed under the heading of each affection, and appropriate remedies must be used when they do not rapidly subside after the destruction of the pediculi.

PHTHISIS.

The treatment of pulmonary phthisis requires more space than can be devoted to it in the narrow limits of the present volume. Hence only an outline of the most approved methods of dealing with the disease will be attempted. At the outset the question must be answered—Is phthisis curable? The weight of all respectable authority is every year becoming more and more emphatic upon this point, and a decided answer in the affirmative must be given by every observer who approaches the problem with an open mind. As already pointed out in discussing the

treatment of various other affections, the secret of success often depends upon the spirit in which the physician and patient enter upon the struggle with the disease.

Until within the past few years the discovery of a tubercular deposit in any region of the body was almost universally regarded as leading to a fatal issue. The recent strides made in abdominal surgery must convince the most sceptical that extensive tubercular disease of the peritoneum which has been seen and handled by the surgeon has been proved beyond doubt to be curable in many instances. The physician who regards as a case of mistaken diagnosis every case of pulmonary phthisis which has yielded completely to treatment, is certainly not keeping abreast of the tide of progress and knowledge.

The successful treatment of pulmonary disease may be, upon the other hand, also seriously retarded by the blind belief in the efficacy of many drugs which, at the best, can only be said to possess feeble action over the affection. Nevertheless, the impartial observer must be convinced that very substantial progress is being made since the days of leeching, blistering, and antiphlogistics.

Drugs should play a very minor part in the treatment of phthisis. The main reliance must be placed in hygienic measures, as soon as the family history, symptoms general and local, and the physical signs warrant the physician arriving at a diagnosis of the disease.

The writer is accustomed to keep ever before his mind in dealing with phthisical patients the facts demonstrated by Metschnikoff and applying these to the treatment of phthisis. He regards the question of its cure as being one of "phagocytosis." It will probably be demonstrated soon that the agent which so modifies the action of the phagocytes as to secure the proper performance of this process will be the one upon which our hopes are to depend for destroying the disease.

The clothing of the phthisical patient in this country, if left to his own choice, is almost certain to be injurious. He selects heavy garments, and wears too many of them, so that the least exercise induces perspiration and increases the risk of chills. Woollen garments should be worn next the skin, and in winter these may be changed for heavier or thicker ones of the same material. They should be changed often. In very severe winters a chamois vest may be worn, but if so, it is better to have it perforated; it may be worn over a light merino fabric.

The fabrics should be such as will speedily absorb perspiration, and it is much better to arrange for moderate extremes of temperature by overclothing which can be easily removed. A light overcoat, which can be readily put on and off in summer, will enable the patient to do with less underclothing, and in this way continual overheating and chills may be avoided after exercise. The feet and legs should be protected against damp and cold. It is more difficult to arrange the clothing of women, but such directions should be given as will lead them to sacrifice their ideas

of fashion to their health, for, although a matter of detail, it is a very important matter. Too much clothing is often a more serious mistake than too little. In driving or travelling the warmest coverings are essential.

Food is of far more importance than medicine and practically there need be no limit set to its amount. As much as the patient can be tempted to swallow may be administered. A well-mixed and varied diet is the best for a consumptive patient in the early stages. It should be carefully cooked and served in the most tempting fashion, and the writer has sometimes felt that a good cook was of more importance than a therapist. Fats should, when possible form an important item in the daily food, and abundance of milk, eggs, and butter is generally within the reach of all, and they do not demand in their preparation much scientific knowledge or cookery. When the temperature is elevated, and the digestive organs weakened, the patient may have to rely entirely upon a milk diet, and experience has proved that this of itself is a most valuable dietary in all stages of phthisis. Some patients can take cream. To live upon milk 4 pints, at least, in the 24 hours will be required to meet the demands made upon the system, but as the great aim in dealing with phthisical patients is to administer more than is required to meet the waste, and to so improve the nutrition as to considerably add to the body weight, a larger quantity will be necessary.

In some of the "milk cure" establishments more than double this amount is given. When the patient objects to raw milk it may be cooked in various ways, or mixed with Kali or Lime water, or made into whey or Koumiss. As already stated, good butter, if turned slightly acid is one of the most valuable and palatable of foods, and is often relished and taken in great quantity when every other form of milk is distasteful. A favourite beverage with most drinkers is to mix equal quantities of fresh cow's milk and butter-milk together. Milk warm from the cow, is believed to be more digestible than the cold liquid. A little good rum added is a great improvement. Jaccoud advises phthisical patients to repair twice a day to the cow-house to drink the milk warm from the milking pails, and to inhale the moist sedative atmosphere of the place for some time, so as to have laryngeal and bronchial irritation soothed.

Where the digestion is weak, the milk may be peptonised. Rennet is often relished when this is distasteful.

The milk of the mare, ass, goat, and sheep may be used, and the first two kinds of milk are easily digested. The Koumiss made from the fermented milk of the mare is a highly-prized Russian remedy for phthisis. The writer has had great satisfaction from home-made preparations, and when patients are taught to make their own beverage from materials which they know to be free from any objection they often take it when they object to a foreign article, like the Russian Koumiss or Kehr.

Either of the forms given upon page 556 of the 7th Edition of the writer's book on "Materia Medica and Therapeutics" may be used. That of Ponomaroff is sooner ready for use.

In the absence of yeast, a palatable and highly nutritious beverage may be prepared by mixing one part of fresh rich buttermilk and one part of water with eight parts of cow's milk adding a very little loaf sugar, putting the mixture into a loosely-corked gallon jar, leaving it in a warm, but not hot, place beside the fire, where it may be frequently and briskly shaken, and in 36 to 48 hours it is ready for use as a pleasant, sharp-tasted thick liquid, which slightly effervesces. Some little skill and experience are required in producing a uniform result, and the patient should not give it up if the first and second results are unsatisfactory. After the first batch of this artificial koumiss has been successfully prepared the use of buttermilk may be entirely dispensed with, as an equal bulk of the koumiss liquid can be used instead, in the preparation of each subsequent quantity. Some patients succeed best by leaving out the sugar entirely, and by shaking the mixture very seldom during the first 24 hours. Where a phthisical subject takes to this home-brewed koumiss, as a rule all difficulty in feeding is overcome; but the article commonly known as buttermilk in England will not make koumiss. The artificial Kefir mentioned in the volume above referred to is made upon a somewhat similar principle.

In the intervals between feverish attacks, animal food in abundance may be given. Beef tea is admissible when little else can be got down, but too often phthisical patients are starved upon it.

Raw meat is a favourite dietetic agent in treating phthisis in France. The meat is passed through a mincing-machine, scraped with a knife, pounded in a mortar, or rubbed through a sieve or rolled into pellets and covered with chocolate. (See reference upon page 730 to this treatment.)

Fish, poultry, game, oysters in abundance, and, in fact, every food which is considered easy of digestion and highly nutritious may be allowed without stint, always provided that farinaceous, fatty and fat-forming stuffs are allowed a good place. Weber objects to potatoes and all foods which contain potash salts, which, he argues, encourage the growth of the tubercle bacilli.

Malt Extract is of great value, but the writer prefers to administer it in combination with Cod Liver Oil, which will be referred to when speaking of drugs useful in phthisis.

The system of forced feeding over feeding, or "oralimentation" introduced by Debove, consists of introducing a soft rubber stomach-pump tube and filling the stomach with liquid food, as milk, broths &c. In this way he finds food is always retained when everything is rejected after swallowing. Meat dried and powdered is mixed with milk till a uniformly fluid compound is obtained, which is given till finally the equivalent of 3 lbs. of meat is administered daily by the mouth without the tube. Excellent

results are reported from this treatment, and Débove maintains that the *suralimentation* augments combustion, and so enriches the blood as to prevent the growth and development of the bacilli. From the writer's point of view, he would explain these results by supposing that the *suraliment* method stimulated phagocytosis.

The question of Alcohol in large quantities in the treatment of phthisis has led to sharp differences of opinion. Flint mentions the case of a young woman, where 20 ozs. of whiskey were used daily for two years, and the patient recovered. As a rule, it may be said that stimulants are not advisable in the early stages, except where experiment proves that they increase appetite and assist digestion. They should always be administered along with the food, and any good, sound light wine may be permitted.

In the stages of the disease where softening of the lung has occurred, whiskey may be allowed in fair quantity, and if mixed with the patient's milk any reasonable amount may be allowed without danger of doing harm. By giving it in this way, cough may be eased diarrhoea checked, sleep produced, fever diminished and waste retarded. It is obvious that in the class of case referred to, a fatal issue is most likely to be the outcome of the disease and therefore the moral objection to creating an alcohol habit is not so serious as under other circumstances.

Fresh air is of almost equal importance to food, and it is perhaps to the recognition of this fact more than to anything else that the improvement in the management of phthisical cases has been owing. Dr Henry MacCormac, by his early appreciation of the evils attending the inspiration of re-breathed air, has done more for the prevention and treatment of pulmonary consumption than any other pioneer of progress.

Day and night the most free ventilation of sleeping and sitting rooms, or apartments in which the patient is carrying out his daily avocation, is of the utmost importance. This is a difficult part of the treatment to carry out effectually, as phthisical patients owing to their being constantly too heavily clothed, soon become abnormally sensitive to currents of cool air, and the horror of "draughts" or "catching cold" is a bugbear that must not be permitted to take entire possession of the patient. The writer is inclined to think that the tendency to catch cold, which is undoubtedly present in most phthisical patients, is engendered by the excessive clothing generally worn. It is rare that the patient can be induced in this climate to sleep with the bedroom window open all night, and the physician should insist upon a free egress of the vitiated air. A tale ventilator put into one of the chimney flues, and a Toban's tube, or Tail's thermic ventilator, are most valuable additions to the host of remedies. The situation of his bedroom should be such as will prevent the exposure to cold east or north winds, and his residence should be upon a dry sandy and not upon a moist clay soil.

All his available spare time should be spent in the open air, and by wise wrapping in suitable clothing he should so continually accustom himself to an outdoor life as to be able to expose himself without danger, even in unpromising weather.

All sorts of outdoor games, amusements, and exercises should be freely encouraged, and whatever tempts the patient to remain as short a time as possible in the house should be cultivated. The amount and kind of exercise must of course be tempered to the condition of the patient, and where there is a constant tendency to hæmoptysis, rowing, cricket, lawn tennis, or other active exercise must give way to sailing, driving, or leisurely walking. In city clerks and those leading a sedentary life, where open-air exercise must be very limited, if found in the early stages gymnastic exercises in a lofty, well-ventilated gymnasium are often of much value, and Williams advised these to be pushed even to the extent of producing emphysema in the diseased lung, as others have advocated bugle or trumpet practice with the same object in view. Horse-riding or cycling may be freely indulged in.

In those cases where cure has followed change of occupation and climate the factor probably deserving the most credit has been the open-air life which has been thus forced upon the patient, and of all the hygienic measures advocated in the treatment of pulmonary consumption this must be regarded as the most vital.

Therefore, where possible, the patient should be induced to give up his occupation for one which will allow him the *longest time in the open air*, and habits of life in the wealthy which interfere with outdoor exercise must be given up if the disease is to be checked.

It is sometimes astonishing to observe the results which follow upon a patient being thus lifted out of his unhealthy environment, and one might say that, given a case of phthisis in the early stage, the prognosis will chiefly depend upon the extent to which the habits and environment of the patient are susceptible of improvement. Hence the necessity of the most rigid investigation into every surrounding of the victim of phthisis in the early stages.

There can be little doubt that, as pointed out recently by Williams, the open-air treatment of phthisis does not receive the importance in England which it deserves. Though the climate is variable, by sheltered open corridors or balconies much might be done to enable the patient to spend most of his time in pure antiseptic fresh air. The writer is accustomed to insist upon phthisical patients being out, if possible, the entire day, and in wet weather he selects a room with very large windows, which the patient should keep open all day long.

Climate is a factor of great importance, and as improved methods of travelling have brought temporary or permanent change of residence within the reach of most patients, the question of climatic treatment is daily becoming more important, and many volumes have been dedicated to the elucidation of this valuable means of

combating the disease. Unfortunately, much difference of opinion exists amongst those who have given special attention to the subject of health resorts regarding the relative value of various localities, and it is therefore most difficult to lay down general rules for the guidance of practitioners in selecting the best climate for individual cases of phthisis.

Looking at the subject broadly, the writer is accustomed to formulate for himself the general rule that *the climate which affords the greatest facilities for spending the largest amount of the patient's time in the open air is the one most likely to lead to the best results in most cases.*

It is, therefore, wise in approaching the climatic method of treatment to regard it chiefly, but not altogether as a mere variation of the open-air or out-door plan of treating phthisis. Climate will generally be found to accomplish little if the patient carries with him his sedentary habits late hours and dislike to open-air exercises, and it is the duty of the physician to impress upon him forcibly that it is not the climate *per se* that is the cure or only factor, but that he must avail himself to the very fullest extent of the opportunities of spending all his time in the open air, which is impossible in his own variable climate.

During the last few years enormous importance has been attached to the so-called "new cure" for consumption—i.e., the open-air and over-feeding cure. This has apparently marked a new era in the therapeutics of this disease. Its name implies the two chief factors in this treatment. The importance of these have been long recognised by all authorities on phthisis, and the reader will probably be surprised that not a single alteration has been made in this article, beginning upon page 720, up to the commencement of this paragraph, save that a dietary of Yeo's has been ~~erased~~ out for want of space. The matter is reprinted exactly as it was in the first edition of the present work, written in 1890 save the immediately preceding paragraph, which appeared in the 1882 edition. The italics are also the same, and this is done intentionally to show that there is really nothing new in the ordinary sense of the term in the treatment. The article might almost be taken as a detailed description of the principles carried out in the sanatoria erected yesterday. Nevertheless great progress has been made since 1890. The profession and the public have had their enthusiasm aroused by the successes achieved by the open-air treatment and we are within measurable distance of seeing open-air sanatoria erected for the poor phthisical victims of every large manufacturing city.

In the various places where this treatment has been carried out the patients live and sleep and eat in the open air. The system of revolving shelters, which can be turned from the wind and enable them to be practically in the open air in most unpromising weathers. The splendid double tent devised recently by Mr. Wilson (of Belfast) enables the patient to live and sleep out all the year

round in any climate. Those unable to exercise on account of fever, &c. have their beds brought out to the open, and get both air and sunshine, and the writer can testify to many remarkable improvements and arrests in the disease. The over-feeding is generally pushed to its greatest limit, and very great increase in weight sometimes results. All this is accomplished for the most part without drugs, and one thing has been demonstrated, that climate has little to say to the good results, as these have been sometimes accomplished in districts where phthisical patients were formerly regarded as doomed if they remained in them.

Whether we attempt to explain these results on the theory of phagocytosis, or call it by some other name, every recent step in the progress of the therapeutics of phthisis proves that our hope of ultimately overcoming the disease does not lie in the administration of bactericidal drugs, or specifics intended for the destruction of the bacilli, but in those agents which by improving the nutrition of the body will *increase the resisting power of the patient*. Osler has quite recently stated that the arrest or cure of tuberculosis is a question entirely of nutrition, or of the measures by which the general nutrition of the body may be encouraged, and the chief of these are food, pure air, and sunshine.

To return to the consideration of climate, it will be seen that the facilities for the treatment by open-air sanatoria have rendered the question of climate a much less important one than before.

The advantages obtained by a long sea voyage are, perhaps, greater than those resulting from a residence in any health resort for a similar period of time, and upon the whole it is deservedly held in the highest esteem as a therapeutic agent. A long voyage in a good sailing ship from England to Australia is a powerful remedy in restoring the phthisical patient to health. It is here that the maximum amount of a perfectly pure atmosphere can be enjoyed from early morning till late at night. Exercise can be had all day, and Charteris advised that a pedometer should be used to mark the mileage which should be two miles before breakfast, three before luncheon, three before dinner, and two before turning in at night. This is worth noting, as there is danger of the patient being seized with that listless idleness which sometimes paralyses every tendency to exertion when at sea.

Hæmorrhage is no barrier to the ocean voyage, and except the consideration of discomforts from the absence of home luxuries, isolation from friends, and the risk of the complications and exacerbations which are liable to happen also upon land, even advanced cases of the disease may be safely committed to the risks of an ocean voyage if the patient be informed of his exact position. The practice of sending patients away in the last stages of the disease in search of health when death is soon inevitably near is to be condemned, but some patients, who, in the advanced stages of phthisis, take the notion of a long voyage

and persist in carrying it out in spite of the remonstrance of the friends and physician often return wonderfully improved. Cases of limited first or third stage of hæmorrhagic phthisis when the patient's strength is unequal to much exercise, and who has suffered from close confinement in a crowded city, is, in the opinion of Williams, those most likely to be benefited by a sea journey.

The ocean journey may be undertaken in a sailing vessel about the middle of September, so that the return of the patient may fall in with the early summer, after the disappearance of the dreaded East wind. It does away with the difficulty of visiting a health resort unless this problem will require to be met after return.

Where a journey to Australia or New Zealand is out of the question the health resorts nearer home may be considered. Bournemouth and Ventnor are the best suited for the majority of cases, and it is the experience of the writer that excellent results may be obtained from a winter in the first mentioned, often better than when the patient has to put up with the fatigues and inconveniences of a longer journey. The dry sandy soil of Bournemouth, the shelter which it obtains from the prevailing winds and the beneficial influence of its neighbours, pine plantations, render it a valuable resort to those who cannot go further; Ventnor is to be preferred where a marine atmosphere is desired; Torquay, where a moist sedative air is required in the presence of extensive bronchial irritation; Rothesay is the best of the Scottish winter resorts. In most of these places sanatoria have been erected in recent years.

Glengarriff and Rostrevor are the chief winter resorts available in Ireland, and they afford excellent climatic advantages. The sanatorium in Rostrevor is built on one of the most perfectly suitable spots in the British Isles, and has the rare advantage of being cool in the summer and warm in the winter.

All the advantages of the open-air and over-feeding treatment can be now obtained at home as well as at Nordrach.

The dry climates of Egypt, Tangier, Algiers, Morocco, the Riviera, Malaga, the Cape, Tasmania, and Australia, have been continually proved as of the greatest benefit to the consumptive.

Dr. Lindsay points out the dangers to which consumptives may be exposed in the Riviera, owing to the prevalence of the debilitating "*mistral*" wind. He, therefore, prefers Mentone as being the most sheltered beyond comparison of all the Riviera resorts, and especially suitable where there is an irritable bronchial mucous membrane, and an intolerance of wind. San Remo, though less sheltered, is drier, warmer, and more equable.

The moist temperature of Madeira and other relaxing or sedative marine climates is not indicated, except where catarrhal conditions prevail, or where laryngeal complications exist.

Arcachon and Biarritz are excellent autumn resorts, and the

patients can leave them and proceed to the Riviera, Algiers, or Madeira, as winter sets in.

The tendency of modern authorities is towards giving the *high altitude* treatment of phthisis the first trial when climatic therapeutics has been warranted by the history, symptoms, and physical signs. The extraordinary purity of the air and the low barometric pressure tend, with other considerations, to produce a most beneficial effect upon the lung tissue, which is the seat of disease, as well as to produce hypertrophy, and even vesicular emphysema and expansion of the chest, as believed by Williams.

The *stillness* of the air, its great *purity*, *rarefaction*, and *dryness*, the absence of fogs and the prevalence of ozone and bright sunshine, render Davos a favourite resort for the victims of phthisis. Even in the depth of winter the patient can safely sit out in the still pure atmosphere in bright sunshine, when the thermometer is below freezing point, and at night he can sleep with open windows.

Appetite increases, the lungs expand, night sweats and fever subside, hæmorrhage is less likely to occur, and many patients return without any symptoms of the disease, having also left their physical signs behind them. The rarefaction of the air is, of course, a most important factor in producing these good results. Dr. Lindsay lays stress upon the inadvisability of sending patients to Davos who are not capable of supporting and responding to the highly *stimulating* climatic conditions prevailing there. Where sedative measures are indicated, low-level climates should be selected.

By the majority of authorities, the following classes of cases should not be sent to high-level resorts. —

Patients with serious cardiac or valvular lesions, much bronchitis, emphysema, where the symptoms are acute or the fever high, where there is laryngeal or intestinal ulceration, where the disease is so far advanced as to prevent exercise, also the old and very young had better remain in low-level regions. Those of very excitable temperaments, in which insomnia is marked, and those suffering from albuminuria, should not try the high altitude, unless they have had previous experience of it.

It is better that the ascent should be gradual, and early in September is the best period for reaching Davos. After the expiration of six months, the patient may safely move towards the sea level, to return to Davos again in the early winter, if necessary, or he may spend his summer with great advantage in the Engadine, or Weisbaden, Baden-Baden, or Geneva.

The Peruvian Andes, Denver, and Rocky Mountain resorts are also much valued.

Santa Fe de Bogota, in Granada, is an ideal high altitude resort, in which the patient need never feel cold.

Bloemfontein, in the Orange River Colony, and many spots in the Transvaal, are also resorts which have given excellent results,

but they are only suited to those whose strength and vigour are but slightly impaired by disease, as the journey is rough and tedious. Camping out in these regions is a practice which, if the patient can follow it, is sure to lead to the best results which can be expected from climatic treatment in the earliest stages of phthisis.

The treatment of phthisis by drugs, as already stated is of considerably less importance than its management by the hygienic measures already enumerated. This statement would, perhaps, be universally accepted if Cod Liver Oil were included as a food amongst the hygienic remedies. Cod liver oil if regarded as a medicine, butter has, however, quite as good a right to rank as a medicine, stands at the top of the list. Space will not permit of a discussion upon the various theories of how it acts in phthisis. Suffice it to say that it is more easily absorbed than any other oil or fat, and that it possesses the power of aiding the assimilation of other foods, which would not be absorbed except in its presence.

The surprising results following the inunction of cod liver oil over the abdomen of children suffering from abdominal phthisis and wasting diseases has been already mentioned. (See page 528.)

The methods by which the oil is dispensed or compounded in order to render its disagreeable taste and smell less obvious are legion. As a rule, the perfect emulsions are made by sacrificing the therapeutic value of the oil. The writer has practically abandoned all emulsions and compounds, and prescribes the oil in combination with the Extract of Malt, the most perfect and efficacious of all restoratives in wasting diseases. Occasionally its viscosity turns fastidious patients against it, but this is generally remedied by persevering with it for a time. The oil should be given always soon after food, and it is a good plan to be content with a small dose at bed-time only, for a few nights, after which it may be given three or four times daily. A tea-spoonful is enough to begin with, but half an ounce of the oil or a very large table-spoonful of the mixture of oil and malt extract should be administered after each staple meal. The oil may be given with pancreas by the rectum. (See below.)

Febrile disturbance, as evidenced by a moderately high temperature and turned tongue, is a barrier to its use. It is a mistake to force it under such circumstances, the best plan then is to get the digestive organs made right first with a simple saline mixture like the following which is a good formula for the sub-febrile troubles arising during any stage of phthisis.—

R Potassi Bicarbonatis ℥vi.
Liquor. Morph. Hydrochlor. ℥j.
Aque Lauracerasi ℥ii.
Aque Destillate ad ℥viii. misce

Fiat mixtura. Signa—"One large table-spoonful with much fresh lemon juice, every four hours, to be taken until effervescing."

Malt extracts have been used, and they are, doubtless, of value in assisting the digestion of starchy foods; but if the combination of oil and malt extract already mentioned is tolerated by the stomach there is no necessity for further use of these drugs.

Pancreatic Emulsion, containing an emulsified and pancreatised animal fat, is highly recommended, but to most patients it is objectionable, and the writer has ceased to use it. Where a pancreatic ferment is considered necessary or advisable to supplement or assist the human secretions in their digestive functions, Trypsin, Pancreatic Liquor, or Fairchild's Pulverized Extract may be used for mixing with the food. Weir-Mitchell's method of administering cod liver oil and pancreas is the best of all if the patient can be got to take the trouble to use it, and it is an excellent plan where the oil cannot be tolerated by the stomach. Enough of water to cover 8 oz. of chopped beef pancreas is allowed to stand in a warm place for an hour. It is then squeezed through a towel, and 1 oz. of the juice is rubbed up with $\frac{1}{2}$ oz. of pale cod liver oil, and injected three times a day into the rectum.

The Hypophosphites are believed by many to possess great efficacy in the early stages of phthisis, and the various quack syrups which are much used by the public are not without their therapeutic value, but, as a rule, those whose composition are known when prepared by any respectable chemist, will be found to give more satisfactory results than the highly advertised nostrums. The Syrupus Hypophosphitum Compositus of the B.P.C. Formula is an excellent and reliable preparation, as is also the B.P. Ser Calen Lactophosphatis. The quinine and strichnine may be omitted in the first-mentioned compound when the effects of the hypophosphites of iron, calcium, manganese and potassium only are desired. When administered in conjunction with cod liver oil, there can be no doubt that these drugs are most valuable in the early stages of phthisis and in very chronic cases.

The treatment of pulmonary phthisis by drugs since the discovery of the bacillus of tubercle is one of ceaseless activity, and of incessant changes. Up to the present, unfortunately, little progress can be reported in the treatment of the disease by germicides, though every known substance whose action is inimical to the life of minute organisms has been administered. Of all these trials, the best results have been obtained by Creosote. The writer has used it for many years, and can testify to its great value in relieving cough, lessening expectoration, lowering fever heat, checking night sweats, improving the appetite and digestion, and diminishing diarrhoea.

The reports of innumerable observers at home and abroad prove that in creosote, when properly administered, we possess the best drug for the treatment of phthisis. An examination of

the reports of most of these observers will show that they have given much larger doses than are usually administered in this country, 10 to 30 minims being often administered for long periods.

Guttmann found that the tubercular bacillus grows but feebly in a 1 to 4,000 culture with creosote, and he calculated that the ingestion of 15 grains daily would charge the blood to this extent. It must be remembered that the bacilli probably are already struggling to maintain an existence in the body against odds created by the vital agencies always exercising a hostile influence against intruders; and it is possible that a small amount of a drug like creosote introduced into the system might, under such conditions, be able to turn the scale against the parasite.

It is more probable, however, that the drug may exert a germicidal influence in the body, and that all its beneficial action may be owing to its effects upon digestion, assimilation, or other vital functions which lead to a healthier or more resisting condition of the blood and tissues, thus is the view of most authorities. It is also probable that the drug enters into chemical combination with the toxins produced by the bacillus, and neutralises their actions on the body.

Pure beechwood creosote only should be used. This is now easily obtained in elegant small soft capsules, each containing one to five minims. Many authorities object to the capsule on the ground that when it empties itself in the stomach a localised active inflammation must result. This is a mistake. As the capsule slowly dissolves, its contents gradually mix with those of the stomach; and even when given fasting no harm can result, much less can injury be likely to follow when the capsule is given along with or after food. The writer has given these capsules very frequently in gastric affections and often in ulcer of the stomach, when no food had been taken for days, and he never saw the least irritation or other untoward result follow, and he believes the capsular form to be by far the best method of administering the drug. It is unfortunately rather expensive, and for this reason it is outside hospital extern practice.

The pilular form is often, or generally, unsatisfactory, and a mixture containing the drug is most unpleasant. The following formulæ may be useful —

R. *Creosoli Purificat.* ℥℥iv.
 Spir. Cinnamomi ℥iv.
 Tinct. Aurantii ℥iiss.
 Glycerini q.s. ad ℥iv. *misce*

Fiat mistura *Capsul cochlearium minimum ex paululo*
aquæ ter in die p.p.n. post cibos.

Keferstein dissolves 45 minims in 1 oz. of Tincture of Cinnamon, of which 50 drops may be taken in half a cup of warm milk or a little wine. The formula for his pills is better; they should be coated with gelatin:—

R. *Creosoti* gr. lx.
Pulv. Rad. Althea
Pulv. Rad. Glycyrrhiza ana ʒiiss.
Mucilaginis Acaciae q. s. *misce.*

Fiat massula et divide in pil. cxx.

Martindale's formula is the best for the administration of the drug in the pilular form. He makes a mass of equal parts of creosote and powdered curd soap by heating on a water bath. Each 5 grain pill will contain 2½ minims of creosote.

Guaiacol is the chief therapeutic constituent of pure beechwood tar creosote, in which it sometimes exists to the extent of 90 per cent. Chemically it is the monomethyl ether of catechol or pyrocatechin, and is less objectionable than creosote in taste and odour. It can be had in capsules, and sometimes may be tolerated when creosote disagrees. It may be given in pill, mixture, or capsule. The usual method is in solution in some spirituous liquid or tincture, as in the case of creosote. 10 minims is a fair dose, which may be elegantly administered in sherry or tincture of orange-peel. Many authorities give up to 60 minims daily, and Poggi gives 20 mms. with a table-spoonful of Cod Liver Oil three times a day for months.

Carbonate of Guaiacol is a tasteless powder which has been highly lauded; the writer has got good results with 15 grs. three times a day in wafer papers or in milk, twice this amount is given. It is known also as Duotal.

Styracol or Cinnamate of Guaiacol, in 15 grain doses, is also recommended. It is, however, considered more valuable in intestinal tuberculosis. The same remark applies to Guaiacol Salicylate, which is given in drachm doses.

Guaiacetin, Geosote, Guaiperol, and other guaiacol derivatives and compounds are lauded, but none possesses any virtues which are wanting in creosote.

The internal administration of Creosote may be easily carried out at the same time that cod liver oil and hygienic measures are being used. Indeed, some physicians mix 2 minims of pure Creosote with two drachms of the oil for administration three or four times a day, after meals, and double this quantity can often be taken without producing nausea or disgust.

The creosote treatment is advantageously assisted by inhalations of the drug. These will be referred to later on in speaking of the

administration of remedial agents by the respiratory tract. It has also been given subcutaneously.

Bourget carries out the creosote treatment to the fullest extent by what is known as the "intensive method." By this plan the patient's system is saturated with the drug through various channels. Thus, guaiacol is given by the mouth, dissolved in wine in summer and in cod liver oil in winter, till about 1 gramme (15 grains) daily is gradually reached. Where it causes nausea and sometimes even when it is well borne, he alternates the mouth method with that of rectal injections. At the same time every night a mixture of Creosote and Cod Liver Oil (1 in 10) is rubbed into the skin over the chest and armpits and abdomen whilst as often as possible during day and night creosote is sprinkled upon an inhaler. Guaiacol has been smeared over the skin, but serious collapse has followed its use in this way.

Striking results have been reported from the hypodermic injection of from 1 to 3 cubic centimetres into the suprascapular fossa of a mixture of Guaiacol and Iodoform in sterilised olive oil and vaseline each cubic centimetre of which contains 1 centigramme of iodoform and 5 centigrammes of guaiacol. Sweating and rise of temperature follows each dose, but the reaction is not marked. The general condition improves, cough and expectoration are lessened whilst cavities dry up and cicatrise. In the later stage of phthisis cough and expectoration are also lessened, whilst night sweats and fever may disappear, and the number of the bacilli in the sputum undergoes diminution.

Hudeod affirms, after a most extensive experience, that Creosote is best administered by the rectum, and this is a most valuable method, and at once does away with all difficulties arising from its taste. 30 minims mixed with 1 oz. Cod Liver Oil and yolk of egg or with a table-spoonful of Whiskey and 4 oz. water may be injected once or twice daily. Simon injects Creosote, Salol and Iodoform in olive oil.

Many modifications of the Creosote treatment are now being carried out. Carbonate of Creosote, a syrupy liquid is given in tea-spoonful doses, and Benzocol in 5 to 10 gr. doses, this latter drug is vaunted for its additional expectorant qualities. Trioxen (potassium-guaiacol-sulphonate) is one of the latest Creosote compounds which has gained a high reputation. Menderson has obtained very striking success with it. It is quite odourless, inodorous, and pleasant to taste and may be given safely in such amounts of 60 grs. It is the basis of the liquid known as Sirollin.

Sulphur in various forms has been long employed as an antiphthisical agent, and since the discovery of the bacillus it has again come to the front in many new methods. The old plan consisted in the administration of the crude drug by the mouth, but by the administration of any of the sulphur waters and a residence at some of the natural sulphur springs was considered and is still

considered to be highly efficacious. Sulphur is an excellent expectorant, and is partly excreted by the bronchial mucous membrane. The writer has long praised the Onion (which contains much sulphur) as one of the best known expectorants. Garlic acts in a similar manner, and Cavazzani gives 1 to 2 drs. as the daily amount, and reports most hopefully of its effects in 200 cases. Ichthyol, owing to the amount of sulphur contained in it, is also an agent of great value; up to 1 dr may be given daily in capsules. Sulphur seems to some extent to fulfil Brunton's ideal of a substance which should be looked for, and which would undergo slow decomposition in the intestine, or in the body generally, and give off slowly and constantly volatile antiseptic products to be excreted by the lungs. (See page 94.)

Hitherto it has not been administered in such a way as to give hopeful results, though Witherle believes he has influenced the disease by giving small doses of the Sulphide of Calcium ($\frac{1}{2}$ grain in pill) every hour till the system is saturated.

The apparently barbarous method of Bergeon, by which large quantities of Sulphuretted Hydrogen diluted with Carbon Dioxide were administered by the bowels, can hardly be said to be at present regarded as a justifiable treatment, and the same remarks apply to rectal injections of plain CO_2 .

Sulphates and Hyposulphites, with inhalations of Sulphurous Acid, have been used upon the same principles.

Arsenic has been tried in phthisis. Brunton believes that by increasing the tissue changes in the epithelial contents of the alveoli it assists in rapidly breaking up and removing effused inflammatory products, and so prevents the tubercular bacillus from finding a suitable nidus, and thus the risk of converting a catarrhal consolidation into phthisis is prevented. It is only in the early stages of phthisis that the remedy is likely to do any permanent good, and notwithstanding the reports of decided successes its administration should not be allowed to interfere with the exhibition of the more important hygienic measures already enumerated. In the later stages it sometimes checks the night sweats, and seems to have some effect upon the temperature when this is not of a very high type. Some suppose that it benefits the sweating when this is depending upon or associated with a subfebrile temperature. It may with advantage be combined with Strychnine and Iron. Cacodylate of Soda can be given in large doses hypodermically and by the rectum. (See under Anæmia, page 45.)

Mercury has been advocated, and some sanguine therapeutists believe that in this direction lies the hope of the ultimate victory over the bacillus of tubercle. All the methods of administering Calomel, the Bimodide, and the Perchloride for phthisis are now steadily falling into disuse.

Nuclein derived from yeast cells is believed to greatly increase the bactericidal power of the serum, to increase leucocytosis, and

powerfully stimulate phagocytosis. It contains a large percentage of phosphorus. The best available preparation is the 1 per cent. solution of Nucleinic Acid of P. Davis, which is given in doses of 30 minims hypodermically. The remedy has been tried in this country with varying success.

Thymol, Menthol, Myrtol, Salol, Aristol, Oil of Cloves, Eucalyptus Oil, Naphthol, Balsam of Peru, Aniline, Ozone, Oxygen, Cinnamic Acid, Peroxide of Hydrogen, Carbolic Acid, Phenyl-propionic and Phenylacetic Acids, Mullein, Homeriana, Helenin, Sulphocarbolates, Benzoic Acid, Chloride of Calcium, Chaulmoogra Oil, Terebene, Chloride of Sodium, Salicylic Acid, Iodoform, Turpentine, Iodides, and Tannin have each one lately been reported by different observers as having special or specific action upon the bacilli when administered internally. There is no proof of any specific action of these agents on the tubercular bacillus in the lung.

Hetol.—Landerer, however, after 15 years' experience with Cinnamic Acid, maintains that it produces an intense phagocytosis, and that it also has a bactericidal action. He injects into a vein or muscle $3\frac{1}{2}$ oz. of a liquid containing 7 grs. Cinnamic Acid, 150 minims Almond Oil, the yolk of one egg, and 7 per cent. Saline solution to $3\frac{1}{2}$ oz. and claims more than 50 per cent. cures. Hetol or Sodium Cinnamate is also extensively employed, and Landerer in his most recent reports recommends intravenous injections of this salt commencing with $\frac{1}{2}$ grain, increased gradually to 15 times this amount, and he claims "cures" to the extent of 85 per cent. Tyron advocates Iodol used as an inunction (20 grs. to 1 oz. Oil of Oil), 1 dr. gradually increased to $\frac{1}{2}$ oz. daily, and he maintains that great improvement always results. Euphen and Iodoform have been recommended upon the same principles.

Great activity has been shown of late years in the treatment of pulmonary phthisis by methods which are intended to bring the antiseptic or antiparasitic agents into direct contact with the diseased spots with their contained bacilli. Inhalations, sprays, insufflations, and parenchymatous injections have been tried, but taking all the reports into consideration, though marked temporary improvements have been often recorded, the general results have been disappointing. A few of the more important methods will be briefly summarised.

Murrell from laboratory experiments was led to try the inhalation of 6 per cent. Formaldehyde solution, and he believes it to be an agent of great value. Compressed air being made to bubble through the solution, the patient inhales this twice a day or breathes the vapour of the solution sprinkled on a bib placed under the chin. Green uses the following solution for the inhaler—Formalin, 1 dr., Glycerin, $4\frac{1}{2}$ drs., water, 5 oz.

Hydrofluoric Acid has been much used, and some good results have been reported, but most authorities have denied that it has

had any beneficial effects, so that it is needless to describe the method which is carried out.

Carasso has published a record of 43 cases of advanced phthisis, 37 of which were cured by the method of (1) continuous inhalations of *Ol. Ment. Pip.*; (2) the administration of the Oil with Creosote by the mouth, and (3) systematic over-feeding. The bacilli disappeared in from 10 to 60 days, and large cavities rapidly healed up.

The perforated zinc inhaler, used with persevering care in conjunction with the internal and external or "intensive" method of administering Creosote, has given decidedly beneficial results, but how much of the good is owing to the other means of getting the drug into the system it is hard to say. Where the fœtor of the expectoration is marked there cannot be a doubt that this treatment is most beneficial. A few drops (15 minims) of a solution of Creosote in Alcohol (1 in 3 or 4) may be sprinkled upon the sponge several times during the day.

Thymol, Guaiacol, Iodine, Carbolic Acid, Eucalyptus, Iodoform, Oil of Peppermint, Monochlorophenol, Eucalyptol, Chlorine, Menthol, and various other volatile antiseptics have been used in this way with varying successes.

Coghill's Inhaler Liquid consists of—*Creosoti Purif.* 3j; *Acidi Carbolici 3ii*, *Tinct. Iodi Æther.* 3ii, *Spt. Vini Rect.* 3iii. misc.

Iodide of Mercury—1 part of Iodide of Mercury and 1 part Iodide of Potassium in 5,000 to 15,000 water—to be used as a spray, has been extolled as a bacillus exterminator. It has been used in solution of 5 to 10 times this strength. Yeo recommends a spray of Benzoate of Soda 5 to 10 per cent.

It is, however, doubtful if any of the above solutions reach the bacilli in the lung tissue, but a portion of the dose finds its way into the circulation eventually, and may do good. The new plan of dividing the spray so finely by the Nebulizer or Atomiser is now much practised.

Recently excellent results have been published from inhalations of Nascent Ammonium Chloride; the ordinary inhaler for this purpose is useless. The patient is kept night and day in a room in which chloride of sodium is sprinkled upon dishes containing strong sulphuric acid placed alongside vessels containing strong ammonia. The room soon becomes filled with the Nascent Ammonium Chloride, which the patient continues to breathe for long periods.

Compressed air is recommended by Forlanini, and Oxygen and Ozone have been tried, and even Nitrogen, diluted with twice as much air, has been administered by Valenzuela, who finds the effects the same as if rarefied air was used, a marked antipyretic action being always observable. Murphy advocates the injection of sterilised Nitrogen into the pleural cavity with the view of causing collapse of the affected lung, and so putting it into a condition of rest, whilst other observers insist upon the value of

pulmonary gymnastics with the view of causing deeper breathing. German See has conducted extensive experiments upon the treatment of phthisis by artificial or medicated atmospheres under pressure, and he reports improvement of appetite, gain of weight, diminution of cough and expectoration, and subsidence of fever. His method is carried out by placing the patient in a close chamber for one, two, or three hours, into which air was forced at an increased pressure of about half an atmosphere, after passing through a solution of Creosote and Eucalyptol.

Parenchymatous or Intra-pulmonary injections have been tried in a great number of cases during the past few years, and sometimes with partial success and sometimes with evil results. These are being now abandoned.

The method of injecting various antiseptic solutions into the trachea by means of a syringe, whose curved canula is passed between the vocal cords, has found favour with many. Great relief to cough and improvement in most of the symptoms have been reported after the injection of 2 drs. of 10 per cent. Menthol and 2 per cent. Creosote in Olive Oil. Mundell injects essential oils of Thyme, Cinnamon, and Eucalyptus, 1 of each in 24 parts sterilised Olive Oil.

Little need be said of the various suggested surgical procedures, as the tapping, washing out and draining of pulmonary cavities or the opening freely into them by bold and free incisions from without, with the view of applying the cautery or caustics. Such practice must show very different results from those published before interference of this kind comes to be recognised as a justifiable routine treatment in phthisis. The surgical treatment of large superficial basilar cavities is a legitimate undertaking in many cases.

Tuffier, having satisfied himself that the ordinary surgical procedures limited to the opening and drainage of large tubercular cavities did not exhaust the resources of the operator, was tempted to try resection of the lung in incipient phthisis, and he reports success in which he excised a portion of the lung containing a nodule of tubercle.

Koch's method of treating pulmonary phthisis has been almost abandoned. The writer believes that injections of minute doses of Tuberculin may yet be found to afford the best results in the treatment of phthisis. Reports still are being published showing results from Koch's new and improved tuberculin. Klebs' method by the injection of the zymases of tubercle bacillus cultures, Tuberculoidin and Antiphthisin, though he claims improvement in 78 per cent. of the cases, must still be regarded as experimental.

Cantharidinate of Potash, the injection of Dog's Serum and Goat's Blood were mentioned in detail in a former edition of this work, but they have not stood the test of time.

Following the success obtained by the injection of the serum of immunised animals in diphtheria, Viquet has tried successfully

injections of ass's serum in phthisis. Maragghano has prepared a serum from dogs, horses, and asses, immunised by tubercular toxins, and he has reported most encouraging results in a large number of cases. His method promises well, but has met with little success in the hands of others. Bier has recently advocated transfusion of defibrinated Lamb's Blood, and he publishes a list of successes.

Richet has drawn attention to the value of Raw Meat, which he believes has a different action from over-feeding, as it possesses immunising powers analogous to the serums. To this treatment he gives the name of Zomotherapy.

Remedial agents for the treatment or relief of some of the more prominent symptoms of phthisis may be mentioned. Cough demands attention in most cases at some stage or other of the affection but there can scarcely be instanced a greater mistake in medical practice than the routine treatment of pulmonary consumption by cough mixtures. The use of the various expectorants and anodynes which unfortunately constitute the chief portion of the antiphthisical armamentarium of some physicians only leads to destruction of appetite, injury of digestion, increase of sweating, and all the numerous ills resulting from retained secretion.

In the early stages of phthisis where the incessant, hard, dry, hacking cough interferes with the patient's rest and assists in keeping up the irritation and fever, it is the duty of the physician to administer anodynes in small and oft-repeated doses so as to slightly influence the respiratory centre and check coughing, which is as injurious as it is useless. The Saline mixture mentioned upon page 730 will be found to meet the case, and the quantity of Morphia Solution may be doubled, and a few drops of Dilute Hydrocyanic Acid may be substituted for the laurel water in each dose. Mixtures of this sort should be given very sparingly through the day, but they may be administered more freely during the night. The citrate of potassium formed on adding the lemon juice to the alkali is a valuable expectorant, and where the mucus is tenacious in cases characterised by difficult expectoration, Ammonium Carbonate to about half the amount of the potassium salt may be substituted. Heroin ($\frac{1}{16}$ gr.) is recently extolled as a safe sedative for the cough of phthisis.

A tea-spoonful of Sal Volatile in a wine-glassful of water, to which a table-spoonful of fresh Lemon Juice and 5 minims of Morphia Solution have been added, is always a perfectly safe combination, and in the dyspnoea of the cavernous stage it may be given to great advantage if the morphia be omitted.

Iodide of Potassium with small doses of Specacuanha Wine may be tried after meals.

The various remedies already mentioned as valuable in the constitutional treatment of the disease will be found of great benefit to the cough. Thus, Cod Liver Oil often relieves it, and *Creosote* is frequently very efficacious at all stages of the affection.

Tar and Creolin act in the same way. Counter-irritation by small blisters, or Iodine, or Chilli Paste often helps the cough.

The various inhalations already mentioned may be tried. Indeed, as a rule, everything or every method should be preferred which will give relief to cough without drugging by Morphia, Chloral, Henbane, Hemlock, Bromides, &c.

Creosote inhalation, as already mentioned, is indicated, especially in basilar cavities, or where expectoration is profuse and fetid.

The Pinus Pumilio is a grateful and efficacious remedy.

Conium and Hydrocyanic Acid often act speedily in subduing spasmodic cough when administered in the form of an inhalation.

When the cough is accompanied by pain, or where from pleuritis or pleurodynia each deep inspiration is painful, Anodyne liniments, as Chloroform and Belladonna, may be applied under oiled silk or upon spongio-piline. There is nothing gives such relief as strapping the affected side of the thorax by long strips of the adhesive plaster, passed from the sternal region of the sound side round the pained ribs, and catching firmly upon the opposite side of the vertebral column, so as to immovably fix the affected pleura as in a vice, after the method suggested by Roberts.

Poulticing, as a rule, is of little use in such cases, but in local inflammatory complications of superficial extent, it may be often utilized with great advantage for short periods. Blistering and counter-irritation by Iodine, &c., often gives great relief.

Fever or pyrexia is one of the most serious symptoms which the physician will be called upon to contend with in the course of phthisis. Up till comparatively recently he had to content himself with looking on while the patient slowly or quickly burned himself out. Too often the suffering of the phthisical victim will be found to be measured by his increased temperature, and if this can be reduced and kept within bounds by safe measures, much of the pain, distress, and indescribable weariness which characterize some examples of the disease may be obviated. Quinine is unreliable, and in doses of large amount often aggravates the patient's discomfort by the unpleasant symptoms of cinchonism, or by the still more undesirable effect of drying up his expectoration and increasing his cough. Yeo points out the antipyretic value of small doses, and gives it in the following:—Hydrochlorate of Quinine 2 grs., Hypophosphite of Lime 4 grs., Tincture of Nux Vomica 15 mins., Tincture of Orange 30 mins., Glycerin 1 dr., and Water to 1 oz., to be taken half an hour before meals.

Digitalis has been recommended alone or in combination with quinine. Niemeyer's pill, consisting of Digitalis gr. $\frac{1}{2}$, Quinine gr. i., and Opium gr. $\frac{1}{2}$, is a favourite combination.

Antipyrine and Antifebrin are of great value in the treatment of the pyrexia of some cases of phthisis. The original large doses are now abandoned, and 5 grs. repeated for 2 or 3 times at short intervals generally suffice to give relief.

It is needless to discuss the advantages of these remedies.

Though they in no way tend to affect the ultimate end to which the diseased action is slowly or quickly progressing, anyone who watches the ease and comfort so frequently following their administration will not withhold them in every case of phthisis. The drawback most likely to cause inconvenience will be excessive perspiration, and in very advanced stages of the disease, in very weak patients, they should be given cautiously, and in very small doses. $3\frac{1}{2}$ grains of antifebrin often give relief under such circumstances. Since using antipyrine, the writer has seldom had to employ sponging or to give wet packs for the high temperatures of acute or chronic tuberculosis.

These new agents, it must be remembered, are not suitable remedies to be used in a *purely routine* manner in the treatment of every rise of temperature in chronic phthisis. Williams does not speak highly of them, and when an agent for the relief of high temperature is needed, he prefers Quinine and Salicylates. For the pyrexia of the first stages of tuberculosis, he prefers derivative measures, such as counter-irritation and salines.

Where the temperature, however, rises to a height bordering upon hyperpyrexia, in the opinion of the writer, these agents are of little value, and cold or tepid sponging must be relied upon. Renzi recommends large doses, 15 grs., of Thymol, increased till 90 or 100 grs. be taken in the day.

Hæmoptysis occurring during the course of phthisis will be met by remedies mentioned upon pages 356—359.

Diarrhoea.—Under this heading, upon page 212, the various remedial measures useful in the treatment of different kinds of diarrhoea have been enumerated.

There is no special or specific astringent for phthisical diarrhoea. Where ulceration of the intestines exists, Opium or Morphia is indicated, in doses sufficient to quiet peristalsis and relieve pain, and occasionally Lead or Copper Salts may be also indicated, but where a pure astringent action is desired in the chronic diarrhoea of phthisis, the writer avoids the metallic astringents, and selects Hæmatoxylon as the least objectionable and most efficacious remedy of this class. It may be given in pill, powder, or mixture, 10 to 15 grains of the dry powdered extract being a moderate dose. Every known astringent and antiseptic remedy has been tried and generally found of some use. Tannoform is invaluable.

Beta-Naphthol, Hydro-Naphthol, and small doses of Hydrarg. Perchlor. are advocated.

One Creosote capsule after each motion sometimes acts like a charm.

Lactic Acid has recently been found of the greatest service by some observers, and Talc is used by others. (See under Diarrhoea, page 209.)

Under Peritonitis are detailed the extraordinary results of treating abdominal tuberculosis by laparotomy.

Night Sweating.—The old-fashioned pill is still regarded as

one of the best remedies. It may be given at bed-time, or oftener if required.

R. *Zinci Oxidi* gr. iijss
 Ext. Belladonnae gr. ʒ.
 Ext. Hyoscyami gr. iijss *misce*

Fiat pilula. Mille tales xxiv Sumat unam hora somni.

Belladonna or Atropine seldom fails to relieve the sweating to the dryness of the throat and the effects upon the expectoration and the heart often prevent its being used in such doses as give reliable results. One minim of the official Solution of Atropine representing $\frac{1}{160}$ grain, very generally checks sweating in places, or 15 minims of the tincture may be given in the evening and 5 minims every two, three, or four hours afterwards, may be safely administered. Occasionally belladonna and atropine fail.

Agaricine possesses very marked influence in checking the night sweats of phthisis, as first pointed out by Murrell. No disadvantages follow its action, and in some cases it affords relief where every other drug fails. $\frac{1}{4}$ grain of the white crystalline powder may be given every four hours in very severe cases. Often one dose acts like magic, and repetition may not be needed for a considerable time. It may be given alone, in Aromatic Sulphuric Acid, or with Dover's Powder.

Camphoric Acid has been recently extolled when given before the expected perspiration, in doses of 20 to 30 grains.

Hyoscine in minute doses, $\frac{1}{160}$ grain hypodermically, gives good results.

Dover's Powder in 1 grain doses is used by some, but it is very uncertain.

Picrotoxin, $\frac{1}{160}$ grain, often acts most beneficially, and Strychnine often succeeds.

Quinine in 3 to 6 grain doses may be tried, and Arsenic in small repeated doses occasionally answers well, or a combination of Quinine, Arsenic, and Digitalis may be tried.

Mescaline, $\frac{1}{4}$ grain, hypodermically, checks phthisical sweating, and it may be also given by the mouth, but it often fails.

Sulphonal, in addition to its hypnotic properties, may be very often found to give excellent results in this complication. The writer has used it with benefit in doses of 6 to 8 grains.

Chloralose also induces sleep, and checks the sweats at the same time. It may be given in 10 gr. doses. Chloralamide acts in the same way in doses of 30 grs.

Phosphate of Calcium in 8 to 12 grain doses has sometimes given good results, as it may check both sweating and diarrhoea and Yeo recommends the Hypophosphites as the best preventives for excessive perspiration.

Tannic and Gallic Acids, Sulphuric Acid, Sulphate of Iron, Ergot, Alum, and many other drugs have sometimes proved useful.

Tellurate of Sodium, in doses of $\frac{1}{4}$ grain in pill once a day, has given excellent results, but the most objectionable garlic odour given to the breath is a barrier to its use.

Acetate of Thallium in 1 to 2 gr. doses is highly recommended by Combermale.

Recently Tannoform has given satisfactory results when freely dusted over the skin with a pad of cotton wool.

Sponging the body over with vinegar or vinegar and water generally affords some relief, and Belladonna may be used in the same way with advantage. Chloral, 2 drachms dissolved in a tumblerful of brandy and water, has been found very useful when sponged over the body. Very hot water often acts promptly when used in the same way, as does Solution of Alum.

Rosenbach reports encouraging success after the application of an Ice-bag over the abdomen, for several hours during the night, in cases where other remedies fail.

Laryngeal symptoms are to be met by the remedies mentioned upon page 503 for laryngeal phthisis.

Peritoneal complications are referred to under the treatment of Tubercular Peritonitis, on page 694.

Pneumothorax and renal complications are to be found under their respective headings.

The *Preventive* treatment of phthisis is one of the most important subjects in the entire range of medicine, and never in the history of the world has a deeper and more widespread public interest been aroused in any medical question. The recent Tuberculosis Congress which met in London has given to the public the views of the leading authorities upon the dangers of infection from the dissemination of the bacilli from the spata of physical patients. Koch's statement that bovine tuberculosis was not communicable to man caused a profound sensation. It is needless to say that in this country his conclusions are at present almost universally rejected by the profession, and until proof is forthcoming it is the serious duty of every physician to impress upon the lay public the necessity of the most rigid attention to the purity of milk and the soundness of the meat supply. Such questions as Notification, Isolation, and Free Sanatoria, are obviously beyond the scope of the present volume. The writer from close clinical observation, has long since satisfied himself that one of the main elements in the propagation of tubercle is the milk supplied by cows suffering from tubercular disease of their mammary glands, and he does not believe that there are many clinical facts more obvious than the relation of tubercular milk and food to the origin of the tubercular glands so common about the jaws and necks of those suffering from necrosing teeth and diseased tonsils. Hence, he regards the sanitary condition of the mouth and pharynx as a matter of the

most vital importance, and only second to the sterilisation of milk, and probably more important than the measures for the destruction of sputum.

PITYRIASIS RUBRA, or EXFOLIATIVE DERMATITIS.

The treatment of this very formidable affection is not so hopeless as Hebra's opinion would lead one to expect, the writer in a limited experience having seen at least four cases, closely agreeing with Hebra's description of the disease, which completely recovered under appropriate treatment. Internal remedies do not appear to exercise much influence, and in the successful cases it is very doubtful if they have contributed much to the result. After trying most of the reputed remedial agents, the writer is inclined to believe that if any good is to be obtained from drugs internally it will be furnished by small doses of Arsenic in combination with a diaphoretic and diuretic.

In the early stages of the disease arsenic should not be given, but Tartarised Antimony should be used in its stead.

Cod Liver Oil and Iron at a later stage are also probably useful.

Local treatment will undoubtedly do much if conscientiously and patiently carried out, the chief indication being to protect the affected part (the entire cutaneous covering of the body) from the irritation produced by contact with the air and variations in temperature. Where the disease is secondary to some other cutaneous affection, the primary lesion must receive the first attention. Special symptoms will call for endless modifications of details. A weak Alkaline bath, containing Bran, Starch or a little Carbolic Acid, may be permitted for one or two hours daily where itching is very troublesome. S. Mackenzie recommends the following baths.—Starch, 1 lb., or bran, 2-6 lbs., or linseed, 1 lb. or gelatin, 3 lbs., or gluten (size), 6 lbs., to 30 gallons of water or 3 oz borax, or 8 oz. bicarbonate of soda, to the same amount of water. Most reliance is to be placed inunctions by an animal or vegetable fat. These should be carried out several times daily by an experienced hospital nurse told off for the purpose. Fresh Lard, deprived of every trace of saline matter, answers the purpose well. About 2 ounces of the simple Liniment of Camphor may be added to each pound of the fat and in summer Suet may also be added. This may be rubbed in gently and patiently, after the scales have been removed by prolonged immersion in the warm bath, or by very gentle friction with a soft rough cotton towel. Zinc Ointment, to which 10 per cent. of Liq. Carb. Detergens and the same amount of Camphorated Oil have been added, is to be then smeared over the limbs, which should be covered with lint or old linen also well coated over with the ointment, and comfortably bandaged, the body being several times anointed with the lard during the day, whilst the limbs and face need be only dressed morning and night with the ointment. Mackenzie prefers watery applications, and he puts the patient

into clothes made of lint, and keeps them saturated day and night with a lotion consisting of 8 oz. Glycerin of Subacetate of Lead, 8 oz. pure Glycerin, and water to 1 gallon. Cod Liver Oil and Olive or Almond Oils may be also used. Some cases have been successfully treated by causing the patient to live in a warm bath for many days or even weeks at a time.

PITYRIASIS VERSICOLOR, or TINEA VERSICOLOR.

Being a harmless parasitic affection, only slightly if at all contagious, its treatment is seldom demanded by the patient, who, as a rule, is scarcely conscious of its existence.

Almost any antiparasitic remedy speedily removes the discoloration, and the physician can use any antiseptic solution which pleases his fancy. The most elegant will be.—

R. *Hydrarg. Perchloridi* gr. xv.
 Ammonii Chloridi gr. xv.
 Spiritus Lavandulae ℥vi.
 Mistura Amygdalæ ad ℥x. misce.

Fiat solutio. Signa—"To be freely sponged over the discoloured spots every night."

Carbolic Lotion or a strong Carbolic Soap will remove it. In phthirical patients the affection is common, and is sometimes entirely removed by the application of Iodine which is used for purposes of counter-irritation, or by Eucalyptus or Creosote Ointments applied with other objects in view.

Sulphurous Acid Solution (1 in 5), or Sulphites, or Sulphides, are speedy and cleanly.

PLACENTA PRÆVIA.

Though a description of the various operative measures which may be demanded at the puerperal period is outside the scope of the present volume, a brief reference to the treatment of this formidable abnormal condition may be here inserted for reference in emergency.

The management of the case will depend, to a very large extent, upon the term of the pregnancy, duration, and extent of hæmorrhage, &c.

In the earlier months (before the seventh) where the hæmorrhage calls attention to the condition and the diagnosis is clear, the treatment of the case will be pretty much like that of an abortion. Absolute rest upon a hard bed in a cool room, with the usual precautions indicated under Abortion, may tide the patient over the period when the viability of the child may be naturally expected. This expectant plan is, however, only justifiable when

the hæmorrhage is very small and the onset of severe bleeding which may demand immediate action, is always to be arranged for.

The following rules are laid down by Braxton Hicks for the management of placenta prævia :—

1. After diagnosis of placenta prævia is made, proceed as early as possible to terminate pregnancy.
2. When once we have commenced to act we are to remain by our patient.
3. If the os be fully expanded and the placenta marginal, we rupture the membranes and wait to see if the head is soon pushed by the pains into the os.
4. If there be any slowness or hesitation in this respect then employ forceps or version.
5. If the os be small and placenta more or less over it, the placenta is to be carefully detached from around the os. If no further bleeding occur we may elect to wait an hour or two but should the os not expand and if dilating bags are at hand, the os may be dilated. If it appears the forceps can be admitted easily they may be used but if not version by combined external and internal method should be employed, and the os plugged by the leg or breech of the *fœtus*, after this is done the case may be left to nature with gentle assistance, as in footling and breech cases.
6. If the os be small, and if we have neither forceps nor dilating bags, then combined version should be resorted to, leaving the rest to nature gently assisted.
7. If during any of the above manoeuvres severe bleeding should come on, it is best to turn by the combined method in order to plug with the breech.
8. Where the hæmorrhage occurs before the end of the seventh month, version by the combined method, no force following is the best plan.

To these I may add however if we employ a routine method in all cases, it will be found that the version by combined method no force following, gives a result as good if not better than any. The after-treatment must be conducted on modern principles. Should oozing occur after the expulsion of the placenta the swabbing of the lower uterus by styptics will be easy and inasmuch as the outlet of the uterus is liable more especially to be blocked by adherent clots it will be wise to irrigate the cavity daily with some antiseptic solution, or to insert iodine pessaries into the vagina, particularly if the irrigation cannot be done.

Where there are indications for the introduction of dilators Champetier de Ribes's bag answers perfectly. Most operators have found this appliance to suit admirably in placenta prævia it dilates the os, checks hæmorrhage and brings on labour.

Smiley, in his recent Ingleby Lecture, thus sums up the management of this serious condition :—

"The modern treatment is simple and effective and eliminates almost all the risks. It consists in rupturing the membranes as early as possible and bringing down a foot at the earliest possible moment, the body of the child pressing on the placenta acts as an efficient and aseptic

plug, and the membranes being ruptured no further separation takes place. The great advantages of this method are that it completely arrests the hæmorrhage, that it involves but slight manual interference, and that such manipulations as are necessary are conducted within the membranes, that the child is not extracted, but its expulsion is left to nature so that the cervix is not torn, the uterus remains firmly retracted and the placental vessels securely thrombosed.

"In carrying out the procedure the patient should be placed upon her back, since the lateral position usually adopted in this country favours the entrance of air into the veins. If the lower extremity does not present, the child must, of course, be turned, and preferably by external manipulation, but, failing this, by Braxton Hicks's method of bipolar version. The vagina should be rendered as aseptic as possible before the introduction of the hand, but no poisonous antiseptic, such as corrosive sublimate or carbolic acid, should be used, since the close proximity of open blood vessels renders their use peculiarly dangerous. Very rarely is traction on the foot required, and then only sufficient to control hæmorrhage. In no case should the child be extracted.

"The comparative merits of the different methods of treatment which I have mentioned are no longer open to discussion, but are established by ample statistical proofs, and a definite mortality attends the employment of each. In a recent communication Dr. Strassmann says that the mortality in the Charité Hospital, Berlin, in cases of placenta prævia treated by version by abdominal manipulation, bringing down a foot, and leaving the expulsion of the child to nature, was only 1.45 per cent. Where the same method was adopted, but with bipolar version, 8.6 per cent., and where version was followed by extraction, 20 per cent.

"There are two conditions in which the treatment which I have advocated is not advisable—first, where the head has passed the os and can be more safely delivered by forceps; and, secondly, where the os is not sufficiently dilated to admit two fingers. In such cases I should advise the plug, but they must be exceedingly rare, for I have never met with one myself, and Doctor Strassmann says that in the Charité the plug was never required."

Donoghue recommends Cæsarean section in all cases of complete prævia, in cases in primiparæ where maternal exhaustion is evident, where there is a rigid os, transverse position, or a history of previous operative delivery.

PLAGUE—Bubonic Plague.

The preventive treatment of this disease is a question of world-wide interest, and its literature is daily increasing. The spread of the disease from soil, impregnated with the bacillus of the disease, is established, and though it is not likely with the greatly improved sanitary conditions of large cities that the disease can ever assume the grave virulence which it exhibited in the fourteenth century

when one-fourth part of the population of Europe was wiped out by it, nevertheless, its prophylaxis is of vast importance. It is unnecessary to enter into questions of quarantine, especially since the Local Government Board has taken all regulations of isolation as regards communities into its own hands.

Personal cleanliness, thorough ventilation, rigid isolation of all suspected cases, and their instant removal to hospital upon the signs of the disease, the most thorough disinfection of homes and the destruction of excreta, clothing, &c., must be insisted upon. Methods for the extermination of vermin are of importance, since it has been clearly demonstrated that rats play a prominent part in its dissemination, and house flies and even fleas may act as carriers of the virus from the dead to the living. (It seems, for example, highly probable that rats infect each other through ear fleas which infest them.)

In the mild cases of *Pestis minor*, where there is little constitutional disturbance, and the disease can only be suspected from the presence of the glandular enlargements, little is necessary to be done as these cases always recover; they are often overlooked and it is certain that their appearance may precede the advent of the *Pestis major* by some months, or they may rapidly pass into the grave form—the typical bubonic plague.

All ordinary remedies, as Quinine, Perchloride of Mercury, and nearly every known antiseptic has been tried and found useless. Owing to the rapidity of the disease towards a fatal issue the ordinary routine treatment useful in the severe fevers is also useless, and even alcoholic stimulants, cardiac tonics, antiseptics, &c., are of no avail. The buboes may receive local treatment in the form of antiseptic poultices, and at a later stage, if the patient survive, they should be incised and thoroughly drained, and in some cases excised or curetted. The injection of strong disinfectants into the swollen glands has led to no practical result. The pneumonia often present is little influenced by drug treatment.

The only hope in treatment lies in Serumtherapy. It cannot be denied, however, that the good results obtained by Yersin have not been maintained, and at present the outlook of the serum treatment is far from satisfactory.

Yersin's first serum which inspired confidence in the therapy of plague was prepared by injecting the horse with living cultures of very potent bacilli of plague, and his serum was demonstrated to be both prophylactic and curative as in the case of the antitoxin of diphtheria. Later on the remedy was prepared by injecting dead or sterile cultures, and the results were very unsatisfactory, many observers denying any curative virtue of the serum, but by modifying the routine and injecting into the horse dead cultures, soon afterwards followed by the injection of living virulent cultures, a serum is now obtainable from the Pasteur Institute which promises to give most satisfactory results. The dose of 20 c.c. injected directly into a vein and 50 c.c. subcutaneously is

two doses afterwards, all within 24 hours, to be followed by a daily dose of 20 c.c. or more till the fever disappeared, have given excellent results. Simpson gives this as the explanation of the first successes in China, the comparative break-down of the treatment in Bombay, and the recent success in Oporto.

Haifkine's Prophylactic is a pure culture of the plague bacillus, sterilised by a temperature of 65° C. The dead bacilli and their chemical poison are both contained in this liquid. The dose is 3 c.c., and he claims for it also curative virtues which have reduced the mortality by 50 per cent. Mallannat has been able to isolate in a pure condition the immunising substance contained in the serum.

The serum of Lustig consists of a solution of the Neucleo-proteid obtained from plague bacilli cultivated on solid media, and it is claimed to be more reliable and perfectly innocent, but its curative action is very doubtful.

PLEURITIS, Acute.

Acute inflammation of the pleura is to be met by the measures already pointed out as beneficial in the treatment of other inflammations. The most prominent symptom, and the one calling out most loudly for relief, is pain. This should be promptly met by Morphia or Opium, and these agents act beneficially in other ways than simply by giving relief to the patient's suffering. If the case is seen from the first onset of the disease, when the pain in respiration or in coughing is very severe, a hypodermic injection of $\frac{1}{2}$ grain of Morphia may be administered in the region of the pained pleura. This may not be repeated unless under exceptional circumstances, as the best effects of opium in the inflammation of serous membranes will be obtained by oft-repeated small doses by the mouth. With the opium should be combined remedies which will have some effect in subduing the fever, by acting upon the skin and quieting the circulation. Even at the very onset the writer has used the new antipyretics with great benefit where the constitutional disturbance and fever heat chanced to be very high. This, however, is not frequently the case, and the best routine treatment at this stage will be found in a simple diaphoretic combined with an anodyne, as in the following:—

- R. *Liquor. Morphue Hydrochlor.* ℥℥xxx.
 Tinctura Aconiti ℥xxx.
 Liquor. Ammon. Acet. ℥iiss.
 Vini Antimonialis ℥iiss.
 Aquæ Camphoræ ad ℥viiij. *misce.*

Fiat mistura. Capiat cochlearium magnum tertia quaque

The exhibition of opium is not the only measure to be relied upon for the relief of pain.

General blood-letting is unfortunately now seldom used. In severe cases it may save life, and any one who, like the writer has seen it afford marked and speedy relief with amelioration of every symptom will not readily be seduced into the present prevailing belief in its inefficacy. When the urgency of the pain and dyspnea warrant the letting out of blood, a large opening should be made in a fair-sized vein, 12 ounces, or even a pint of blood, may be allowed to freely flow, and instant relief may follow.

Leeching, though acknowledged to be less efficacious, is much more frequently practised. Ten leeches may be placed over the affected side, and if the patient has sufficient adipose covering over his ribs there cannot be a doubt about the advisability of putting one or two cupping glasses over the bites and extracting free blood. In thin patients this can be accomplished by hot fomentations. The action of the leeching may be intensified by the administration of a large Saline purgative. The writer is by no means satisfied that leeching is of much use, save for the relief of pain, and given a case where the extraction of blood is considered to be necessary by the urgency of the dyspnea and other distress he thinks that it will be safer to open a vein. The application of the cupping glass alone, or after leeching, is undoubtedly a very efficient method of relieving pain.

Poulticing is the old-fashioned and still popular method of relieving the pain of acute pleuritis, and hot linseed cataplasms applied frequently afford the safest and least objectionable routine plan of treating mild cases of the disease where blood-letting and leeching are contra indicated. Hot fomentations, with or without Turpentine, act in the same way. The first poultice may contain half its weight of mustard, and the subsequent ones may be entirely of linseed meal, or the ingenious plan mentioned *op. cit.* page 690 may be adopted. Poulticing may be advantageously stopped as soon as pain subsides. Cold applications, compresses, Leiter's Tubes, or Ice-bags have been suggested and used instead of poulticing or hot fomentation. There is not sufficient evidence of the value of this practice to justify one in recommending it as a routine, but enough proof of its occasional usefulness has been demonstrated to warrant one in readily adopting it when warm or hot applications fail to afford relief.

Blistering the chest for the relief of pain in the early stages of acute pleuritis has still many advocates. Fagge maintained that it appeared to him more serviceable than any other measure, it is often undoubtedly of much service during all the stages of the disease from its onset till the absorption of the last remnants of effused fluid.

The blistering unfortunately interferes with the next remedial measure for the relief of pain, though leeching and poulticing do not do so necessarily.

Strapping the affected side may be accomplished by means of strips of Mead's adhesive plaster, starting from the front of the chest on the sound side of the sternum, and ending upon the sound side beyond the spine, after enveloping the pained side firmly as in a vice, whilst the patient expires as forcibly as possible. This prevents the use of the affected lung and pleura to a great extent, and not only is pain relieved at once but the rest is most beneficial as in the treatment of every other inflammation, and this method often appears to cut short the duration of the attack and the amount of effusion. A bandage 3 or 4 inches wide may also be used to relieve pain when applied tightly round the chest. This is known as Otto's method, and it is often valuable.

The hypodermic injection of Cocaine ($\frac{1}{2}$ to 1 grain) over the seat of the pain has given relief. As a rule, in acute pleuritis, little satisfaction may be expected from anodyne liniments as Belladonna, Chloroform, &c.

During the time that these local remedies are being exhibited the morphia mixture, with the aconite and antimonial wine, should be continued till the absence of pain and the subsidence of the fever call for its discontinuance.

Some physicians regard pleurisy as a manifestation of rheumatism, and treat it from the first by pure Salicylic Acid, others independent of the rheumatic hypothesis affirm that the pure acid gives the best of all results, and it cannot be denied that it is very often most satisfactory. 15 grs. in water paper may be given at first every 4, and then every 6, and afterwards every 8 hours with great advantage, or the Soda Salt may be administered.

Up to this time the patient should be maintained in a position of absolute rest in bed, and this must be continued till the daily physical exploration of the chest proves that the effusion has ceased to increase, or as long as the amount of fluid remains considerable.

Diet is to be of the simplest, solid food being prohibited, milk and farinaceous foods being the chief part of the diet.

Purgatives are not called for, except at the earliest and during the later stages, and alcoholic stimulants are seldom indicated till the disease passes into a chronic form. As the effusion increases there seems to be some chance that by diminishing the amount of liquids consumed the effusion may be held in check. If this is true it must only be to a very limited extent, though the so-called "Dry" treatment of pleurisy has found many advocates.

For all practical purposes the question now becomes one of the treatment of the *result* of the pleuritis, or, in other words, of the treatment of effusion within the pleura. The first point for settlement is whether the case is one for surgical or medical treatment. If the effusion is moderate in amount, and does not by its quantity threaten seriously to embarrass the heart and to impede respiration, there can be no doubt that the physician is justified in waiting to see if the absorption will commence. Remedies of considerable

power in hastening this should now be tried. Locally and constitutionally the effusion may be attacked.

Blistering is often very successful, and one large cantharidine plaster may be applied to the centre of the affected side of the thorax, where it may be permitted to remain for eight or ten hours till thorough vesication results. As a rule, the plan of applying several small blisters for three or four hours each to different parts of the chest gives better results. These flying blisters may be made about 3 inches long and $2\frac{1}{2}$ inches broad, and may be placed upon different parts of the chest wall at the same time. The simplest way, however, is to use one blister, which should be kept on for, say, two hours near to the lower margin of the diaphragm. It may then be placed six inches higher up, and allowed to remain in contact with the skin for three or four hours, after which time it may be applied somewhere near to the level of the upper limit of the effusion for six or eight hours.

Sometimes the effect of this treatment is quite striking and occasionally rapid diminution in the amount of fluid may be dated from the time of trying the blisters. It is generally useless if, whilst the amount of fluid is steadily increasing, the writer has long been convinced that the marked benefits observed after blistering by cantharides cannot be explained entirely upon the counter-irritation theory; he believes the absorbed cantharidine has some specific effect upon the lymphatics or a lethal action upon the microbes which are always present.

Iodine Liniment as a counter-irritant, or equal parts of the Tincture of Iodine and Glycerin painted on with a view of being absorbed, may be tried. Every known counter-irritant has been used, and occasionally with success. The iodine is, perhaps, the best of the class after cantharides. Prozorovsky adds 25 per cent. Guaiacal to the tincture of iodine and covers it over with fine silk.

Mercurial Ointment (1 in 6 or 8) may be freely rubbed into the chest wall, taking care that salivation does not follow from its long protracted use of the remedy. If any improvement is to be got from its application, signs should show themselves during the first two or three days after its being used. The Oleate of Mercury may be used or excellent results may be obtained from applying a dilute mercurial ointment, or oleate of mercury ointment upon lint, and applying strapping over this as in Roberts' plan. In this way the Liniment of Iodide of Potassium and Soap may be used sometimes to great advantage.

Internal remedies consist of absorbents like Iodides, diuretic-like Caffeine and Digitalis, purgatives of the Saline class as Sulphate of Magnesia, and diaphoretics like large doses of Jaborandi or Pilocarpine ($\frac{1}{4}$ gr. hypodermically).

Some of these agents can be tried together. Thus, the following is a combination of value.—

- R. *Tincturæ Digitalis* ℥iv.
Tincturæ Scilla ℥iii.
Potassii Iodidi ℥ii.
Decocti Scoparii ad ℥x. *misce.*

℞. mist. Capiat ℥ss. quater in die post cibos ex ℥i. aqua.

The diet may now be changed to one in which a small amount of fluid is allowed, meat, biscuit, stale bread, or old cheese being only permitted for the first three days, a tumblerful of fluid being swallowed on the third day. Some authorities speak highly of a liberal diet of milk—five or six pints daily. All the above internal measures may be tried; but, as a rule, they are uncertain and disappointing, and should not be too long administered. The best results are obtained from giving Salines according to Hay's method (see 7th Edition of the Author's work on "Materia Medica and Therapeutics," page 415.) After fasting, 1 oz. of Sulphate of Magnesia dissolved in the smallest quantity of hot water may be administered the first thing in the morning. Half this dose may be ordered twice a day for weak patients, and twice this amount may be given to strong plethoric ones.

Salicylate of Sodium in full doses (30 grains), and Salol (30 grains), four times daily are said to have a specific action over the effusion, and glowing accounts of the remarkable effects of Antipyrine in moderate doses (10 grains every four or six hours) have been published.

These measures, as already hinted at, are only warranted when the amount of fluid is not very extensive, nor are they to be used for any length of time, even when the amount of fluid is moderate, say 20 to 40 ounces. Delay in the removal of the fluid means great risk to the lung, which is less likely to ultimately expand in proportion to the length of time during which it has been compressed by the fluid. Hence, when several weeks have elapsed with a moderate quantity of effusion in the pleura, though there be little inconvenience and but slight displacement of organs, the fluid should be drawn off. Where the pleura is even filled only up to the angle of the scapula, and no symptoms whatever indicate to the patient that there is anything wrong, it is laid down that the fluid should be drawn off if it has resisted treatment for more than four weeks.

If the patient be found to have the whole of one pleural cavity full when first seen or to have both cavities half full, operation should not be delayed for the sake of trying the effects of drugs. Sudden death has been repeatedly noted when one cavity has been full, though no symptoms of pulmonary or cardiac distress were present to warn the physician of the impending catastrophe. Therefore, if in doubt, the best course is to decide upon immediate

tapping. Some authorities recommend tapping as early as the third or fourth day of the effusion.

Various rules have been formulated for the guidance of the physician as to when operation or waiting is to be decided upon. Some authorities are influenced much by the symptoms, the embarrassment of the breathing, others by the displacement of organs, others by the duration of the effusion, &c., but the one that generally underlies all these conclusions will be found to be that the simple operation of tapping is too often regarded as a last resource, only to be used when all other means fail.

The physician who decides upon purging, blistering, or diuretics in a case where dulness extends almost to the clavicle, will generally have his pains rewarded by the ultimate absorption of the effused fluid, but occasionally, though rarely, he may have the mortification of finding that his patient suddenly succumbs. More frequently will he experience that a tardy convalescence with a partially collapsed lung and shrunken chest wall will remain a monument of his patience and faith in drugs.

Procrastination often arises from some uncertainty in the diagnosis. This should never be. If the physician is in doubt the ordinary hypodermic syringe and needle will easily give him the required confidence. Already, the way that this instrument may be utilised for exploring purposes has been described. It should be thoroughly sterilised by immersion in some antiseptic liquid, and the cylinder being half filled with weak carbonic solution, the instrument is held vertically whilst the piston is screwed home by a few turns, so as to fill the needle with the solution down to its extreme point. It is then plunged into an intercostal space deeply, and if the pleuritic fluid does not flow into the cylinder upon screwing out the piston, a few drops of the solution may be injected so as to clear the needle of any plug of fibrin or coagulated blood, after which the reversal of the screw will draw up a fair sample of the liquid out of the pleura. It may be a tax upon the credulity of the reader to be told that after withdrawing a dozen minims of the effusion such a change is induced or set up in the pleura, and its contents, as sometimes leads to a speedy absorption of the remainder, yet the writer has observed this many times in hospital practice when the puncture has been made as a demonstration of physical diagnosis in old long-standing effusions. Such a result, however, is not to be counted upon where tapping is indicated in acute cases or where there is much liquid.

The hypodermic needle may be inserted anywhere, but, as a rule, it will be best to introduce it at a spot where tapping is to be performed, as then the physician will be more confident in the introduction of his trochar and canula. If fluid be present he will so certainly find it that there is little fear of a negative result embarrassing his future action, but cases have been reported where no fluid entered the syringe, though a larger instrument

was successfully employed immediately afterwards at the same spot. The writer is inclined to believe that this only occurs when an empty hypodermic syringe is employed. The spot to be selected for puncturing the pleura in paracentesis thoracis is not of very vital importance. Several situations have been recommended. The usual site is in the axillary line in the fourth interspace (*i.e.*, above the margin of the fifth rib) upon the right side, and in the fifth space (*i.e.*, above the margin of the sixth rib) upon the left side. Bowditch advises the puncture to be made between the ninth and eleventh ribs. It is advisable to keep close to the upper border of the rib, in order to avoid the intercostal artery, or to puncture far in the centre of the intercostal space. Other authorities, whilst keeping to the fourth and fifth spaces, select a spot in front of the axillary line, while some puncture at a short distance in front of the posterior fold of the axilla.

The most prominent or bulging space in any of these localities may be safely selected, and any spot should be avoided where there is reason to believe that the pleura is much thickened.

The pain of the puncture is avoided by the application of a little Ethyl Chloride spray or by freezing with Ether.

The best form of instrument has already been discussed and described when detailing the treatment of Empyema upon page 267, and there is no necessity for repeating the details here.

Upon the whole, the unequal suction force of the best aspirators is often a barrier to their usefulness in this operation, and where the syphon principle is not considered satisfactory in any case the writer employs Dieulafoy's aspirator; but after the fluid has commenced to run he does not exhaust the cylinder after emptying it each time, but slowly and patiently withdraws the piston and allows the fluid to flow in at a uniform and steady rate. The flow is too rapid when the piston is drawn up to the top of the cylinder and the stop-cock turned fully on.

In chronic cases with large effusions, as in malignant disease of the pleura, the writer has inserted a Southey's trochar and canula, and after withdrawing the trochar, a fine rubber tube being attached to the canula, the fluid is allowed to flow into a basin under the patient's bed containing some carbolic lotion, the end of the rubber tube being kept under the surface of the liquid.

Of course, the great object of the operator should be to evacuate the fluid without admitting air. The writer in one case found that air was admitted owing to the struggles of the patient—a very nervous child, an excellent and rapid recovery ensued without a bad symptom.

It is generally not advisable to remove all the fluid in the pleura, but the writer finds that the slowly flowing capillary stream from a Southey's canula may be safely permitted to run till the cavity empties itself. It is different with the quickly acting aspirator,

and, as a rule, the quicker the flow the greater is the danger of syncope, coughing, or dyspnoea. Should such symptoms supervene the suction must be discontinued for a time without withdrawing the needle or canula, and as soon as marked embarrassment supervenes, the operator had better withdraw the canula and trust to nature for the absorption of the remaining fluid, which always happens. Some operators insist that more than 20 oz. should never be removed at the first tapping.

After withdrawing the canula, a small pad of lint, soaked in any antiseptic liquid, may be quickly placed upon the site of puncture where it can be fastened by a few strips of adhesive plaster. Coughing, if it continues, may be relieved by a hypodermic injection of Morphia, or by tightly bandaging the chest with a deep or broad binder.

After the operation is concluded, the organs, which had been displaced, may be found partially restored to their normal position and day by day the physical signs become nearer to the normal. Sometimes a second or third tapping may be required. Should pus be found at the first time of withdrawing the fluid, or at any subsequent time, the treatment described under Empyema, on page 266, will then be considered advisable. The utmost care must be taken to prevent an ordinary pleural effusion from being converted into a purulent one. This may be caused by the use of soiled instruments or by the admission of air during the tapping.

Sometimes a thickened pleura or a large deposit of lymph may give rise to difficulties in getting out the fluid. The latter may be pushed in front of the trochar and canula, but the experienced operator after he has punctured the skin by the instrument takes a short grip of the latter as he causes it to penetrate the remaining tissues with a sudden push or jerk, which is certain to penetrate instead of pushing the membrane before it.

When the canula gets blocked there is some danger in attempting to clear it. The writer has driven out plugs of fibrin by forcing back some of the fluid out of the aspirator cylinder but this should not be attempted unless the instrument has previously been rendered aseptic both inside and out, and only when the fittings are absolutely air-tight.

The canula with stop-cock, mentioned under Empyema admits of being easily cleared of obstructions by pushing back the trochar without the possibility of air being admitted at the same time, and this is a great advantage.

Where localised or circumscribed collections of pus are found, each cavity may require to be separately punctured and tapped.

Lewaschew has introduced a method of treating pleuritic effusion which appears to be a distinct advance, and it can be used also in purulent cases. Its object is to do away with the untoward results which sometimes occur from the disturbance of the balance of intrathoracic pressure. He withdraws a small amount of the fluid until some uneasiness is felt by the patient,

and then he injects, by a reversed action of the aspirator or siphon, an equal amount of a sterilised solution of Chloride of Sodium (7 per cent. in distilled water). After the balance is thus restored he continues the aspiration for a time, and again reverses the action, injecting in more saline solution until little but pure solution is left behind. Where no adhesions exist this method gives excellent results in pleurisy and empyema.

The diet after tapping should be of the most sustaining nature, and every remedial agent calculated to improve the general nutrition should be given, as Tonics with Iron Quinine, and Cod Liver Oil, change of scene, &c. Where a tendency to re-accumulation occurs, and when the residual fluid after partial emptying of the pleura appears slow in disappearing, the treatment already mentioned must be persisted in as blistering or counter-irritation, Iodides, and Diuretics, with Saline purgatives like Friedrichshall, Carlsbad Salt, or Hunyadi Janos Water.

Chronic dry pleurisy is best relieved by blisters or strapping. Cereville in dry pleurisy injects sterilised Olive Oil to diminish pain and aid resolution.

The frequent association of pleuritic effusion with tubercle makes anti-tubercular agents take a prominent part in the after-treatment.

PLEURODYNIA.

The treatment of this affection will consist in the exhibition of the remedies suitable for muscular rheumatism or neuralgia. (Gowers believes that pleurodynia is a true neuralgia.) In acute cases one or two full doses of Salicylate of Sodium (30 grains) given after a hot pack, or a Turkish or hot air bath, often act very speedily.

After making an impression upon the pain in this way, the effect may be kept up by smaller doses or by 8 or 10 grain doses of Antipyrine every six or eight hours. Salol, in doses of 15 to 20 grains, is a most trustworthy remedy. After the acute symptoms have subsided, or in chronic cases from the first, alkalis in full doses, in conjunction with the Iodide of Sodium or of Potassium, should be given.

R. *Sodu Iodidi* *ʒii.*
 Potassu Bicarbonatis *ʒj.*
 Tinctura Aclææ Racem. *ʒvj*
 Mistura Camphoræ ad *ʒxii. misc.*

Fiat mistura. Capiat cochleare magnum ter in die post cibos.

Quinine, though highly recommended, has seldom been of any use in the writer's hands, but in very chronic cases Arsenic is valuable when given in combination with Iron in anæmic subjects.

Guaiacum in chronic cases is often valuable and may be combined with Sulphur.

Local treatment is of greatest service. If the pain is unbearable the speediest remedy will be a hypodermic injection of Morphia (4 grain) given directly over the pained region, and if the patient must move about his business the chest should be strapped in Roberts method so as to entirely restrain the movements of the affected side. This generally affords instant relief if properly done. Any of the various anodyne liniments may be useful. The Belladonna and Opium plasters may be used for the strapping. A piece of lint saturated in a mixture of equal parts of liniments of Belladonna, Aconite, and Chloroform, may be laid upon the part and covered over with oiled silk and a bandage. Menthol or Chloral and Camphor, may be rubbed over the part.

Cupping, blistering, or smart counter-irritation with Iodine, Mustard, Croton Oil, Chili Paste, or Tartar Emetic Ointment, may be used. The continuous current or static electricity is often very useful. In severe cases acupuncture after freezing with the Ether spray may be tried.

PLEURO-PNEUMONIA—See under Pneumonia.

PLUMBISM.

The treatment of acute poisoning by the Salts of Lead will be stated under the head of Poisoning. In chronic lead poisoning the patient should be persuaded to give up his occupation for a time if it be clear that the lead got into his system in this way. Minute examination of the patient and his surroundings should be made to determine the source of contamination, and this should of course, be stopped at once. The symptoms may require immediate relief. Thus the violent pain of lead colic must be relieved by a hypodermic injection of Morphia, but no permanent relief can be counted upon till free purgation is established. Two drugs give excellent results. Sulphate of Magnesia and Castor Oil. When very obstinate constipation exists, 1 oz. Castor Oil, in combination with half a minim of Croton Oil, may be given. For prolonged use the Sulphate of Magnesia, in small morning doses, is to be preferred.

Iodide of Potassium is of the greatest value. It forms a soluble salt with the lead in the system, and this appears after a time as the urine. It may be given in any form, and often acts best when combined with the Saline purgative just mentioned. 5 grains of the Iodide may be given three times a day after meals, and 1 drachm of the Sulphate of Magnesia three times daily before meals, or both may be given in one mixture.

The basis of all rational treatment consists in giving a substance which will form a soluble salt with the lead deposited in the tissues, this gets the lead into the circulation from which it is rapidly excreted by the kidney and mucous membrane of the intestinal surface. Hence the Iodide is of little use unless in con-

junction with Sulphate of Magnesia, which in the bowel meets the soluble lead salt and forms the sulphate of lead, which is removed by purgation before it has time for being absorbed.

Alum is also of use, and, combined with Opium, it often is found to purge gently in painter's colic.

Sulphur Baths, or baths of the soluble Sulphides or Sulphurets, are recommended, but there is room for doubting their usefulness. Sulphur internally is beneficial, and the Sulphite of Soda in 5-to gr. doses often relieves colic.

The rectal injection of the vapour of Ether has been found useful in the treatment of lead colic, and it may be tried in lead convulsions followed by coma, but here Nitrite of Amyl should be given.

Semmola placed the patient in an acidulated bath, and laid one pole of the continuous current upon the tongue, whilst the other pole was dropped into the water. Though no lead was found upon the sides of the bath or in the water, the urine was found some days afterwards to show that increased elimination was taking place. The bath was then dispensed with in other cases, and one pole was placed upon the tongue, and the other upon the pit of the stomach, or one pole over the vertebral column, and the other over the stomach. In all cases the urine showed increased amounts of lead, and the blue line disappeared in about three weeks, except in those cases where saturnine encephalic symptoms were present.

Electricity is the remedy for local paralytic lesions, and it may be used with advantage even when no paralysis is observable, but where the reaction of degeneration is present. The continuous current may be applied to the affected muscles and to the nerves supplying them. The induced current may be also occasionally used. This treatment should be patiently persisted in for long periods. Massage may be tried in conjunction with it, and the results just mentioned as obtained by Semmola suggest that the beneficial effects of the current may be possibly owing to the increased elimination. Erb has suggested galvanisation of the spinal cord, which probably would be beneficial in the same way. (See also under Colic, on page 154, and under Paralysis, on page 659.)

The prophylactic treatment of all persons subjected to the action of lead is of the utmost importance. The most rigid attention to personal cleanliness is essential. Painters who never eat in their paint-shops, and who always carefully wash their hands before meal times, escape, whilst their less scrupulously clean companions suffer. Where the dry dust of any lead compounds saturate the air of work-rooms or manufactories the workers should be educated to keep their mouths closed, and do all the breathing through the nose, or respirators and overalls should be worn, and the freest possible ventilation be insisted upon.

Lemonade made in the ordinary way, but containing free

Sulphuric instead of Citric or Tartaric Acid, has been found useful, or the Acid may be administered in conjunction with a ~~morning~~ dose of Sulphate of Magnesia in very dilute solution. A diet into which milk largely enters is also valuable, and workers in lead industries should not be permitted to commence work before breakfast.

PNEUMONIA.

There is much that is most unsatisfactory in the present aspect of the treatment of pneumonia. Mild cases of the disease do well with almost any treatment, but there are grave differences of opinion regarding the best methods of dealing with the worst forms of the disease.

The writer believes that what is at present called pneumonia is but a local or secondary manifestation of several totally distinct constitutional affections which we are not yet able to differentiate, and which are probably caused by several distinct microbes. The first satisfactory progress in the treatment of pneumonia will begin after the natures of these separate affections have been demonstrated.* For the present the physician must be content to treat pneumonia upon the same rational lines as are indicated in the management of the continued fevers, with such modifications as the extent, nature, and severity of the local pulmonary lesion will suggest, taking care to steer his way clearly between the warm bed and peppermint water treatment, and the heroic calomel, blood-letting, or alcoholic plans.

In the very early stage the patient is, of course, to be put to bed, to have a moderate amount of light clothing, and an abundance of fresh, pure air, a milk diet, and a liberal amount of water to drink.

The popular idea of the danger of draughts should compel the physician to superintend the ventilation and heating of the sick room. A few screens, covered with light muslin, and about six feet in height, should be placed at a little distance round the patient's bed, which must not be in a corner of the room.

With such a contrivance as this, doors, windows, and ventilators may be safely left freely open, even in moderately cold weather.

The most that should be attempted in the way of drugs should be the administration of a mild Saline Cathartic alone or preceded by 3 grains of Calomel. When the bowels have been thus cleared out, the hot skin may be made to act, the cough may be soothed, and the pain in the chest relieved by a simple combination like the following:—

R. *Liquor. Morphine Hydrochlor.* ℥j.
 Liquor. Ammonie Acetatis ℥ij.
 Lim. Antimonialis ℥iij.
 Aque Camphoræ ad ℥viij. misce.

Fiat mistura. Capiat coch. mag. quartâ quâque horâ

* See a paper by the Author in the *Dublin Journal of Medicine*, April, 1891.

With the administration of the above, large hot Linseed poultices may be applied every three or four hours. It is best to redden the skin well at the start by Mustard, and to keep up the effect afterwards by plain linseed, or the plan of combining a pure mustard and simple linseed poultice, as mentioned upon page 690, may be adopted. The poultices should be spread upon flannel, and should extend from the spine to the sternum of the affected side.

Where these simple measures fail to relieve the pain in the chest, a larger dose of Morphia may be given hypodermically, but though this pain is probably owing to some pleuritis which is constantly present in pneumonia, the same freedom in the use of anodynes is not admissible, owing to the danger of interfering with the expectoration and its evacuation. With care, however pain at this stage can generally be entirely relieved by opiates. Mitchell Bruce has drawn attention to the necessity of Morphine for the relief of pain in pneumonia, and has shown that it often is of the greatest use and may save life.

Hot fomentations (to which any of the innumerable anodyne liniments can be added), cupping, blistering, and leeching may be considered necessary. A method used by Goodhart and Fieandt with marked success consists in applying continuously a large rubber ice-bag over the affected lung. After several hours of this application, pain may disappear, cough may lessen, and very often a marked fall in the fever heat takes place, so much so that many Continental physicians use the ice-bag as an antipyretic. Cold compresses may be tried as a sort of compromise between this treatment and that by hot poulticing or fomentations. Kolpinski uses hot water (110° F.) bottles, containing 1 gallon each, and places them on each side of the patient's chest, and has them refilled every 45 minutes for days, and he claims that this method will cause the disease to abort.

Formerly blood-letting was freely practised for the relief of pain and with the view of cutting short the disease. There cannot be a doubt that as a routine method this raised the death-rate, and it is very probable that many patients died from the heroic blood-letting who would have lived had nothing whatever been done for them. Nevertheless, it is just as likely that some few patients nowadays are permitted to die for want of blood-letting. With a firm, incompressible pulse in a strong plethoric subject who is suffering from *dyspnea* or much pulmonary embarrassment and *livid* blood-letting may still be relied upon to turn the scale in the patient's favour.

Leeching will not accomplish this. This slow method of removing a small amount of blood will not produce any marked benefit in severe cases, though it may relieve local pain, but in conjunction with a smart Saline purge and the application of one or more cupping-glasses over the leech-bites a good effect has been several times obtained by the writer.

Much has been written about the value of Digitalis in the early stages of pneumonia, and the extraordinary discrepancies in the reports are remarkable. The writer, after studying the literature of the subject, is convinced that many authorities in criticizing the results of others appear to have strangely overlooked the question of dosage. Those who affirm that digitalis is useless generally have used it in doses which are a mere fraction of the doses employed by those who extol it. Thus Rubel has treated 1,200 cases with a mortality of about 2½ per cent., he gives 1 to 3 drs. daily, and states that the disease is controlled in 3 days. Petresco claimed to have treated 755 cases with a mortality of 1·22 per cent. All his patients felt quite well in 24 hours after the jugulation of the disease, which occurred at the end of 3 days. This abortive treatment was carried out in all his cases without a single symptom of poisoning by daily doses of 60 to 120 grs. digitalis leaf made into an infusion with water, and given in divided doses every half hour. This he maintains is the true therapeutic dose, and says from it can good results be obtained. The writer has no experience of the method, but the statements of Petresco are corroborated by many others, and the plan should receive attention, as its value or worthlessness, and its danger or safety, would appear to be easily proved in large hospitals. Already many reports of alarming collapse and protracted convalescence are forthcoming. More recently Maragliano has supported this treatment by some striking evidence obtained by experiments on animals, and he maintains that digitalis neutralises the toxins of the disease in a very specific manner, and by mixing the drug with virulent cultures of the pneumococcus these become quite innocuous. He has also demonstrated that an animal which has received a fatal dose of the toxin can be saved if injected at the same time with digitalis. He gives one drachm of digitalis in infusion during the first 24 hours to an adult, and in a severe case another drachm in the next 24 hours. This dose is equivalent to about 1 oz. of the B.P. tincture daily. Frankel reports good results from daily doses of 1 dr. of the leaf. He says the drug should only be used in the very early stages, and he does not give it in those cases where he believes that cardiac weakness is present. The case of Quinine stands in the same uncertain position as digitalis does in the treatment of pneumonia. Thus for it Juergen claims extraordinary success, but he gives in one dose 15 grs. to infants under 12 months and 77 grs. to adults, and attributes it always reduces the temperature and is quite safe when the fever is intense.

The temperature should be watched closely, and when, say, 104 or more degrees are recorded, it will be wise to consider what is to be done to reduce it. Various measures are feasible.

The ice-bag applied to the chest, as already mentioned is sometimes effectual, and it relieves pain at the same time, but it may aggravate pain in some cases, Leiter's tubes may be used

The cold pack has its numerous advocates. Mays gives the results of 156 cases treated by the local application of ice, with a total mortality of 320 per cent.

Fenwick has introduced an excellent plan for the abstraction of body heat by a constant current of cool air. He has demonstrated its value in pneumonia. It consists of a large and wide iron surgical cradle, from the central bar of which are suspended several small zinc pails half filled with ice. The patient, covered with a light sheet of opaque gauze, lies undressed upon the bed, and the cradle, covered by a light counterpane, is placed over him, a hot water bottle is placed at his feet. This plan may be kept in operation for many days, and when hyperpyrexia threatens, cold sponging may be tried in addition.

Cold baths are greatly used on the Continent in the treatment of pneumonia, and some authorities use them as a routine method even when the temperature does not exceed 102° or 103° F., and claim a low mortality. A bath of the temperature of 60° to 80° is employed, and the patient is immersed for 15 to 25 minutes, the pulse and temperature being closely watched. In mild cases one must conclude that they are often unnecessary, and the difficulty of lifting a weak patient into and out of a bath is not one to be lightly undertaken in a disease in which the main principle of treatment should be to husband or save up any scrap of strength which the patient possesses. In such cases it has always appeared to the writer more rational to resort to cold sponging or wet compresses. It does not do away with this objection to quote a low mortality where the cold bath is used in a routine way, for the mortality might be still further reduced if the use of the bath was confined to selected cases. In hyperpyrexia with a fever heat of 106° or more, the cold bath is the best agent which we possess, and undoubtedly it affords the patient the best chance for life. Under such conditions all other antipyretics should be abandoned as waste of time in dealing with pneumonia.

The patient may be kept in the bath till the temperature falls to about 100° , and the heat of the bath may be reduced to 40° in severe cases. As the fall continues after his removal to bed, it is seldom wise to wait till the fever heat falls entirely to the normal during the immersion. Where there is much prostration the heat of the bath may be gradually reduced from about 80° F. at the beginning of the immersion to 50° F. at the end by adding cold water or ice. A full dose of stimulant may be given before the patient leaves his bed, and this may be repeated while in the bath or after he has been laid in bed again. The effect upon the pulse, temperature, and general condition is to be the guide when the question of repeating this treatment crops up again in four, six, or eight hours after the bath.

The question of the value of antipyretic drugs in pneumonia is one about which there are grave differences of opinion. Upon the whole the balance is decidedly against their use. They bring

down the fever with certainty, but often without benefit in pneumonia, and it appears to be accepted by the best authorities that save in cases of hyperpyrexia the mere reduction of temperature is of little moment, and since there is no antidote to the disease the symptomatic treatment of the heart is perhaps with our present agents the best point to watch.

Quinine in moderate doses, 3 grs. every four hours, has many advocates, and Yeo believes that its value does not hang upon temperature reducing qualities, but that it tends to destroy the germs which cause the fever. The writer does not think it an even in these doses where the breathing is laboured and there is much expectoration.

Salicylates have their advocates, and Aconite, Veratrum, Antimony, and other drugs of the same class give good results but only in the early stages. Recently much has been written on the value of Salicylic Acid or the soda salt as a routine treatment, and though several observers regard it as almost a specific others attach no value to it save as an agent for the reduction of temperature or for favouring of elimination.

As failure of the heart's action is one of the most frequent causes of death in pneumonia, the pulse should be watched from the very onset of the attack, and as soon as the least sign of cardiac failure is noticeable the free exhibition of Alcoholic stimulants is indicated.

It is not advisable, however, to order Alcohol in a routine fashion in all cases of pneumonia from the beginning. In the early stages it may do harm. When the pulse shows signs of weakness and frequency the stimulant should not be withheld, but with a pulse of 120, and compressible, one is not justified in withholding a large amount of alcoholic stimulants, considering our present knowledge of the disease; 8 to 12 oz., or more daily of good Whiskey (of at least five years old) may be given in severe or desperate cases. It is better to give the whiskey in milk—a table-spoonful may be given in a large wine-glass of milk every hour or every two hours.

The writer believes that one serious mistake is often made in such cases—the patient being able only to take a small amount of nourishment, the physician or nurse insisting upon the alcohol. It may then become almost the only thing the patient takes. Alcohol in small doses, however, must be regarded as a valuable food in a condition like that under discussion altogether apart from its action upon the heart.

Food is of vital importance from the beginning, and if more attention was bestowed upon it there would often be less necessity for thinking of alcohol. Beginning with milk, beef tea and soups or beef essences should be liberally administered, and the effect of large quantities of a carefully-prepared beef tea upon a failing cardiac muscle is not to be lost sight of. Though such a dietary can hardly be expected to build up tissue in a state of

that in which the pneumonic patient is in, it certainly will tend to prevent tissue waste, and may save the patient's life by saving his cardiac muscle. The danger of over-stimulating the heart must not be lost sight of. Brandy may be given instead of whiskey; but, as a rule, wine in any form is inferior to these.

Digitalis has been strongly recommended in the treatment of the heart failure, and in ordinary doses most authorities must admit that it often fails. If Petresco's statements are corroborated dosage should be changed, but it must be insisted upon that his results are obtained in the early stages and by the antipyretic action of the drug. The cause of the failure of the drug to influence the failing heart in pneumonia is probably to be found in the high temperature present.

Where cardiac power is failing, in spite of the free exhibition of alcohol, and where the breathing and cough are troublesome, the following combination may be tried.—

R. Spirit. Ammon. Aromat. ℥iss.
 Spirit. Æther. Sulph. ℥j.
 Tinct. Digitalis ℥iij.
 Moschi gr. lx.
 Vin. Ipecacuanha ℥vi.
 Tinctura Cinchona ad ℥vi. misce

Fiat mistura. Capiat ℥ss. ex ℥iij aqua quartis horis

Caffeine or the very soluble double Salt—the Sodio-Salicylate—is safer than digitalis, and acts more rapidly in cases of cardiac failure. One grain may be given every three hours in conjunction with stimulants. Sparteine may be pushed with safety.

Under conditions like those just mentioned, blood-letting is still advised by some, but the benefits to be expected from it get less and less as the disease advances, and at this stage it would appear to be unjustifiable, unless in the presence of great dyspnoea and lividity, with a full pulse.

For cardiac failure in pneumonia there is, perhaps, no drug to be compared with Strychnine in full doses, and the writer does not hesitate to recommend it in full hypodermic doses under these circumstances. It will certainly save life in some cases, and Kidd is probably right when he affirms that it acts by counteracting the nervous exhaustion, which is the direct effect of the toxins. 3 to 5 minims of the liquor may be injected every 2 or 3 hours for 4 doses till the pulse and respirations respond. The writer has seen surprising results from this practice in the pneumonia of influenza.

Sleeplessness will require careful management, and before the introduction of the valuable hypnotics of recent years, there was nothing before the physician but the ice-cap and Opium or Morphia. As already stated, there is risk in giving narcotics on account of

the nature of the expectoration, though many authorities recommend Opium all through the attack. Chloral is decidedly objectionable. In the opinion of the writer, its use in pneumonia is unwarrantable, owing to the danger of its cardiac depressant action.

Sulphonal, given in a little whiskey punch, Paraldehyde and Trional are safe and efficacious. The cold bath often relieves the delirium, insomnia, and dyspnoea when the symptoms are dependent upon or associated with a high temperature if asthma is not well marked.

Where a large extent of lung is involved and dyspnoea is urgent much relief may be obtained by inhalations of Oxygen, which can now be readily procured in cylinders and with a simple tube, which does away with the necessity of rubber bags and masks of all kinds. This remedy has failed in much that was expected of it, but it is certainly of value in those cases where the aim of the physician is to meet symptoms and tide the patient over serious embarrassments about the time when the crisis may be expected. It may be given continuously for hours and even days when allowed to mix with the air near to the patient's face. Nausea and Nitroglycerin often do harm in those cases where the blood pressure is low.

The above measures may be expected to save life in those severe and desperate cases which probably would succumb to a purely "expectant" treatment, though there is no doubt mild cases and sometimes every case in a mild epidemic, may be successfully treated by the expectant method.

The Serum treatment of pneumonia is still exciting interest and since the antitoxin for diphtheria has met with support many workers are busy in this department. The results obtained by injecting the serum from patients just recovered from the disease as yet have not been striking, and little more can be said in favor of the serum prepared from animals rendered immune. In the view which the writer has long held after clinical study he corrects this method of treatment is not likely to be successful, i.e., that the diseased condition recognised as pneumonia is the manifestation of poisons or toxins produced by several totally distinct micro-organisms.

Other plans of treating pneumonia are being extensively tried and most encouraging reports are published of the results, but as the writer has no personal experience of their use, he need only briefly refer to them.

Clements has been treating pneumonia by inhalations of Chloroform during the last 40 years, with only two deaths at the beginning of this period. He mixes the chloroform with alcohol and saturates a piece of firmly twisted lint with the mixture. This is wrapped up in dry cotton, and held near to the patient's mouth and nose, so as to permit of the vapour being freely mixed with air. Narcosis is not to be produced. He claims for this treatment

that it defibrinates the blood and modifies the local process of inflammation, so as to generally prevent hepatisation, and that it hastens the termination and leads to the rapid disappearance of the physical signs of the disease.

Numerous observers report glowingly of Calomel, and Strong reports 20 cases treated successfully by doses of 20 grains every three hours, with no ptyalism and little catharsis, and Nitrate of Silver and Protargol have their advocates. Pilocarpine has failed to sustain the glowing reputation given to it by its introducer.

Iodide of Potassium has been successfully given in doses of 15 grains every 3 hours during the day and night by Nilsson.

Cunningham injects subcutaneously 4 to 12 ozs. daily of Saline Solution (1 dr. Chloride of Sodium to 20 oz. water), and believes that the hypodermoclysis strengthens the heart and prevents blood clots.

During the later stages of the pneumonia, after the temperature falls, and the immediate danger seems to have passed, the greatest care should be exercised, as the heart may still require assistance. Stimulants should be continued for a little time in full and then in gradually diminished amounts, but all antipyretic or depressing remedies must be carefully avoided, and the horizontal position maintained during convalescence. The most liberal diet is to be kept up, and the following tonic, or anything possessing similar action, may be safely administered. Fellow's and Easton's Syrups are valuable.

R. *Liquor. Strychninæ* ʒiss.
 Acid. Nitro-hydrochlor. Dil. ʒv.
 Quinnæ Sulphatis ʒss.
 Infus. Calumbæ ad ʒviij. *misce.*

Fiat mistura. Capiat cochleare magnum ex paululo aquæ ter in die ante cibos.

PNEUMOTHORAX.

The treatment of pus in the pleural cavity, which is so often associated with the presence of air at the same time, has been mentioned under Empyema, upon page 266. In those cases where air has suddenly found its way into the cavity by perforation or rupture of the visceral pleura without external injury, recovery often follows if the patient is kept quiet. Where pain is distressing, small inhalations of Chloroform, cupping, venesection, or hypodermic injections of Morphia may be tried.

Where there is evidence of the air within the thorax being at a higher pressure than the outside atmosphere, as proved by the great distension of the side and marked displacement of organs, tapping by a fine trochar and canula is necessary. It is generally held that this should not be done till a sufficient time has expired

in order to allow of the closure of the aperture in the visceral pleura through which the air originally passed outwards. Albersheim has, however, shown that frequent tapplings do not prevent closure of the aperture, and they effectually prevent the formation of such adhesions as are fatal to the future thorough expansion of the lungs. Where the pneumothorax is the result of tubercular disease, it is held to be a mistake to resort to tapping.

The best rule for guidance should be that no operative interference is to be undertaken, except in the presence of very marked pain and distress, and then it will generally be found sufficient to tap with a fine trochar, so as to permit the free escape of the imprisoned air, till equilibrium is established, after which the side should be carefully strapped to prevent distension again. A drainage tube may be left in where there is much fluid or fever, but as a rule, when this is the case, the larger opening desirable in doing the ordinary empyema operation should be made. Bouverst recommends the internal use of Opium to stop all coughing, and he insists that the canula should be left *in situ*.

In one case recently seen by the writer the left pleura had suddenly filled with air after a violent run up stairs, the heart was found beating in the right axilla, there was great dyspnoea on the least exertion, but no fluid. The case perfectly recovered by placing the boy at absolute rest in bed.

POISONED WOUNDS—See under Wounds and Septicæmia.

POISONING.

In the treatment of poisoning, the first consideration in the great majority of cases will be to evacuate the contents of the stomach when this is possible. This may be accomplished by emetics or by the stomach-pump, or by tickling the fauces when these agents are not at hand. In poisoning by the strong mineral acids and all corrosive substances the stomach-pump is contra-indicated, but in the case of corrosive substances like carbolic acid this may be used cautiously if a soft tube be employed. Indeed, the soft India-rubber tube of the stomach-pump can scarcely do any harm except in the most destructive instances of poisoning by concentrated sulphuric or nitric acid, and the pump should always be fitted with such a tube in at least two sizes. When at hand the pump should be preferred to every other means of emptying the stomach, and except in the limited number of cases just mentioned, it may be used even when there is room for considerable doubt in the diagnosis of poisoning in patients found in insensible or comatose conditions. The coroner's court will justly censure the practitioner who has been in attendance upon a patient picked up in an insensible condition if the evidence afterwards produced proves that a narcotic poison had been swallowed though when seen by the physician no such evidence had been forthcoming and the

symptoms pointed to head injury, uræmia, or apoplexy. The cautious use of the pump with the rubber tube, when scientifically carried out, can in no way injure the patient's chances of recovery should the case ultimately turn out not to be one of poisoning; and as every minute's delay may be serious for the patient, and as there is thus short time for counsel and debate, he should be prepared to act accordingly and make his error upon the safe side.

The first time of using the stomach-pump is sure to be a bungling affair if the operator feels timorous or nervous. The tongue being depressed by the left index finger as the patient is seated in a chair, with the head well steadied by an assistant, and the gag in position, the tube is to be pushed steadily, boldly, and rapidly through the mouth, pharynx, and œsophagus till the stomach is reached. Though it is more difficult to pass the soft rubber tube, the confidence in its perfect harmlessness will be of great importance to the novice. He should not be deterred by the sound which may be produced by air passing through the tube as its extremity glides past the epiglottis; this ceases as the rubber is passed home into the stomach. During the pumping, by reversing the action of the levers, a little water may from time to time be sent into the stomach to clear the tube of any solid obstruction, and before withdrawing it finally tepid water should be injected into the organ, and this should be pumped out again, the operation being continued till the washings return clear. The antidote may be mixed with the water, and in many instances a quantity of this should be left in the stomach. In pumping opium or alcohol cases, after the washings return clear and free from odour, the stomach may be partially filled with strong infusion of tea or coffee.

The Syphon Tube may take the place of the stomach-pump in most cases.

30 grains of Sulphate of Zinc or 10 grains of Sulphate of Copper in a tumblerful of tepid water will prove efficient emetics, and Apomorphine, $\frac{1}{2}$ grain injected hypodermically, acts with great certainty and rapidity when the patient is unable to swallow. Notice should be taken of the fact that though patients may often take Apomorphine in doses of $\frac{1}{2}$ to $\frac{1}{4}$ grain by the mouth without experiencing nausea, this dose would probably prove fatal if given by the hypodermic method, owing to its rapid depressant effect upon the heart.

Mustard in dessert-spoonful doses, in copious quantities of tepid water, may be used when the above emetics are not at hand. Ipecacuanha and Antimony are too slow in their action to be depended upon.

The contents of the stomach when ejected (or when obtained afterwards upon opening the body) should be carefully preserved for further investigation. This is often overlooked in the exciting period of treatment.

The writer has several times successfully pumped and washed out the stomachs of infants and very young children with a *cat* India-rubber male catheter, attached to the nozzle of an ordinary large glass or metal syringe.

The following formula may be employed as a *general Antidote for any poison of unknown nature*.—

Calced Magnesia	}	Equal quantities
Powdered Wood Charcoal		
Hydrous Peroxide of Iron		

Half an ounce of each of these may be given in a tumblerful of water every half-hour till three doses be taken.

The following brief alphabetical list of poisons, and their antidotes and treatment, is taken from the 7th Edition of the Author's work on "Pharmacy, Materia Medica, and Therapeutics" page 619, and may prove useful for reference in emergency—

Acetanilid or Antifebrin.

The stomach-pump or an emetic of Carbonate of Ammonia should be used, followed by Strychnine, $\frac{1}{4}$ grain hypodermically, and external warmth. Where cyanosis is marked, inhalations of Oxygen may be given, and free stimulation with Alcohol.

Acids, Mineral.

The stomach-pump should *not* be used. Alkalies—Lime, Soap, Chalk, Potash, Soda or Magnesia—moderately diluted with water may be freely given. In the absence of these, plaster off a wall (softened by hot water), oils (Almond or Olive), and small doses of Morphine hypodermically shall be administered; all food should be given by the rectum. At a *late* stage, when the danger of perforation has passed off, bland mucilaginous foods, like barley water, linseed tea, and white of eggs, may be freely given.

Acid, Prussic (or Hydrocyanic).

The stomach, if possible, should be emptied by the stomach-pump or by a rapid emetic ($\frac{1}{2}$ dr Sulphate of Zinc), hypodermic injections of Atropine ($\frac{1}{2}$ gr), 2 minims of the 1 in 100 Solution of Atropine may be given and repeated in 30 minutes if necessary. Ammonia, or Whiskey, inhalation of Oxygen, Ammonia, or Chlorine, cold and hot affusions alternately, and *artificial respiration*, are the best agents to resort to.

Freshly precipitated Oxide of Iron, followed by a solution of Carbonate of Potassium, is to some extent a chemical antidote, but *free stimulation* after the evacuation of the stomach must be alone relied upon.

Aconite, and Hellebore or Veratrine.

The stomach-pump or emetics should be used; $\frac{1}{4}$ gr Apomorphine hypodermically, or a table-spoonful of mustard in warm water, or $\frac{1}{2}$ to 1 dr Sulphate of Zinc should be given as soon as possible. Stimulants—Whiskey and Ammonia hypodermically, with 20 to 30 minims of Tincture

By Aconite—Continued.

of *Digitalis* or 2 minims Liquor Atropinæ should be then administered. Strychnine may be given ($\frac{1}{10}$ gr.) by mouth, rectum, or hypodermically.

The patient should be kept horizontally on his back with his head lowered, and in a state of absolute rest, and sinapisms applied to the heart and extremities, and dry heat, friction, and artificial respiration kept up unceasingly. Murrell recommends inhalations of Nitrite of Amyl.

Alcohol.

The stomach-pump should be promptly used, and the stomach filled through it with strong coffee, to which a little Ammonia should be added; or a hypodermic injection of 10 minims Apomorphine Solution may be given in the absence of the pump, sinapisms cold affusion, Nitrite of Amyl inhalation, or Electricity may be tried, and in *dysæsthesia* cases, boiling water may be used to cause immediate venication of the skin over the soles of the feet. The hypodermic injection of $\frac{1}{10}$ gr Strychnine is of unquestionable value, and Mindererus Spirit in 2 or 3 doses may be given. Warmth to the surface is essential. (See also page 28.)

Ammonia and Alkalies.

The stomach-pump should *not* be used. Weak acids (Acetic preferable) may be given, largely diluted, and followed by draughts of Almond or Olive Oil or of melted butter, and demulcent drinks.

Tracheotomy may be required for the œdema of the glottis, and Morphine hypodermically for the shock.

Aniline.

The stomach-pump should be used and free washing out of the organ accomplished, after which artificial respiration and Oxygen inhalations, and Strychnine injected hypodermically ($\frac{1}{10}$ grain), and the treatment detailed under Acid Prusic may be tried.

Antimony (Tartar Emetic).

Stomach-pump or emetics are not generally required, as vomiting sets in soon. Tannin, strong tea, or Gallic Acid, or any diluted astringent mixture or infusion containing tannin may be freely given, followed up by the hypodermic or rectal administration of Alcohol, to which small doses of *Digitalis* or Strychnine may be added. White of egg, barley water, or linseed tea may be given freely, and the patient kept in the prone position.

Butter of Antimony.—The treatment of poisoning by this preparation of Antimony should be the same as for Mineral Acids—viz., Magnesia, Soap Suds, Chalk, Potash, or Soda, followed by Oil and Milk.

Antipyrin.

After stomach-pump, free stimulation by Alcohol, followed by hypodermics of Strychnine ($\frac{1}{10}$ gr.). External warmth and Oxygen inhalations where there is much cyanosis.

Arsenic.

The stomach-pump or emetics, or 10 minims of Apomorphine injection, should be employed even when vomiting has already taken place. Freshly-prepared moist Peroxide of Iron (prepared by adding Soda or Ammonia to the Tincture of Iron, and filtering rapidly through muslin or cambric) or

By Arsenic—Continued.

Dialysed Iron in ounce doses, diluted, or, in the absence of these, Magnesia freely, or Animal Charcoal, Olive Oil, or Lime Water, must be freely given; demulcent drinks and stimulants by mouth or rectum are also indicated. Large doses of Castor Oil are essential to clear out the intestinal tract and to prevent further absorption.

The following method of using the iron antidote is convenient.—3 oz. of the strong Liq. Ferri Perchloridi is poured into a pint measure, which is filled up with water; 1 oz. of Calined Magnesia is then mixed with another pint of water; both solutions or mixtures are then to be thoroughly shaken together, and a dose of one table-spoonful should be given every 5 or 10 minutes.

Atropine and Belladonna.

The stomach-pump or emetics, and afterwards the following are to be given:—Tannin or Tea, Charcoal, Morphine ($\frac{1}{2}$ grain) by subcutaneous injection, or Laudanum by the mouth, or Pilocarpine ($\frac{1}{2}$ grain) subcutaneously, followed by purgatives.

The poison being excreted by the kidneys, the bladder should be emptied by the catheter to prevent reabsorption. Esarine in small doses has been advocated as an antagonist, but pilocarpine is better. Free stimulation, counter-irritation, and artificial respiration may be necessary.

Cannabis Indica.

The stomach-pump or emetics, especially Apomorphine hypodermically (10 minims of B.P. injection), are to be given, and the symptoms treated as they present themselves. It will generally be found necessary to both purge and stimulate.

Camphor.

Stomach-pump or emetics, and copious draughts of water, with tea Saline cathartics, and general counter-irritation, or cold and hot douches alternately, afford the best means of dealing with this poison.

Cantharides.

Stomach-pump or emetics, mucilaginous drinks, or, in their absence, Oils, Chalk, a little Opium by the mouth, and a Morphine suppository by the rectum, should be used.

Carbolic Acid.

The stomach-pump with its soft rubber tube should be used, after which the organ should be thoroughly washed out with pure Glycerin Alkali or Soluble Sulphates, as Epsom or Glauber's Salt, are antidotal, and Schöberl gives Saccharated Solution of Lime if the poison is still in the stomach. Give oils, egg albumin, and warm mucilaginous drinks, with any soluble sulphate, and finally, freely stimulate, counter-irritate, and give $\frac{1}{2}$ grain of Atropine. Though there is no known antidote, the writer is a case where half a cupful of the strong acid was taken in a fit of drunkenness—after the contents of the stomach were evacuated, washed that organ out repeatedly with pure Glycerin, using half a gallon of it, the Glycerin dissolving the excess of acid out of the swollen mucous membrane, and the patient made a good recovery. He has since satisfied himself that this is the best treatment whenever the strong acid has been swallowed; it does not interfere with the administration of soluble sulphates.

By Carbon Monoxide (Carbonic Oxide).

Water gas and coal gas owe their poisonous properties to the amount of this agent in their composition. Artificial respiration must be kept up after the removal of the patient from the poisoned atmosphere, and this must be continued for hours. Inhalation of Oxygen is to be used at the same time freely, and if the heart shows signs of failure, Strychnine may be given, and Faradisation of the phrenic nerve and rhythmic traction of the tongue should be resorted to. If all these fail and the patient's case appears desperate, venesection should be resorted to; fresh, healthy blood may be transfused.

Chloral Hydrate.

The stomach-pump or emetics, especially 10 minim injections of Apomorphine Solution should be used, and these must be followed by injections of Strychnine ($\frac{1}{2}$ grain) or of Atropine ($\frac{1}{4}$ grain), Caffeine (5 grs.), or free stimulation with Ammonia, Whiskey or Ether, and Sinapisms. *Particularly external warmth*, Electricity, and artificial respiration; inhalation of Amyl Nitrite may be tried. The patient should be roused and prevented from sleeping, and, as death may occur from the diminution of the body heat, warmth is essential. A pint of strong, warm coffee into the rectum, as advised by Murrell, may save life.

Dougall pointed out that Potash is an antidote to chloral, $\frac{1}{2}$ dr completely decomposing 80 gra. of chloral. He recommends drachm doses of B.P. Liquor Potassæ, largely diluted, every hour for several doses.

Chlorine.

When inhaled, must be treated by inhalations of Ammonia or Sulphuretted Hydrogen. If the poison has been swallowed it should be neutralised by large quantities of Albumen and mucilaginous drinks.

Chloroform.

When symptoms of an alarming interference with the breathing or circulation come on during anaesthesia, the tongue should be drawn forward, artificial respiration, cold affusion, free ventilation by a current of air, turning over the patient upon his left side, or inversion of the body, may be tried. For the König-Mass and Laborde methods see further on.

Hypodermically—Whiskey, Ammonia, Strychnine or Digitalis, or inhalation of Nitrite of Amyl, may be given. Strychnine is unquestionably the best of these and may be given hypodermically in one dose of 5 to 10 minims B.P. liquor. Galvanism is doubtful. If the chloroform has been swallowed use the pump, or give 10 minims of Apomorphine Solution, and proceed as if inhaled.

The following practical rules are appended to the report of the Hyderabad Commission, and the reporters state "that the Commission has no doubt whatever that, if these rules be followed, chloroform may be given in any case requiring an operation with perfect ease and absolute safety, so as to do good without the risk of evil":—

1. The recumbent position on the back and absolute freedom of respiration are essential.

2. If during an operation the recumbent position on the back cannot, from any cause, be maintained during chloroform administration, the utmost attention to the respiration is necessary to prevent asphyxia or an

By Chloroform—Continued.

overdose If there is any doubt whatever about the state of respiration, the patient should be at once restored to the recumbent position on the back.

3. To ensure absolute freedom of respiration, tight clothing of every kind, either on the neck, chest, or abdomen, is to be strictly avoided, and no assistants or by-standers should be allowed to exert any pressure on any part of the patient's thorax or abdomen, even though the patient be struggling violently. If struggling does occur, it is always possible to hold the patient down by pressure on the shoulders, pelvis, or legs without doing anything which can by any possibility interfere with the free movement of respiration.

4. An apparatus is not essential, and ought not to be used, as, being made to fit the face, it must tend to produce a certain amount of asphyxia. Moreover, it is apt to take up part of the attention which is required elsewhere. In short, no matter how it is made, it introduces an element of danger into the administration. A convenient form of inhaler is an open cone or cap, with a little absorbent cotton inside at the apex.

5. At the commencement of the inhalation care should be taken, by not holding the cap too close over the mouth and nose to avoid exciting struggling, or holding the breath. If struggling or holding the breath do occur, great care is necessary to avoid an overdose during the deep inspirations which follow. When quiet breathing is ensured, as the patient begins to go over, there is no reason why the inhaler should not be applied close to the face, and all that is then necessary is to watch the cornea, and to see that respiration is not interfered with.

6. In children, crying ensures free admission of chloroform into the lung, but, as struggling and holding the breath can scarcely be avoided, and one or two whiffs of chloroform may be sufficient to produce complete insensibility, they should always be allowed to inhale a little freely as during the first deep inspirations which follow. In any struggling person, but especially in children, it is essential to remove the inhaler after the first or second deep inspiration, as enough chloroform may have been inhaled to produce deep anaesthesia, and this may only appear, or may deepen, after the chloroform is stopped. Struggling is best avoided in adults by making them blow out hard after each inspiration during the inhalation.

7. The patient is, as a rule, anaesthetised and ready for the operation to be commenced when unconscious winking is no longer produced by touching the surface of the eye with the tip of the finger. The anaesthetist should never, under any circumstances, be pushed till the respiration stops, but when once the cornea is insensitive, the patient should be kept gently under by occasional inhalations, and not be allowed to come out and renew the stage of struggling and resistance.

8. As a rule, no operation should be commenced until the patient is fully under the influence of the anaesthetic, so as to avoid all chance of death from surgical shock or fright.

9. The administrator should be guided as to the effect entirely by the respiration. His only object, while producing anaesthesia, is to see that the respiration is not interfered with.

10. If possible, the patient's chest and abdomen should be exposed during chloroform inhalation, so that the respiratory movements can be seen by the administrator. If anything interferes with the respiration

By Chloroform—Continued.

in any way, however slightly, even if this occurs at the very commencement of the administration, if breath is held or if there is stertor, the inhalation should be stopped until the breathing is natural again. This may sometimes create delay and inconvenience with inexperienced administrators, but experience will make any administrator so familiar with the respiratory functions under chloroform that he will in a short time know almost by intuition whether anything is going wrong, and be able to put it right without delay, before any danger arises.

11. If the breathing becomes embarrassed, the lower jaw should be pulled, or pushed from behind the angles, forward, so that the lower teeth protrude in front of the upper. This raises the epiglottis, and frees the larynx. At the same time, it is well to assist the respiration artificially until the embarrassment passes off.

12. If by any accident the respiration stops, artificial respiration should be commenced at once while an assistant lowers the head and draws forward the tongue with catch-forceps, by Howard's method, assisted by compression and relaxation of the thoracic walls. Artificial respiration should be continued until there is no doubt whatever that natural respiration is completely re-established.

13. A small dose of Morphia may be injected subcutaneously before chloroform inhalation as it helps to keep the patient in a state of anaesthesia in prolonged operations. There is nothing to show that Atropine does any good in connection with the administration of chloroform, and it may do a very great deal of harm.

14. Alcohol may be given with advantage before operations under chloroform, provided it does not cause excitement, and merely has the effect of giving the patient confidence and steadying the circulation.

Several valuable additions have been recently made to our means of dealing with chloroform narcosis. The hypodermic injection of $\frac{1}{2}$ gr. Sparteine alone or with a little morphia, 15 to 30 minutes before anaesthesia, keeps up the blood pressure during the deepest narcosis, and certainly minimises, if it does not prevent, risk. (Strychnine may act in a similar way, and it is preferable to sparteine if heart failure threatens.) Rosenberg maintains that the lethal action of chloroform is due to reflex irritation originating in the mucous membrane, and he therefore sprays the nose with cocaine solution before anaesthesia by chloroform, and claims that he thus prevents the risk of cardiac failure. Where death has apparently taken place Liedham-Green has shown that restoration may be effected by the König-Mass method. This has succeeded when artificial respiration and all other methods have failed. It is performed by placing the ball of the thumb of the operator's right (open) hand upon the patient's chest between the apex beat region and the sternum, and pressing rapidly (120 per minute) the thoracic wall with considerable force, so as to cause direct pressure upon the cardiac muscle. Laborde's method of forcibly pulling forward the tongue and keeping up rhythmical traction upon it at the rate of 15 or 20 per minute is a most valuable procedure, and has succeeded recently in many hopeless cases.

Alexandri has drawn attention to the danger of prolonged administration of chloroform to patients suffering from renal disease.

Hare draws attention to the importance of the posture of the patient's head when serious symptoms supervene during chloroform narcosis. If the head be not in the right position artificial respiration is impossible.

By Chloroform Continued.

He insists that the head *should be extended and simultaneously moved forward*. If this be done the tongue and epiglottis are raised, and the palate caused to permit free breathing by nose and mouth.

Cocaine.

After the stomach-pump or emetics, fill the stomach with hot strong Coffee and a little Alcohol, and give $\frac{v}{ss}$ gr. Strychnine.

Coal Gas.—See Carbonic Oxide.**Colchicum.**

Stomach-pump or emetics, mucilaginous drinks, Albumin or strong Tea or Tannin, should be given, and these should be followed by a purgative, after which free stimulation may be required, and symptoms met as they arise.

Conium.

The stomach-pump or emetics, Tannin, and Castor Oil should be used. Stimulate freely by Ammonia. Hypodermics of Strychnine or Atropine may be tried, and artificial respiration persevered with.

Copper Salts.

The stomach-pump or emetics must be resorted to if free vomiting has not occurred; yellow Prussiate of Potassium, egg Albumin and Milk which form insoluble Copper Salts, are to be given; mucilaginous drinks and wheaten flour or water in which yolks of eggs are suspended, and the free use of Opium to allay irritation, are called for.

Corrosive Sublimate.—See Mercury.**Creosote. —The same treatment as for Carbolic Acid****Croton Oil.**

The general treatment for irritant poisons may be used, viz., — Emetics, or, if in the early stage, the gentle use of the stomach pump, demulcent drinks, soothing enemata, and Opium. Free stimulation and counter-irritation may be necessary.

Cyanide of Potassium

Poisoning is to be treated as if Hydrocyanic Acid had been swallowed and, if seen at once give Solution of Ferric Sulph., and use the alternate hot and cold douche, whilst Atropine is given by hypodermic injection. Whilst the poison is in the stomach Permanganate of Potassium may be given. Antal has proved that Cobaltum Nitricum Oxidation has properties powerfully antidotal to the cyanides. A solution of this salt should be given by the mouth if the poison is in the stomach, and if absorption has taken place he injects from 3 dra. to 1 oz. of a half per cent solution subcutaneously.

Digitalis.

The stomach-pump or emetics, especially Sulphate of Zinc, $\frac{j}{ss}$ drachm. or 10 minims of Apomorphine Solution hypodermically, Tannin, or animal

By Digitalis—Continued

Charcoal, free stimulation, and the hypodermic injection of $\frac{1}{16}$ gr. Aconitine, and the free use of Opium, are required. Muscarin ($\frac{1}{4}$ gr.) is antagonistic, and Alcohol should be given. The patient should be kept absolutely quiet, and in the horizontal position.

Elaterium.

Emetics or the stomach-pump must be used. Demulcent drinks and Opium are to be administered freely, and the general treatment of the symptoms of gastro-intestinal irritation is to be followed.

Eserine, or Calabar Bean.

Emetics or the pump, with Tannin or any Tannin-containing liquid, may be employed, but hypodermic injections of Atropine ($\frac{1}{16}$ gr.), till the pupils widely dilate, afford the best chance. Strychnine and Chloral have been recommended.

Artificial respiration should be assiduously tried, with friction and warmth externally.

Ether (Inhalation).

Pull forward the tongue, give free current of air, commence artificial respiration, and try the Konig-Maas method, and treat as if Chloroform poisoning.

Formalin.

Ammonia is decidedly antidotal. Formaldehyde is changed into the comparatively harmless urotropine upon the addition of free ammonia. The best method to pursue in poisoning is to give small doses of ammonia largely diluted with water, or large quantities of Mindererus Spirit, *i.e.*, the liquor ammon. acetatis every half-hour.

Fungi, or Muscarin.

Emetics or the pump should be used, and Atropine given hypodermically ($\frac{1}{16}$ gr.), and repeated till the pupils dilate, or Digitalis, or Morphine, may be given. Free stimulation, sinapisms, and friction may be required.

The writer has had to treat a large charity school of children who had eaten fungi. Many were very bad, and about six of them appeared to be dying when first seen. Atropine appeared to act like magic, and all made a good recovery.

Gelsemium.

The stomach-pump and emetics are to be used, and Bicarbonate of Potassium and Tannin freely given, warmth, free stimulation with Alcohol, electricity, and artificial respiration are to be kept up.

Hypodermics of Ammonia or Atropine, or Digitalis, are partially antagonistic. The best result will follow 3 minima of Atropine Solution.

Hydrocyanic (or Prussic) Acid.

Antidote and treatment are described under Acid Prussic.

Hyoscyamus. —Same as for Atropine.

By Iodine.

Emetics or the *cautious* use of the rubber tube of the stomach-pump should be employed, together with the free administration of starch or rye root, bread, boiled potatoes, or flour, lime water, and demulcent drinks.

Iodoform.

Emetics or the stomach-pump, and large diluted doses of Bicarbonate of Soda, followed by free stimulation and a hot pack. Saline solution injected hypodermically in large doses is recommended by Kocher.

Laburnum.

The stomach-pump, if possible, should be always used, even if vomiting has occurred, as portions of seeds, &c., may remain in the stomach. Free stimulation, and, in bad cases, hypodermic injection of Ammonia. Counter-irritation, friction, and the cold douche are necessary.

Lead Salts.

The stomach-pump, or preferably, a large emetic of Sulphate of Zinc, which is also an antidote, should be given, and followed by milk, white egg, diluted Sulphuric Acid, Epsom or Glauber's Salts, or Phosphate of Sodium, Sulphuretted Hydrogen, or Harrogate water. Demulcent drinks with mild Opium to allay pain and spasm, may be administered. (See also under Plumbism.)

Lime.

Carbonic Acid—any Aerated water, as soda water or lemonade—is very useful, or weak Acetic Acid or Vinegar, freely diluted, and followed by Oil or demulcent drinks, may be swallowed.

Lobelia and Tobacco.

Emetics or the pump should be employed, as should also Tannin, and free stimulation externally by sinapisms, friction, and dry heat, internally or hypodermically by Alcohol, Ammonia and Ether, with Styracine (25 gr.), and small doses of Opium. The patient must be kept strictly in the horizontal position.

Mercury (Corrosive Sublimate).

Emetics, or the very cautious use of the pump will be required. (The pump should not be used except in the very early stages of the poisoning.) Albumin, or Gluten (prepared by washing flour in a muslin bag), demulcent drinks, milk, and oil are to be given by the mouth, and Morphine and Alcohol subcutaneously.

Morphine.—See Opium.**Muscardin (or Mushrooms).**

Same treatment as in poisoning by Fungi—viz, the subcutaneous administration of Atropine after the use of an emetic or the pump.

Nitric Acid.—See under Acids, Mineral.

Nitro-Benzole.

The stomach-pump should be used, and a stream of warm water passed through it. Alcohol and fats must not be used—the main reliance being used upon counter-irritation by Mustard, artificial respiration, and Cyanism, and measures useful in Prussic Acid poisoning.

ix Vomica.—See Strychnine.**Mum (or Morphine).**

The stomach-pump, or, in its absence, emetics (if capable of swallowing), may be resorted to, or $\frac{1}{2}$ gr. of Apomorphine injected hypodermically. The stomach should be washed out with tepid water, and filled with strong tea, or any infusion or liquid containing Tannin. Owing to the fact that the mucous membrane of the stomach continues to excrete the poison, it has been advocated that it is of the greatest importance in all these cases that the stomach be repeatedly washed out at short intervals during the treatment.

Potassium Permanganate of Potash has been demonstrated by Moor to be a chemical antidote to morphine, weight for weight, and as it can do no harm it should be given immediately without waiting for vomiting (1 gr. in 2 oz. water). Moor argues that it should be also given after the poison has passed out of the stomach as it is excreted again by the mucous membrane later on, and advises that the stomach should be repeatedly washed out with the solution. Brier, as the result of much experimentation, has, however, proved that no excretion takes place except in infinitesimal quantity, and hence the repeated washings out are valueless. There cannot, however, be any doubt about the great value of washing out the stomach by a solution of the drug at first.

Caffeine, Atropine, or Strychnine hypodermically is to be administered. The latter should be repeated frequently as long as there are dangerous cardiac or respiratory symptoms; $\frac{1}{16}$ grain may be given every 2 or 3 hours. Ice-caps, cold and hot affusions alternately, electricity, extensive epistaxis, or very hot water, to cause vesication in desperate cases must be employed to rouse the patient, and when once roused he should never be allowed to fall asleep again, but should be kept continually on the move. Every care must be exercised lest this should be carried too far so as to induce exhaustion, as is, unfortunately, often done. Artificial respiration may be required. The dose of Atropine should not exceed 24 minims of the liquor, and should not be repeated. A larger dose only reinforces the action of the morphia.

Salic Acid.

The pump or emetics must be used. Lime (lime water, putty of lime, chalk) is the best antidote; one good dose of Castor Oil, counter-irritation, free stimulation, and the treatment for gastro-enteric inflammation should be followed.

Phosphorus.

The pump or emetics will be necessary. Sulphate of Copper, 5 grains every 15 minutes, is both antidote and emetic. Potassium Permanganate of Potassium, 1 gr. in 1 oz. water, will act as an efficient antidote or Peroxide of Hydrogen. French Oil of Turpentine or any good Oil of Turpentine, emetics, and demulcent drinks containing Magnesia and Albumin should be swallowed. Oils and butter should be avoided.

By Pilocarpine.

The stomach-pump or emetics will be required, together with the administration of Tannin and the hypodermic use of its antagonist—Atropine—in $\frac{1}{10}$ to $\frac{1}{20}$ gr doses.

Physostigma.—See under Eserine.

Potash, Caustic.

Emetics must be administered. The pump should *not* be used. Weak Acids (Vegetable preferred, and largely diluted), Oils, and butter may be freely administered. The after-treatment will consist in rectal feeding and, after the danger of perforation has passed away, the free use of barley water, linseed tea, and other demulcents.

Potassium Chlorate.

The pump or emetics and profuse demulcent drinks and purgatives are indicated, along with hot blanket baths and the treatment for Acute Bright's Disease (page 85).

Silver Nitrate (or Lunar Caustic).

Large doses of common Salt or Sea Water should be swallowed. Emetics and the pump (India-rubber tube) should be used, and white egg injected into the stomach after the poison is removed. Yolk of egg, wheaten flour, or milk mixed with water should be freely administered.

Soda, Caustic.

Acids and Oils will be required (as for Potash).

Stramonium.

Emetics, Tannin, free stimulation, and hypodermic use of Morphine are the necessary treatment (same as for Atropine and Belladonna).

Strychnine.

The pump or emetics, especially a hypodermic injection of $\frac{1}{10}$ gr Apomorphine, must be given, followed by Charcoal or Tannin in large quantities. Tobacco by rectum (with great caution—not more than 20 grains at once), Bromide of Potassium in large doses (2 drs. to 2 oz), Chloral, Chloroform, Calabar Bean, Conium, Morphine, Ether, &c., are recommended. The writer has found by experience that poisonous doses of Alcohol afford the best treatment, given both by mouth and rectum. Artificial respiration may be tried. Chloroform inhalation may be kept up as long as the convulsions are severe. Permanganate of Potassium, given immediately after a poisonous dose, would probably act as an antidote.

Sugar of Lead.

Sulphate of Zinc, Albumin, &c. (See Lead.)

Sulphurets and Sulphuretted Hydrogen.

Inhalation of air containing a small percentage of Chlorine in it, and the free administration of a very weak solution of Chlorinated Lime or Soda, constitute the necessary treatment.

By Sulphuric Acid.—See under Acids, Mineral.

Tartar Emetic.

Tannin, Green Tea, &c. (See Antimony.)

Tobacco.

Emetics, Tannin, free stimulation, and hypodermic injection of Strychnine ($\frac{1}{4}$ grain) are indicated, and the recumbent position must be strictly maintained (as for Lobelia).

Veratrine.

The pump or emetics must be used, followed by Alcohol, Opium, &c. (as for Aconite, which see).

Zinc Salts (chiefly the Chloride, as Burnett's Fluid).

The rubber tube of the stomach-pump should be used with caution, or emetics, especially Apomorphine, $\frac{1}{4}$ grain, may be injected hypodermically. Egg Albumin, Tea, Tannin, Milk, Alkalies or their Carbonates, demulcent drinks, and soothing enemata containing a little Laudanum, are to be administered.

POLYPI.

The treatment of these growths projecting from the various mucous surfaces of the body belongs to the province of the surgeon. Their removal may be effected in various ways. When the tumour is pedunculated, and the pedicle can be grasped by a stout pair of forceps, and by torsion, avulsion, ligature, or section by means of the knife, scissors, écraseur, or cautery, the growth may be safely removed. In the case of nasal polypi, if a cold wire-loop snare can be got round the pedicle or base of the growth by passing the snare along the floor of the nostril and adjusting the noose, there will be little difficulty in removing the polypus. More frequently, however, the part of the polypus which can be distinctly seen must be grasped by a fine pair of dressing forceps, and torn forcibly away from its attachments because the snare cannot be got round its base or pedicle by any artifice. In the firm, tough, or fibrous polypi springing from the roof of the nasal cavity, or from the bony prominences of the naso-pharynx, the best method of treatment is to use the wire of the galvano-cautery, and it may be often necessary to enlarge the opening of the nares to get thoroughly at the growth. Sometimes removal can be managed from the pharynx. The snare with pianoforte wire is always to be preferred to the avulsion with forceps when possible, and when followed by the sparing use of Chromic Acid it appears upon the whole to be the best method of removing polypi from the nasal cavities.

Buracz reaches polypi through the nose which cannot be removed by the forceps. After applying Cocaine to the nose and lips he makes an incision through the lip immediately to one side of the middle line, and carries it up through the fleshy part of the nose

on one side of the septum as far as the nasal bones. If the growth be very large he cuts the nasal bone and turns it aside with the flap of the skin, which, upon being forcibly retracted, permits of the nasal aperture being somewhat enlarged by bone forceps. Upon introducing one finger into the nostril and another behind the soft palate, the polypus can be easily enucleated by the finger-nail. He states that by this plan of operating, the entire nasal cavity, as far as the base of the skull, can be reached as effectually as in the more formidable operation of Laugenbeck. There is little hemorrhage, and upon bringing the edges of the wound accurately together, only a linear scar remains.

The medical treatment of nasal polypi is generally unsatisfactory but occasionally a soft gelatiniform polypus springing from the turbinated bone may be caused to shrivel up and disintegrate by the continual use of a snuff consisting of finely-powdered Tanna Acid. Parker has employed Salicylic Acid with advantage in the same way, and powdered Sulphate of Zinc or Alum is sometimes successful. The spray of strong Alcohol may be used, or various astringent solutions may be applied with a large camel's hair brush, or the same solutions may be injected by the hypodermic needle into the growth, or, in more dilute solution, they may be used as nasal douches. Glycerin of Carbolic Acid and Solution of Perchloride of Iron may be thus used. Ethylate of Sodium Solution may be efficacious if brushed over soft or even moderately fibrous polypi. Chromic Acid fused upon a roughened probe is the best of all agents for touching small polypi.

Though these methods of dealing with nasal polypi must be considered as anything but satisfactory in the first instance especially where the growths are within easy reach of the snare or polypus, nevertheless they are of great value as auxiliaries to the surgical measures.

Thus, where clusters of soft polypi hang from the interior of the nasal walls, the surgeon must often desist before he can feel confident that he has been able to seize and tear off all of them. Some will only be partially removed, and, owing to the hemorrhage frequent sittings become necessary. Then, again, the pedicles may sprout up or the growths show a tendency to return. To prevent this, Lennox Browne insists on the complete cure of the catarrh which is constantly associated with the polypoid growth. He advocates repeated applications of electro-cautery at intervals of about a week. He has given up the use of nasal douches and sprays in such cases.

Cocaine in all these performances is of the greatest value. Post-nasal growths are easily removed by the ring-shaped curette of Hartman. (See under Adenoids.)

In the case of *uterine* polypi, the ligature, torsion, snare, écraseur, galvano-cautery wire, or excision by knife, may be selected, according to the peculiar conditions maintaining in each

case. Small polypi can generally be easily twisted off by grasping the pedicle in a pair of stout ovum forceps. When large, firm polypi grow from the ceiling of the uterus, rough or strong traction upon their pedicles, especially if these are short, may cause a portion of the uterus to become inverted, and this might be included in the *écraseur* if the surgeon was not upon his guard. This once almost occurred with the writer in removing a very large sessile polypus with the chain *écraseur*.

Where the polypus is sessile, and there is much danger of hæmorrhage the wire of the galvano-cautery affords the safest and most efficient means of removing the growth.

In the case of large intra-uterine polypi, after cutting through the pedicle, the detached growth may refuse to be dragged through the cervix, as occurred to the writer in the case referred to. In this event the tumour itself may be caught in the middle by the *écraseur* and divided, or the cervix may be dilated by Barnes's bags.

Both these measures may be necessary in the first instance in order to reach the pedicle, and, if so, the method of rapid dilatation of the cervix by means of metal dilators is to be preferred.

The strictest antiseptic precautions before and after the operation should be maintained, and the vagina and uterus should be first freely swabbed with a mop soaked in equal parts of Tincture of Iodine and Glycerin, and afterwards washed twice a day, or oftener, with Solution of Boracic Acid.

POLYURIA—See Diabetes Insipidus (Page 198).

POST-PARTUM HÆMORRHAGE—See Page 361.

POTT'S CURVATURE—See Curves of Spine (Page 130).

PREGNANCY, Disorders of.

The most common departure, and the one most frequently calling for therapeutic interference, is morning sickness. As a rule, when this is but slight and does not tell upon the patient's condition, the less drugging the better. The bowels should be kept free, and this may be in most instances accomplished by attention to diet or by moderate doses of Cascara, Castor Oil, or enemata of tepid water without soap. The diet should be such as is most speedily digested, and, though a dry dietary generally does best, some cases can only get on upon food which is liquid—as strong beef tea, champagne, iced coffee, koumiss, &c. The horizontal position in bed, maintained for several hours after the morning meal often checks the vomiting.

Of drugs and methods of treatment there is practically no end, and, as the plan which appears in one case to act as a charm may in the next prove useless the physician will find himself driven to try one remedy after another till he finds the most efficient, or

till, as often happens, the vomiting stops spontaneously in spite of his exertions, for it cannot be denied that his exertions sometimes perpetuate the misery. It is therefore advisable to have a ready remedy which is perfectly harmless, and the following simple combination will be found of value in a surprisingly large number of mild cases:—

R *Acid. Hydrochlor. Dil.* ℥iv.
 Infus. Gentiana Co. ℥viiss. *misce.*

Fiat mistura. Capiat cochleare unum magnum ter in die ex paululo aqua

It may be given before or after meals as the experience of the patient decides, and Calumba may be substituted for the Gentiana.

Tincture of Nux Vomica, in 5 to 10 minim doses, appears to act much in the same way as the above, and Quinine occasionally proves useful also. Hydrocyanic Acid, in doses of 2 minims, may be given alone or mixed with either of these formulæ, or it may be given with the following.

Bismuth is a harmless drug, and sometimes proves efficient. It may be given with the previously-mentioned substance or in combination with the following.

Pepsin is sometimes efficacious, and where it fails in preventing vomiting, it may do good by hastening digestion so that the patient derives more benefit from the food before it is rejected.

Ingluvin—a powder prepared from the gizzard of the common fowl—acts like Pepsin, but is more frequently efficacious than the drug. It may be given in 10 grain doses every 4 or 6 hours commencing before the patient leaves her bed for the day.

A favourite combination consists of several of the foregoing remedies. It is often efficacious in relieving the vomiting of gastric ulcer and dyspepsia, but often fails completely in pregnancy.

R. *Acid. Hydrocyanici Dil.* ℥i.
 Liquor. Morphinæ Hydrochlor ℥iiss.
 Liquor. Bismuthi (Schacht) ℥iiss.
 Vini Pepsinæ ad ℥iv. *misce.*

Fiat mistura. Capiat ℥i. ter quaterve in die ex paululo aqua post cib. p. p. a.

Morphia has met with some favour, especially when given as a suppository by the rectum or vagina, though the writer has found far better results from administering the minute pearls, each containing $\frac{1}{2}$ grain, by the mouth. Sometimes it proves effectual when given hypodermically.

Oxalate of Cerium has long maintained the reputation of being a specific in the condition under consideration, but the writer has been so uniformly disappointed with it that he seldom now uses it unless when most other remedies fail, and he finds then that it fails also. 3 or 4 or even 8 grains may be given as a powder.

Carbolic Acid is sometimes useful, but Creosote is much better, and may be given in the form of capsule.

Salol in 2 grain doses acts in the same way, and Menthol has its advocates.

Cocaine has been highly praised, but the earlier reports were too roscate. $\frac{1}{4}$ grain in solution may be given every two or three hours, and sometimes it acts most rapidly and effectively. 1 to 2 grains are sometimes given.

Antipyrine and Antifebrin have been recommended, but it is very doubtful if they exert any beneficial action.

Paraldehyde in minute doses has been tried successfully in a limited number of cases. 3 to 5 minims may be given every hour in syrup.

Chloral Hydrate is praised, but it must be used with caution. Its best results have been obtained when given with the following.

Bromide of Potassium is very valuable, but it must be given in large doses, and these sometimes increase the irritability of the stomach and are rejected. Hence the best method of giving the drug a fair trial is to give it in the form of an enema, combined with Chloral. Guéniot uses 30 grains of Bromide of Sodium and 30 grs. of Chloral in 9 ounces of milk and water as a rectal injection. Weiss reports success after rectal injections of 3 to 4 pints of 2½ per cent. Saline solution.

The following combination of some of the previously-mentioned drugs may fairly have a trial in a bad case:—

R. Cocainæ Hydrochlor. gr. vi.
 Phenazoni 3iss.
 Potassu Bromidi 3v.
 Infus. Gentianæ Co. ʒviij. misce.

Fiat mistura. Capiat cochleare mag. ter in die ex paululo aque ante cibos.

The following has proved useful in a bad case of the writer's:—Cocaine, $\frac{1}{8}$ gr.; Bismuth Carbonate, 10 grs.; Morphine, $\frac{1}{2}$ gr.; Papain, 1 gr., in powder; one to be taken every 2 to 4 hours.

Aconite, given to the extent of producing its physiological effects, has been found by Wood to be often advantageous, though few will care to push a remedy of such potency so far.

Liquor Potassæ, alone or combined, with Morphia, has sometimes given good results. Not more than 10 or 15 minims should be given, and the dose should be freely diluted.

Calomel has been tried in small doses frequently repeated in an attempt to produce salivation, but the practice is not to be recommended.

Tincture of Iodine, Fowler's Solution, and Ipecacuanha Wine have each been extolled, in doses of 1 minim diluted with water. Their effects are even more uncertain than most of the previously mentioned drugs. Tannin in 3 grain doses has occasionally proved useful.

When, however, in spite of all drugs, the vomiting continues so as to seriously weaken the patient, and emaciation with thirst, a hot skin, and red tongue show themselves, the situation becomes serious, and feeding by the bowel must be commenced and steadily adhered to. Ice or Ether spray to the epigastrium or sinapisms, if not before tried, should be applied, and the patient rigidly confined to the horizontal position in bed.

Sometimes the vomiting is speedily stopped by a blister applied over the first three dorsal spines. Should the weakness and emaciation proceed, the physician may ultimately have to induce premature labour, but before doing so various attempts may be made in order to counteract or correct any source of irritation which possibly may exist in the region of the uterus, ovaries, or vagina. Thus, flexions of the uterus have been proved to be a cause in some cases, and relief has been said to immediately follow the adjustment of a properly-fitting pessary.

Erosions, ulcerations, lacerations, or other abnormal conditions of the os or cervix may be the exciting cause, and these may be treated by caustics, leeching, or suitable operations or applications. Cocaine in strong solution or in ointment, applied directly to the os, has stopped the vomiting in some cases, and a cotton-wool tampon saturated in Glycerin has, by relieving congestion, removed the sympathetic vomiting. The routine plan of applying strong Nitrate of Silver is to be condemned, but it may have a trial in severe cases before resorting to more serious measures. Routh applies cotton-wool saturated in a strong Iodine solution to the os, and Iodized Phenol may be brushed over the os and cervix without risk.

Electricity has undoubtedly proved efficacious in several cases, and if used with proper precautions is not at all likely to induce abortion. The positive pole is placed in contact with the os or cervix, whilst the negative is applied over the lower dorsal vertebrae, and a continuous current, registering from two and a half to five milliamperes, may be used for seven to ten minutes. Günther, who recommends this treatment, points out the danger of producing abortion if the current be interrupted, and he urges the necessity for avoiding this.

Copeman's plan may be tried before inducing labour. He recommends, and his practice has been successfully carried out by others, that the os should be dilated along with the lower portion of the cervical canal.

When all measures have failed to stop the vomiting, and when

nutrient enemata have been unable to prevent marasmus, the last resource, after consultation with another physician, should be undertaken, and the uterus should be emptied by procuring abortion, or by inducing premature labour. It is, however, needless to say that this procedure will be rarely called for, even by those extensively engaged in obstetric work.

The various other disorders of pregnancy are to be treated upon general principles, and need not be referred to here. Abortion has been dealt with under its appropriate heading, and Albuminuria may be treated upon the lines laid down under its own heading or under Bright's Disease. Eclampsia will be dealt with under Puerperal Convulsions.

PRESBYOPIA.

The treatment of this condition can only be carried out by the use of the proper convex glasses, which will enable the patient to read with comfort at about 10 or 12 inches. It is a mistake to order strong lenses at first, and as the patient gets older the convexity of his glasses may be increased till he reads with comfort at 9 inches. It may be necessary to correct both eyes for the same distance, and many patients prefer to use stronger glasses when working by artificial light.

PRICKLY HEAT.

Or *Miliaria Rubra*, demands attention in the first place to the clothing. The best form for wear is undoubtedly fine openly-woven woollen, or a mixture of wool and silk; linen and cotton are objectionable, especially linen, next to the skin. Excessive exercise and alcoholic beverages are to be prohibited. Where the attack is very severe the patient should be advised to do his active work in the early morning or evening, and rest in the shade during the hot hours. If a higher altitude is available the change is speedily beneficial, and in bad cases a removal to a cooler climate may be essential. Too much soap and bathing are injurious, and theunction of the body with any pure animal fat every morning is a valuable prophylactic. Lotions such as are suitable in eczema have been recommended, as Goulard Lotion with 2-5 per cent. *Liquor Carbonis*, but the best results will be obtained by carefully dusting over the affected regions with a finely prepared Fuller's Earth mixed with 20 per cent. Boric Acid and 20 per cent. Zinc Oxide.

PROCTITIS.

Inflammation of the rectum is to be treated upon the same lines as are indicated in the treatment of other inflammations. The cause should be sought for and treated or removed when present, and fissures, piles, fistulae, ulcers, gonorrhoeal pus, worms, or foreign bodies should be dealt with before permanent relief can be expected. More difficult are the cases of which the writer has

chanced to see several) where the proctitis is caused by the discharge of pus from old abscesses or sinuses in the pelvis or in connection with disease of the vertebrae or pelvic bones.

Warm poultices, hot fomentations, or hot sitz baths may be tried at first, after which, or whilst sitting in the bath, the rectum may be irrigated by a stream of warm water. If arrangement is made for the return of the water, the injection can be carried out for considerable periods without dilating the inflamed bowel or exciting spasm in the sphincter. Iced water injections may be thus applied, and at a later stage antiseptic solutions, as Boracic Acid, and, at later stages still, astringent injections may be thrown into the bowel.

Under a previous heading the writer has pointed out the great value of Conium (see page 53) as a rectal sedative, and the B.P. ointment of this drug is of the greatest benefit.

In very painful cases the Juice of Conium may be evaporated for a short period at low heat, to expel any spirit contained in it, and 2 drachms, or what would correspond to this amount of the fresh juice, may be injected with good result.

Under Anus, Fissure of, page 52, the list of local sedatives has been discussed, and need not here be repeated.

Where the pain and tenesmus are caused by the passage through the rectum of irritating discharges, the writer has used the following injection successfully with the view of shielding the inflamed membrane from irritation :—

R. *Bismuthi Carbonatis* ℥vj.
 Vitellum Ori
 Olei Olivæ ℥iiss.
 Acidi Carbonici gr. xxx.
 Hazelin ad ℥viij. misce.

Fiat injectio. Signa—"Half an ounce to be injected by a glycerin-syringe into the rectum when required."

PROGRESSIVE MUSCULAR ATROPHY—See Paralysis (Page 667).

PROLAPSUS ANI et RECTI.

The first thing to be done is to effect the return of the prolapsed anus or rectum. This is generally an easy matter, and by gentle pressure with the surgeon's fingers the mass is slowly pushed back till beyond the reach of the sphincter, or the fingers of the patient's own hand, crowded together at their tips so as to form a cone, may be steadily pressed against the prolapse till it disappears.

In the case of children there may be more difficulty, and some pressure may be needed to press out the blood from the prolapsed bowel, and, to overcome the resistance and struggling of the patient, he may be placed across the lap of the nurse, and his head depressed almost to the ground. A speedy method is to oil the right forefinger, and pass it into the bowel and press it upwards as if making a rectal examination, and the prolapsed mass generally speedily retreats.

A small pad of dry lint being placed over the anus, the nates may be strapped together by broad strips of adhesive plaster or a binder may be applied to the pelvis.

Cripps effects reduction in bad cases by wrapping a piece of lint round the index finger, and then inserting it into the protruded canal of the gut. As the finger is pushed upwards, the lint, being dry, sticks to the mucous surface and assists reduction. After this has been effected the finger, which had been previously well oiled, is slipped out, leaving the lint temporarily within the bowel.

Hajeck introduces ice tampoons. A conical piece of ice is tightly surrounded by iodoform gauze and pushed into the centre of the prolapse, which is thus easily reduced, the ice and gauze following the protruded mass into the rectum, and being left *in situ*. The process is repeated after each act of defecation. Prolapse becomes less and less frequent, and permanent cure has, he says, always followed even in the worst cases.

A warm injection of about 8 oz. water before the bowels are moved, the passage of the motion whilst the patient is as far as possible upon his side, and the injection of a very small quantity of very cold water afterwards, was Brodie's method of dealing with all mild cases.

The cause of the prolapse should be carefully investigated and remedied. This may depend upon such a number of abnormal conditions that the physician should explore the pelvic region with care. The most common cause in adults of prolapse of the anus or lower part of the rectum is hæmorrhoidal growths, and, as already stated, when these are present the patient should be educated and warned to be certain to return the prolapsed mass after each evacuation. When the condition of the part warrants an operation for the piles the prolapse is effectually cured by their removal. As a palliative remedy cold sponging, bathing, or cold water injections are most valuable in this as in most cases of prolapse. Worms when found should be expelled by injections of a large tea-spoonful of common salt, dissolved in half a tumblerful of water.

Stricture of the urethra or rectum, enlarged prostate, a calculus in the bladder, or a polypus in the rectum or bladder, may be the cause, and the surgical procedures necessary to remove these causes will generally cure the prolapse.

In the case of children many authorities are convinced that

improved hygiene may do much. Where there is marked emaciation, if this can be remedied the prolapse disappears, hence the necessity for good feeding and such agents as Cod Liver Oil. Cripps lays stress upon the importance of restoring the cushion of fat in the ischio-rectal fossæ, the absence of which, doubtless, facilitates the descent of the bowel. The importance of attending to the bowels so as to prevent straining from constipation can hardly be exaggerated. Sulphur is the best laxative for this purpose.

Small irreducible prolapses, which have existed for a considerable time, may be removed in the same way as if there were a tinged protruding internal piles. The continuous current has been used with success to restore the tone of the muscular fibres of the gut.

Drugs have been used in chronic reducible cases in order to avoid the employment of surgical measures, and they sometimes are of great value. Thus, moderately strong solution of Tannin, Krameria, or Oak Bark decoctions, injections of Alum, Sulphate and Perchloride of Iron, Hydrastis, Nitrate of Silver, and other astringents may be injected in small quantities. Ice may be likewise used, a piece as large as a plum being inserted occasionally beyond the sphincter.

Ergot has generally given much better results than any other drug. It is, however, more suitable in cases where the rectum is involved, but may be used in chronic anal cases. One, two or three grains of Ergotin should be injected, as originally suggested and carried out by Vidal, into the prolapsed bowel. Glycerin injections (2 drachms) have proved efficacious in prolapse following the diarrhoea of children.

Brushing over the prolapsed anal mass by strong Nitric Acid is a very severe and may become a serious measure, but often it is a highly efficacious method when the anus only is involved. It is perfectly safe if the acid be applied in limited amount, as in the operation of linear cauterisation.

The actual or thermo-cautery may be used with great advantage in anal and in slight rectal prolapses, the iron being lightly drawn along the prolapsed membrane in a linear fashion.

Cripps prefers this method to all others in most cases. He operates with the patient in the lithotomy position, making four lines with the actual cautery by drawing the iron along the bowel in its long axis, one in front, one behind, and one on either side. These lines begin as high up as possible, and terminate at the anal margin. They should be about $\frac{1}{2}$ inch in width, and deep enough to sear thoroughly but not to destroy the mucous membrane. Where the lines cross large veins, these should be tied on either side of the line with a Liston's needle. The bowel should be returned quickly, a strong rubber tube of $\frac{1}{4}$ inch in calibre and 7 inches long is passed into the rectum and the space between it and the mucous membrane is to be packed all round with cotton wool, dusted with Iodoform, the mucous

surface being first protected by strips of oiled lint. Flatus finds an easy exit through the tube, whilst an even pressure is kept up. The rationale of the treatment is to excite inflammation in the submucous tissue, so as to bind the mucous and muscular coats together in order to prevent the initial slipping, which is the chief cause of the affection.

Excision of portions of the prolapsed mucous membrane may be performed so as to lead to contraction after cicatrisation. Kelsey, of New York, employs a simple and ingenious method. A curved needle is introduced in the middle line, just below the junction of skin and mucous membrane, and a silk thread is carried half way round the anus and out again; the needle is again inserted and brought out at the first puncture, the little finger is now introduced into the anus, and the string tied snugly round it. A submucous support to the sphincter is thus provided which is left *in situ* for three weeks. The operation yielded most satisfactory results.

Curling recommends that in adults the anal aperture should be contracted, and the fall of the rectum prevented by the application of the Mineral Acids or by Caustic Potash applied to the mucous membrane at its juncture with the skin. This does not seem to the writer to be as likely to result in permanent relief as linear scarification or removal of strips of the mucous membrane.

In very severe cases where a considerable portion of the rectum is constantly prolapsed, the best procedure is to dissect up and remove a broad flap of mucous membrane from the surface of the prolapsed bowel, the margins of the mucous membrane are then to be brought together by sutures so as to very considerably reduce the dimensions of the bowel, a second or third flap may be dissected off at opposite aspects, and the same plan of bringing together the margins of the gap, left after dissection of the flap, is to be carried out. The operation may be followed by alarming hæmorrhage, and most careful after-treatment as for operations for extensive hæmorrhoids is requisite.

In still more serious cases circular resection of the gut may be performed, and Milkuletz has successfully resected two and a half feet of the prolapsed colon. McLeod has introduced an ingenious but heroic operation by which he fastens the upper end of the rectum to the anterior abdominal wall by a double series of silk ligatures passing through the mucous and serous coats of the bowel. Mr. Kirk has recently reported successful results from this operation.

Peters, of Toronto, employs this operation of Recto-pexy, the sutures being inserted in such a way as to narrow the dilated rectum and prevent invagination of the colon.

PROLAPSUS UTERI.

As a rule there will be no difficulty in replacing the prolapsed organ as the patient lies upon her left side or in the genu-pectoral

position, steady, gentle pressure sufficing to restore the uterus to its normal position in the pelvis. Sometimes, where *compex procidentia* exists, it may be found difficult to accomplish this without resorting to the use of considerable force, which may be justifiable under these circumstances. The patient should be kept to bed for a few days, when the rest will be found to have materially diminished the weight and size of the organ, so that steady pressure directed in the axis of the outlet, and afterwards in the axis of the body of the pelvis, effects reduction.

In mild cases prolonged rest and the frequent use of astringent injections, such as the cold saturated solution of Alum or decoction of Oak Bark, will often prove efficacious. It is a mistake to think that nothing can be done without inserting supports or resorting to surgery. Many cases, even where the organ has been long prolapsed, may be permanently cured by absolute rest for ~~some~~ weeks and the daily use of astringent lotions afterwards, together with such measures as will reduce the size and weight of the enlarged or congested organ. The bowels and bladder must be regularly relieved.

A large tampon of absorbent cotton wool, soaked in the Glycerine of Borax, and inserted into the vagina, where it may be kept for 48 hours, has a rapid action in reducing hyperæmia.

Tonic remedies, such as Iron, Quinine, and Strychnine, externally, and sea bathing, with periods of absolute rest upon a hard sofa for several hours during the day, are not without their beneficial influence.

Where the bladder or anterior wall of the vagina prolapses the patient should be instructed to pass water when resting upon her knees and elbows, and the physician should see that the daily regular use of the vaginal douche every eight hours is conducted efficiently and thoroughly. Thus a long vagina pipe should be used, and a copious stream of cold, or almost cold, water should be injected for three or four minutes, till all traces of mucus or discharge are washed away, after which a quart or more of the cold saturated Solution of Alum is injected. The continuous current is often beneficial in restoring the tone of the relaxed structures.

The pressure of tight clothing round the waist or pelvis must be avoided, and where the abdomen is very pendulous, a neatly fitting abdominal belt, constructed by a skilful corset or truss maker, may be worn with advantage. The ordinary corsets are always to be avoided.

Some patients who cannot wear pessaries manage to keep themselves comfortable by the daily introduction of plugs or tampons of cotton wool inserted into the vagina, and removed at bed time.

Where the above measures fail to give support, and the uterus continues to fall downwards, there should be an attempt made to keep the organ up by means of a pessary.

Of these the variety is endless, but the physician should aim at a selection of a support which will not destroy the remaining elasticity or contractility of the vagina, or unduly stretch the uterine ligaments. Hence the old, solid, globular boxwood pessaries could not be selected, and the same objection applies to the black boxwood ring or vulcanite ring instruments, though the latter has succeeded in keeping the uterus in position with these after failure with every other instrument. The elastic ring is then satisfactory where the vagina is very capacious, and those under instruments containing a spring embedded in the rubber are to be preferred to the weighty thick rings of pure rubber, but after all are the hollow elastic rings well filled with air. In mild cases, or where there is a good perineum, a well-fitting Hodge by far the most satisfactory form of support, and, though it often may be disappointing by slipping out, when a suitable shape and size is selected which remains *in situ* there is generally nothing more to be desired.

Greenhalgh's elastic spring with cross-bars or Galabin's vulcanite instrument may be found to succeed where Hodge fails. The former is indicated when the bladder tends to prolapse. Sometimes a large Albert Smith pessary with exaggerated curves may be found to remedy the prolapse.

Where the pericentia is complete, and the perineum useless as support, the cup and stem pessary of Barnes will generally prove satisfactory. The neck of the uterus sits or lies in the cup, and the fundus is supported from below by a waist-band and perineal straps. Should be removed at night, and after washing of the vagina it may be introduced by the patient in the morning. There are various modifications of this instrument, one of which is intended to be retained in the vagina without supports, but it generally fails. Cutter's ring pessary acts upon the same principle as the former instrument and it is retained in position by a rubber strap attached to a waist belt.

Zwanke's pessary sometimes keeps the uterus in position when all else above fails, but the writer has found that it so very often breaks and gets out of order that it would be almost necessary for the patient to permanently retain the services of an instrument maker. Blades should be inserted whilst closed, and screwed out when in the vagina. It should be taken out generally at night, and inserted before getting up in the morning. If left in position for long periods, serious ulceration may be set up.

Braun's appliance is more satisfactory. It consists of a pear-shaped soft rubber bag, which is inflated with air or water, or oil, after its introduction.

Gynecological massage and gymnastic exercises, according to Lind's method, are said to be of the greatest use in prolapse, but they require considerable experience and the help of a skilled assistant, and many authorities have found them most satisfactory.

Where the above palliative measures fail, or where, for special reasons, a more permanent or radical cure is desired, various surgical measures have been recommended and practised with varying success, the special operation being selected which, on account of the anatomical condition of the parts, appears to give the best prospects of success.

The operation of building up a new perineum where this part has been ruptured or destroyed in previous labours, is a rational procedure, and though it may fail to cure the prolapse, it generally succeeds in leaving the parts in such a condition as will enable the physician to most successfully remedy the displacement by a well-adjusted Hodge's pessary, which was not possible before. If this end can be completely gained, the physician may rest satisfied, unless the patient insists upon a more radical procedure. Sometimes, however, a new perineum cannot be made, and the number of operations which have been suggested to cause narrowing of the vaginal canal, or to produce lateral or ventrofixation, is beyond narrating in the space at our disposal.

Asch has extirpated the uterus and resected the vagina for complete prolapse. Others have been content to remove a portion of the elongated cervix, but this practice has been condemned by Emmet and others.

The operations of Simms and of Emmet, whereby a narrowing of the vagina is accomplished by the removal of flaps of mucous membrane from its anterior surface, or *posterior colporrhaphy*, which aims at the same object by removing portions of the posterior vaginal walls, may be adopted.

Pear passes a double row of sutures along each side of the vagina through the recto-vaginal septum and the vesico-vaginal septum respectively.

Simon's operation is an excellent one in some cases. He pares the surfaces of the posterior aspects of the labia majora and the neighbouring tissues at the vaginal outlet, and after bringing the surfaces together by deep and superficial sutures, the perineum is thus greatly lengthened, and the uterus imprisoned.

Phillips points out the different ways in which ventral fixation of the uterus to the anterior abdominal wall by abdominal section and suturing of the organ or its appendages may be carried out, viz. (1) By hysterectomy—removing the uterus and bringing the stump into the abdominal wound. (2) Removal of both ovaries and appendages, and suturing one or both stumps into the abdominal wound. (3) Suturing the round ligaments as they pass obliquely from the uterus, and bringing the stitches out external to the median incision. (4) Hysterorrhaphy—by passing stitches through the muscular tissue of the fundus. (5) Removal of the appendages on one side only and suturing the stump, not into the wound, but external to it, by making the stitches pierce the abdominal wall, adhesion between the stump and parietal peritoneum being the object to be attained.

Baldy states that in complete chronic prolapse the following operations must be done as a matter of routine —At the first sitting curettage, trachelorrhaphy, Emmet's anterior colporrhaphy, and hysterorrhaphy. In 3 or 4 weeks afterwards either Hegar's colpo-perineorrhaphy or Emmet's perineorrhaphy should be done.

PROSTATE, Inflammation of.

Whilst soothing remedies are being employed for the relief of the prostatitis, the cause of the attack should receive attention. Thus, sexual excess, gonorrhœa, cystitis, or an impacted calculus must be met by appropriate remedies. Absolute rest in bed, except when the patient is sitting in a sitz-bath, is essential, and the hips should be elevated above the trunk. The bowel should be cleared out by a copious warm water enema, and by a little ingenuity a stream of warm, hot, or ice-cold water may be made to irrigate the lower part of the bowel, the temperature of the water depending upon the sensations of the patient. Hot poultices or warm fomentations, or a large piece of ice occasionally introduced into the rectum, act beneficially upon the same principles.

Leeching the perineum is sometimes very successful in relieving pain, and a small cupping-glass may be applied over the bites, or warm fomentations to encourage the bleeding, may be tried.

Where there is smart urethral irritation, gleet, or gonorrhœa, the frequent injection of hot or warm water down the passage does good, but astringent or irritating injections are to be forbidden.

The occasional administration of a large Saline purgative is most beneficial, and the following mixture may be given in acute cases with benefit:—

R. *Liquor. Morphine Hydrochlor.* *℥iij.*
 Potassii Acetatis *℥iv.*
 Tinct. Hyoscyami *℥iv.*
 Vini Antimonialis *℥i.*
 Liquor. Ammonie Acetatis ad *℥iv. misce.*

Fiat mistura. Capiat ℥j post cibos quater in die ex ℥iv.
decoch hordei recentis.

Morphia, by the rectum, in the form of suppository, is always indicated for the relief of pain. Ichthiol, 10 grs in a suppository, gives excellent results. Should signs of suppuration occur, and fluctuation be distinct, the abscess may be aspirated or punctured by a sharp knife through the rectum, or a free, very deep incision may be made in the perineum with a staff in the urethra, or the left index finger being placed in the rectum, a double-edged knife may be thrust deeply into the tissues in front of it till pus is

reached. Prostatic calculi, if present, should be removed through the incision, and the wound must be daily syringed with an antiseptic solution, and drainage established, if necessary.

In chronic inflammation of the prostate, cold sitz baths, cold enemata, counter-irritation, by means of small blisters to the perineum, and the passage of a soft rubber catheter smeared over with Unguentum Conu, so as to draw off the urine when necessary, and the occasional injection of 5 to 10 minims 1 per cent. solution of Silver Nitrate into the prostatic urethra are to be employed. As the urethra becomes tolerant the strength of the injection may be gradually increased to 5 per cent. or 10 per cent. The stronger solutions should always be given when the bladder is full, so that excessive action may be neutralized by prompt urination.

Feleki and others strongly recommend prostatic massage as the only efficient treatment. This can be carried out by the finger in the rectum, or by one of the special instruments designed for the purpose. The process is repeated 2 or 3 times a week, and 6-8 sittings generally give marked relief. Internally, small doses of Boracic Acid, in conjunction with moderately large doses of Tincture of Hyoscyamus and Ergot, may be used.

Whilst attention and treatment are directed to the cause of prostatitis, where this is owing to the following condition the surgical and medical treatment to be presently detailed must be patiently carried out.

PROSTATE, Hypertrophy or Enlargement of,

Requires varied and very skilful management according to the stage of the disease and the extent of the enlargement. Cystitis and retention of urine, the former depending upon or resulting from the latter, will require constant attention.

In cases where the enlargement of the gland only leads to a small amount of urine being left in the bladder after the patient thinks he has quite emptied himself by micturition, the symptoms are considerably masked, and the surgeon may long imagine that he has only got a simple case of cystitis to treat. The decomposition of the residual urine sets up grave local and constitutional symptoms, and if not promptly and judiciously met, a fatal result too often follows.

In such cases a full diagnosis of the situation is absolutely necessary, and this is comparatively easy. The finger in the rectum will ascertain the presence of the enlarged organ, and the age, generally over 57 or 60 years, will furnish strong and almost conclusive evidence of the nature of the enlargement. If the patient is made to empty his bladder as completely as possible, the passage of a soft rubber catheter immediately afterwards will demonstrate the amount of residual urine left after micturition.

If the quantity of urine is comparatively small, amounting to under 3 or 4 ounces, the general surgical rule is that the patient should at once enter upon catheter life, and henceforth draw off

the urine once or twice or oftener every day, remembering, however, that the mischief is mainly, if not entirely caused, not by the amount of residual urine left constantly in the bladder, but by the changes which sooner or later are set up in the retained fluid. If any means could be obtained whereby these changes could be effectually prevented the patient's life need not, in mild cases, be subjected to the risks and dangers which sometimes follow the daily use of the catheter.

Harrison states his belief in the necessity of having some residual urine always in the bladder, which in this class of case has ceased to be able to become a closed space after all the urine has been withdrawn. He emphasises the opinion that the residual urine should only be withdrawn by the catheter when there is evidence that either by its quantity or its quality it is doing positive harm to the individual. He believes that the sudden and complete emptying of the bladder in these cases has everything to say to the setting up of the so-called catheter fever. The writer has seen most serious results follow the complete evacuation of the bladder in chronic cases, when first coming under observation, where the residual urine though fetid was abundant. He lays it down as a rule for himself that in such a case, when it is necessary to remove all the residual urine for diagnostic purposes, half as much Boric Solution should be injected immediately.

Until within a comparatively recent date therapeutics did not furnish any reliable and safe means for disinfecting the residual urine, and the above surgical law could not be neglected with safety.

Perez, however, found that Boracic Acid when given internally checks putrefactive changes in the urine, and the writer has found in scores of cases that a few daily doses of 10 to 15 grains of this drug very speedily alter the character of fetid urine in chronic bladder affections (see page 79). In many instances he has found that all the symptoms of bladder irritation rapidly subsided after beginning such treatment, and the high-smelling decomposed secretion which was passed on micturition gave place to a healthy and sweet secretion, and in several cases as the irritation of the bladder subsided, this organ had so recovered its tone and power that it was able to completely evacuate its contents, notwithstanding the continuance of the enlargement of the prostate. The cystitis necessitating frequent and fruitless attempts to micturate, increases considerably the prostatic trouble by grafting upon the hypertrophy a congestive or inflammatory condition of the enlarged gland. The relief is sometimes, though rarely, experienced after beginning catheterisation, which so relieves the irritability of the bladder and prostate as to enable the patient to leave off its use for a long period, and in some very exceptional cases for the remainder of his life. Unfortunately boric acid often cannot be tolerated by the stomach, and this is constantly the case where the kidneys are diseased. The writer has found that the most

reliable drug then is Creosote given in the form of capsules 2 minims, 3 or 4 times a day. Salol and many other antiseptics mentioned at page 79 may be used.

With these facts one is often justified in postponing obedience to the above law, and always in mild or recent cases the patient may safely have the benefit of the chance. Where the hypertrophy continues to advance, and the amount of residual urine increases and especially when occasional retention supervenes, there is little use in trusting to the simple procedure of rendering the urine aseptic, whilst grave structural alterations may be slowly taking place in the bladder, ureters, or kidneys, owing to the increased pressure caused by obstructed flow.

Under these circumstances catheter life must be entered upon seriously, though occasionally the patient may find that he sometimes is rewarded by such an improvement or amelioration in his symptoms as will enable him for a time, at all events, to lay the catheter aside. In advanced cases, of course, this never happens. Harrison has proved the advantages which follow persistent dilatation by means of a dilator designed for the purpose.

The best catheter for use is the soft vulcanised rubber which the bladder can be entered by it. The almost invariable advice given to lubricate and keep this free from germs by Carbolic Oil

Oil so acts upon the rubber as to render it brittle or "tearable," and it also destroys its polish. Hence it never should be employed.

For many years the writer has recommended the 50 Glycerin of Borax (made without the addition of water). This is an excellent lubricant, and preserves the rubber in good condition, and it is fatal to all germs. Before use the instrument should be placed in boiling water for a few minutes, when it may safely be regarded as aseptic.

H. T. Herring has devised a valuable appliance for the sterilisation of soft catheters, this is made by Maw & Son, and removes all difficulties and dangers as regards sepsis. It is described and figured in the *British Medical Journal*, May 25, 1901, and the writer has proved its value. It can be easily manipulated and carried about by the patient himself.

The patient should be taught to use the instrument himself at regular and stated times. The necessity for strict asepsis must be thoroughly impressed upon him, otherwise he is quite certain ere long to bring on himself all the misery associated with urethritis and cystitis. Where the rubber fails to worm its way along the urethra a plain English gum elastic catheter, without a stylet, may be used. Large sizes always should be employed. The French *coudée* is a favourite instrument, but the Belfast linen catheter is coming rapidly into favour. Harrison points out the great importance of not having an instrument of large calibre which empties the bladder too rapidly.

The bowels should be kept constantly free, constipation being always injurious. Food, exercise, and drugs are to be employed

as circumstances demand. The occasional use of Boracic Acid (10 grains every morning) and of *Cascara Sagrada* (one dose at bed-time) is often all the medicine required.

The following mixture may be used to give tone to the vesical coats, and to diminish irritability and keep the urine aseptic—

R. *Tinct. Nucis Vomicae* ℥iv.
 Acid. Boracici ℥ij.
 Tinct. Belladonnae ℥ij.
 Tinct. Hyoscyami ℥iss.
 Infus. Buchu ad ℥x, *misce.*

Fiat mistura. Capiat coch. mag. ter in die ex aq. kali effervesc. post cibos.

For the chronic cystitis of inflamed or enlarged prostate there is no combination so valuable as Santal and Saw Palmetto.

Washing out of the bladder is often indicated, but the skilful use of internal antiseptics renders it unnecessary unless under exceptional circumstances.

Under exceptional circumstances a stream of any unirritating weak antiseptic solution may be passed through the bladder by attaching a few feet of small rubber tubing to the rubber catheter (making the joint with a small piece of glass tubing). Into the free end of the tubing a small glass funnel is inserted. By this simple contrivance the bladder may be washed out by the patient himself at any time. In some cases where a catheter must be left in the bladder, the soft rubber instrument is the best, and Browne advises that a leaden stylet is perfectly safe, and it will be found to prevent doubling up of the rubber.

The great majority of cases manage to exist with very little discomfort under the conditions imposed by catheter life, but occasionally even the catheter fails to give relief, and may be passed with difficulty, and when the patient appears to be wearing out with incessant pain and calls to micturate, further surgical interference is demanded.

Thus must point in the direction of incision into the bladder and the establishment of such efficient drainage as will give the bladder absolute rest for a time by allowing the urine to flow through it as it trickles from the ureters.

Numerous operations are practised, the boldest of which is that successfully practised by McGill, Kummell, G. B. Browne, Mayo Robson, and many others. This is gaining rapidly in favour, and consists in a partial extirpation of the gland after opening the bladder above the pubes. The operation is known as McGill's Supra-pubic Prostatectomy.

After opening the bladder the projecting portion of the prostate is removed from the inside by the scoop and finger. Kummell

uses the thermo-cautery for its destruction. After a short time complete relief follows the operation, and the great majority of the cases never afterwards require the use of the catheter, the power of micturating being established for the remainder of their lifetime. Freyer and others have pointed out the ease with which the enlarged lobes can be completely enucleated with one index finger in the bladder and the other in the rectum. The complete enucleation would appear to be much less risky than the partial operation. The supra-pubic opening seldom remains open for any length of time. During the operation the inverted position of the patient should be adopted, and afterwards the bladder wound should only be partially closed by sutures. The best dressing consists in the free use of wood-wool pads.

Freyer's recent cases (*British Medical Journal*, July 20, 1902) lead to the hope that a new era in the surgery of the prostate has been opened. He operates by the supra-pubic route, and by the finger tip alone without cutting forceps or scissors he enucleates the entire enlarged prostate in its capsule, which strips off the urethra, leaving this canal untouched and uninjured. Mayo Robson, however, still maintains that this is impossible.

Whitehead establishes a permanent perineal opening after a median perineal urethrotomy. Through this a drainage tube may be worn or a catheter passed. McGuire establishes a permanent supra-pubic urethra. A permanent supra-pubic fistula and the constant use of a drainage tube may be tried. The various methods of tapping the bladder by the rectum are not to be recommended, nor is perineal cystotomy to be advocated.

The various methods of removing portions of the enlarged gland through the perineum appear to afford fewer advantages than McCall's plan, and they will probably continue to be employed only under special circumstances.

Section of the vas and ligature of the internal iliac artery have been advocated.

White's operation, or castration, has now had a sufficiently extensive trial to enable surgeons to form a fairly reliable estimate of its value. Like many other methods of treatment, its first brilliant promises have hardly been fulfilled, but it has established a position in surgical practice likely to be maintained. The relief derived from the proceeding is sometimes surprising, and follows operation with unexpected rapidity; but unfortunately a more extensive trial has shown that about 20-25 per cent. of cases derive no benefit from the operation, while in a number of others the relief is only temporary. The mortality would appear to be about 10 per cent., and subsequent mental symptoms have developed in a small proportion.

Reginald Harrison strongly urges double vasectomy as equally efficient and less risky than castration, but points out that only one side should be operated on at once. It has the advantage that patients will more readily submit to it, but experience shows that

the prospect of benefit is not so good as when the more radical operation of castration is undertaken.

Within the past three years Bottini's operation, or destruction of the hypertrophied middle lobe by an electro-cautery introduced through the urethra, has been revived, the technique has been improved by Freudenberg; and many surgeons, both on the Continent and in England, now speak highly of this line of treatment.

Meyer has collected 164 cases, of which 80 were cured, 40 greatly improved, and 8 died from the operation.

PRURIGO.

The treatment of this affection is most obstinate, and in the severe form described by Hebra it is almost hopeless.

Prurigo senilis, as maintained by Pye-Smith and other dermatologists, is only phthiriasis. This is rapidly cured by the specific treatment mentioned under *Pediculi*, page 669.

For the ordinary forms of true prurigo, internal remedies, the best of which is Cod Liver Oil or animal fats in abundance, are necessary. Every measure which increases the constitutional vigour and strength of the patient should be persisted in for long periods. Arsenic, Iron, Phosphorus, and Quinine are drugs which, along with Cod Liver Oil, may be taken for one or two months in rotation. Small doses of Perchloride of Mercury, say $\frac{1}{2}$ grain, may be advantageously given for a fortnight or a month after the temporary suspension of the above remedies. Over-feeding, when possible, should be aimed at.

Some benefit has been obtained by the hypodermic injection of small doses of Pilocarpine, of Ergot, and, according to Shoemaker, of $\frac{1}{4}$ to $\frac{1}{2}$ grain Hydrochloride of Cocaine.

By the mouth Kaposi gives large doses of Carbolic Acid, whilst others have given this drug in conjunction with pilocarpine hypodermically. Thyroid feeding and Antipyrine are recommended. Crocker gives Cannabis Indica.

Local treatment is of considerable importance, and, if carried out with patience and perseverance, the disease may be kept in check in the worst cases and even in severe cases may be ultimately banished. In children, the management and removal of the disease are, for the most part, not so difficult. (See under *Pruritus*.)

Warm baths should be given frequently and these may be made alkaline by adding about half a pound of Bicarbonate of Soda to a large bathful of water, or Soft Soap may be used, the object being to get rid of the increased growth of superficial cutaneous cells which have become dry and dead. After each warm bath, and as much gentle friction as will, without increasing the irritation, cause the removal of the loose layers of the cuticle, the patient's body should be well dried, and an animal fat should be thoroughly rubbed in. If this be carried out every night for a considerable

period, it is surprising how soon the prurigo will show signs of yielding. Lard, Cod Liver Oil, and Lanoline are the best substances forunction. The latter is preferable if the patient can get over its disagreeable stinkiness. Cod Liver Oil is valuable, but its disagreeable odour, which increases after it has become mixed up with the dried scales on the surface of the body is a great barrier to its use, but in the case of children it certainly is the best remedy. Naphthol, in the form of ointment (1 to 20) is recommended by Kaposi; it may be rubbed in after the alkaline bath.

Gradually the animal fats may be laid aside for an anointing oil, consisting of pure Almond Oil 9 parts, and Oil of Cade, 1 part. Lately massage has been successfully employed.

Scratching is to be avoided in every possible way, and in the case of children woollen gloves should be tied on the hands to prevent injury by the finger nails. Any eczema caused by scratching will require appropriate treatment, and when the pruritus is very distressing any of the remedies mentioned in the following article may be tried. Sedatives at night may be needed, but Opium should not be given.

PRURITUS

Is constantly mixed up with the above affection, and there is consequently much difference of opinion and confusion about the management of cases. Accepting pruritus as a sensation of continual itching, without the presence of the papules characteristic of prurigo, the first step in its treatment will be to remove any cause when this can be made out. Diabetes, gout, Bright's disease, jaundice, dyspepsia, and other ailments may be the direct cause, and will afford the true indications for correct treatment; whilst, upon the other hand, various local causes may be at work, and these should invariably be looked for diligently. Thus, fissures or cracks, pediculi, scabies, ringworm, and the irritation produced by certain woollen fabrics, may be the cause, upon the removal of which the pruritus rapidly disappears. In other cases it appears to depend upon a neurosis (true prurigo, which generally dates from infancy), and must be met by remedies which will tend to depress or blunt the exalted sensibility of the fine nerve endings in the skin, as Bromide of Sodium in large doses, Cannabis Indica, Carbolic Acid (3 grs.), Ichthyol (10 grs.), Antipyrine (10 grs.), Tincture of Gelsemium (10 min.), Pilocarpine (½ gr.), Atropine, Digitalis, and Ergot.

The following may be found useful:—

Fiat pil. Tales xxiv. St. unam omni nocte.

Shoemaker has obtained excellent results in cases characterised by anæmia and debility from Cod Liver Oil, in daily doses of 1 to 2 drachms, injected into the subcutaneous tissues of the back. At the same time, and in all cases, electricity and massage may be relied upon to improve the general condition and afford comfort. Mild local Faradisation with central galvanism he finds most effective in nervous, prostrated patients. He states "that the electric treatment, combined with proper internal medication, has in my hands ameliorated the condition of many to whom life itself, under the horrible attendant sensations, had become a burden, and has in very many instances effected a permanent cure after all other treatment had failed."

Baths are of the greatest service. The warm Alkaline bath, containing about 8 to 12 oz. of Bicarbonate of Potassium, generally affords temporary relief, and if used before a good half-hour's general massage its effects are often very marked at bed-time, inducing sleep. Sulphuret of Potassium has been used as a bath and found very beneficial, though the writer has generally found it to aggravate matters, owing to the very common traumatic eczema induced by previous scratching. Nearly every one of the numerous sedative baths used in the practice of skin therapeutics affords more or less relief from the sensation of itchiness. The starch bath is a favourite, and after coming out of it the skin may be dusted over with the dry powder, mixed with Salicylic Acid (1 in 25).

Janicke relies upon the removal of the superficial epidermis for the relief of the itching, and finds great improvement by the use of a soft brush for 15 minutes two or three times a day, and the use of an evaporating lotion or Lanoline ointment.

Of drugs for local application, Menthol is the most reliable. It may be used in innumerable ways. Saalfeld dissolved half a drachm in $1\frac{1}{2}$ oz. of pure spirit of wine, and this may be painted over the affected region in the same way as the writer has brushed on the *Oleum Menthae Piperitæ* with a camel's hair brush. The menthol cone may be rubbed on the skin, after moistening the latter with spirit.

Two drachms of Menthol rubbed up with $\frac{1}{2}$ oz. Olive Oil and 1 drachm Chloroform may be made into an ointment with $2\frac{1}{2}$ oz. lanoline.

Cocaine has been extensively employed with success. The ingenious method of Porritt is the best where the region affected is of limited extent. He uses a cone of cacao butter impregnated with 2 per cent. of cocaine. As this is rubbed over the irritating patch the warmth of the skin melts the butter, which forms a soothing, emollient shield over the irritable nerve endings in the skin.

Machiavelli combines various drugs with the cocaine. The following is an elegant and valuable formula where the itching is bad at night:—

- R. *Cocaine Purif.* gr. iv.
 Hydrargyri Ammon. Chloridi gr. xv.
 Zinci Oxidi 3j.
 Vaselin Albi 3x. *misce.*

Fiat Unguentum.

Carbolic Acid is often useful. A 1 in 80 lotion may be sponged over the skin at night, or carbolic oil (1 in 20) may be smeared over the body at bed-time, or any firm ointment may be employed. Lanoline, which alone is an excellent sedative in pruritus scari, may be combined with the carbolic acid.

Creosote is better than carbolic acid, and the following combination is excellent:—Creosoti (Beechwood) 1 dr., Lanolin 1 oz.

The previously mentioned authority recommends Carbolate of Sodium in persistent itching of the female genitals in the following form:—Carbolate of Sodium, 25 grammes, Eau de Cologne 75 grammes, Glycerin, 100 grammes, Distilled Water, 300 grammes.

This may be followed in bad cases by compresses soaked in the following:—Hydrochloride of Cocaine, 75 centigrammes; Alcohol, 100 grammes; Distilled Water, 300 grammes.

Startin's Lotion consists of 1½ drs. each of Borax and Carbonate of Ammonia, 1 oz. Glycerin, 3 drs. Dilute Hydrocyanic Acid and Water to 16 oz. To be diluted with 2 or 4 times as much water before application.

Juben uses the following in pruritus vulvæ:—

- R. *Acidi Salicylici* 3j.
 Zinci Oxidi Purif. 3iii.
 Glycerini Amyli 3iii. *misce.*

Fiat Unguentum.

Madden, after washing the parts with weak sublimate solution, applies a 1 in 10 solution of Methyl-Blue, and gives it internally in doses of 1½ grs. in capsules; the objection to its use is that it dyes the parts permanently.

The same measures may be employed for pruritus ani, but as this depends so often upon the presence of hemorrhoids, fissures, or other abrasions, the cause will require removal (see page 56).

Tar, Liquor Carbonis Detergens, Calomel, Camphor, White Precipitate, Friar's Balsam, Borax, Chloral, Corrosive Sublimate, Ichthyol, Iodoform, Naphthol, Petroleum, Bismuth, Nitrate of Silver, Sulphur, Tobacco, Salicylic Acid, Alum, Zinc Carbonate, Tannin, Lead Salts Acetic Acid, &c., are examples of drugs which have been found useful in local and general pruritus.

Formulae for pruritus might be multiplied to the extent of the

present volume. Enough has been given to show the principles upon which relief of the itching may be obtained.

For local pruritus, especially of the anus and female genitals, the writer has discarded every drug save the Unguentum Conii. This very often acts like a charm. Sometimes he has added to it the following:—Creosoti Purif., m. xxx., Unguent. Conii, ʒi.

At bed-time a small cold water enema should be given, after which the parts should be freely smeared over with Hemlock Ointment, some of it being pushed up the vagina or rectum by the finger. This often speedily relieves even in diabetes.

In obstinate cases of vulvar itching, a weak continuous current is of great value. (See under Anus, Pruritus of, page 56.)

PSEUDO-HYPERTROPHIC PARALYSIS—See Paralysis, Pseudo-Hypertrophic (Page 668).

PSOAS ABSCESS.

Under Abscess the treatment of chronic varieties like the present has been already discussed. As a rule, Lister's method of treating psoas abscess upon the strictest antiseptic lines is the one which should invariably be adopted when the case comes before the surgeon prior to the discharge of the pus. There is no urgent reason, in the great majority of cases, for hasty action. The writer once was prevented making a free incision into a large psoas abscess which had already implicated the deeper layers of the skin. During the night the abscess burst into the bladder, and a rapid (almost immediate) recovery resulted.

The first principle to be laid down here, as in all spinal abscesses, is to secure fixation of the diseased vertebrae. For this purpose plaster jackets and felt cases are quite useless. An accurately fitting steel brace should be applied. When this has been worn day and night for some time, and is quite comfortable, the question of operation on the abscess may be considered, as nothing so materially contributes to its success as the application of the support on the operation table. The most satisfactory method is that recommended by Barker. A small incision, about one inch long, is made over the most dependent point of the abscess, through this a long flushing curette is introduced, and the abscess cavity thoroughly scraped out. A stream of boiled water or saline solution flows continuously through the curette, so as to wash out the debris; next the abscess track is mopped out with long strips of gauze, which dry it and bring away remnants of debris; finally the opening is closed without drainage, and firm pressure is applied over the abdomen so as to cause the walls of the sac to fall together.

Where necessary a second opening may be made in any convenient position along the track of the abscess, and this also will be closed without drainage.

If carried out under strict aseptic precautions, Barker's method gives excellent results.

Probably most surgeons, sooner or later, regret draining one of these deep-seated abscesses. Septic infection is almost inevitable, and with it sets in a train of hectic symptoms that can rarely be subdued.

Treves recommends exposure of the bodies of the vertebrae and removal of the diseased bone.

This operation may be carried out where the dorsal vertebrae are involved, the transverse processes and vertebral ends of the ribs being first removed. Mr. Kirk has shown several cases in which this was most successfully done. As a rule, double psoas abscess is unfavourable for operation.

Where a sinus already exists, it should be kept as aseptic as possible, and may be syringed out daily with a weak solution of Carbolic or Boracic Acid.

The after-treatment of these cases gives good scope to the physician, and the general lines for their management will be such as will be suitable for most scrofulous or debilitated patients recovering from exhausting diseases; thus, diet is to be as generous and varied as the patient can partake of; tonics, especially Iodides, Iron, and Quinine, with Cod Liver Oil, abundance of fresh air, and removal to a bracing sea-side resort, with the exhibition of whatever special remedies appear to be indicated in the case.

See under Abscess, page 15, for the methods of Wile, Bruns, Verneuil, and others. These have been successfully applied in a modified way to the treatment of the varieties of psoas abscess. Under Tuberculosis will be noticed Lannelongue's plan of injecting solution of Chloride of Zinc into the tissues surrounding spinal and other abscesses.

PSORIASIS

The constitutional treatment of psoriasis, with our present knowledge, is a simple matter, as in very many cases the patient appears to be in robust health, and there is no indication whatever for drugs beyond the presence of the eruption. It is true that sometimes anaemia is present, and hence the recommendation to give Iron. Some authorities still regard psoriasis as evidence of a gouty or scrofulous diathesis, and recommend treatment accordingly, but, as a rule, such drugging, based as it is upon a wrong hypothesis, only leads to disappointment and mischief. Diet should be such as will be best calculated to maintain a perfect standard of health, and the fancy dietaries insisted upon by some specialists are as useless as they are irksome to the patient. It is nevertheless a good practice to alter the patient's diet periodically, and a few months' course of vegetarianism is

often most beneficial in those who eat too much animal food. Morris lays stress upon the importance of clothing which does not cause irritation of the skin, and which guards against chills. He emphasises the value of a warm equable climate.

Drugs which are supposed to have a specific action upon the disease when administered internally are.—Arsenic, Phosphorus, Iodide of Potassium, Chrysarobin, Turpentine, Copaiba, Tartarated Antimony, Tar Water, and Carbolic Acid.

Arsenic stands easily at the head of this list. It has so frequently been proved to be of service that it should be always selected in preference to any other drug, and only after it has been found to fail is the physician justified in resorting to other agents. It must be commenced in small doses, say 2 minims of Fowler's Solution, which should be steadily increased till 5, 7, or even 10 minims are given three or four times a day, diluted with water, immediately after or along with food. The drug may be pushed till the physiological effects are noticed, and after redness or irritation of the conjunctiva the dose may be diminished or suspended for a short time. This treatment may be continued for many months, and should not be stopped upon the removal of the eruption. The Asiatic pills, each containing $\frac{1}{12}$ to $\frac{1}{8}$ grain, the Liquor Soda Arsenatis, or the Liquor Arsenici Hydrochloricus in the same doses as Fowler's Solution, may be given. $\frac{1}{8}$ grain of the Arseniate of Iron three or four times a day may be prescribed in the form of pill. Shoemaker reports success by giving the Soda Solution hypodermically, $\frac{1}{16}$ to $\frac{1}{8}$ grain of the salt, dissolved in water, being injected daily into the deep cellular tissue of the back or buttocks. The popular French compound, Cacodylate of Soda will probably be found superior to all other arsenical preparations when administered hypodermically (see page 45). It must be remembered that arsenic should never be given in acute cases, and when long administered, hyperkeratosis of the palms and soles may be induced, as evidenced by great warty thickening of the skin in these regions.

Phosphorus is believed by some to possess a specific action upon the disease, and the writer has occasionally seen good effects follow its administration in doses of $\frac{1}{16}$ grain in pill immediately after food.

Iodide of Potassium has been given in heroic doses (in ordinary quantities the writer has found it to fail always). Haslund gives very large doses, and Lunsun reports a rapid cure in a chronic case by commencing with 45 grains daily, and pushing the drug till 225 grains (over $\frac{1}{2}$ oz.) were daily administered. The recent reports show that this drug is worth trying, but there are not yet data for an expression of opinion about its permanent value, though the immediate effects are striking. The limit of 100 grains daily need not be exceeded. Gutteling gives up to 2 oz. of the drug daily.

The Iodide may be given in large doses, in combination with Arsenic, and the writer has given the following :—

R. *Potassii Iodidi* *ʒij.*
 Liquor. Arsenicalis *ʒiv.*
 Glycerini Purif. *ʒiiss.*
 Aquæ Camphoræ ad *ʒviij. misce.*

Caput ʒij. ter in die ex cyatho vinario aquæ post cibos.

Each dose of the above will contain half a drachm of the Iodide and the total daily allowance will fall short of 100 grains.

Chrysarobin has been given internally with some success but often produces violent vomiting, diarrhoea, and griping, even in doses as small as $\frac{1}{2}$ grain in pill. Nevertheless the writer has seen benefit from it, and believes it worthy of a trial in those cases of psoriasis guttata where its external application is impracticable. Where it can be applied freely to large scaly patches he believes that its internal use is unnecessary.

Crocker recommends Turpentine, which he gives as an emulsion or in capsules, and increases the dose till 30 minims are taken thrice daily.

Copaiba, Antimony, Colchicum, Carbolic Acid, Creosote or Tar, Mercury, Sulphur, Alkalies, Cantharides, and various diuretics, purgatives, and alteratives have been vaunted but beyond correcting some temporary or accidental complication they cannot as claim to any specific action. Anderson recommends the best mentioned drug, and Malcolm Morris has obtained excellent results from Tartar Emetic in the early stage, and in acute varieties of the disease where arsenic is contra-indicated.

Cod Liver Oil always does some good in the treatment of the affection in children, and in lean adult subjects it often appears to assist the action of arsenic or phosphorus.

Bramwell has published successes from Thyroid Extract, and though the writer's experience has been unsatisfactory, he is satisfied that the agent does good in some cases. Bramwell pushed the drug till thyroidism was very marked, sometimes giving 30 5 gr. tabloids daily. Busch records 11 cures in 24 cases, but other dermatologists have generally failed and Bramwell's dosage would probably now prove dangerous with the improvements in the manufacture of the present tabloids. Bourboule and other arsenical waters are often very beneficial, especially when used in conjunction with sea bathing.

Local treatment of psoriasis is of more importance than the constitutional and every physician can recall examples of the disease successfully treated by agents locally applied. Many authorities believe in its parasitic origin, and some cases of transmission of the disease by contact have been recorded. In

practice it will be wise no matter what local applications are used to persist in the internal use of Arsenic at the same time. Warm baths or hot packs are essential for softening the scales before applying local agents. Prolonged immersion in a bran bath, or in a bath in which a handful of soda bicarb. and borax have been dissolved, is very useful.

The writer still believes that Chrysarobin affords the best chances of success in the greatest number of cases, but it should not be used in the acute stages. The following extract is from the 7th Edition of his work on "Materna Medica and Therapeutics," page 364, and will convey his experience and judgment upon the value of the drug.—"It is a remedy whose value in chronic psoriasis can hardly be exaggerated. An ointment of from $\frac{1}{4}$ to 1 drachm mixed *intimately* with 1 oz. of heated lard or Vaseline, rubbed twice daily into the scaly patches of this disease, rapidly causes their disappearance. It frequently produces a painful erythematous inflammation of the surrounding healthy skin, which prevents its use by some patients. The writer, after considerable experience of Chrysarobin, is satisfied that this need never occur if the application be confined exclusively to the diseased islands, and not permitted to touch the healthy skin. This little point he believes to be the secret of the success of the treatment. Dr. Fox has advised the application of Chrysarobin made into a paste with water, smeared over the spots, and covered with Collodion. Traumaticine will be found even more satisfactory.

"It acts both locally and constitutionally. Its local action may be seen by rubbing the ointment into the diseased spots on one side of the body of a patient affected with psoriasis. In a week or ten days the skin on the side so treated shows decided signs of improvement not in the least apparent on the opposite, and as the diseased patches begin to disappear under the direct application of the remedy, those regions to which it has not been applied eventually begin to show signs of improvement also; and the writer found by persistently continuing the application to the spots originally so treated, the entire surface of the body cleared up. This is probably caused by its absorption into the system and its conveyance to all the diseased areas. The experiment is not an easy one, however, owing to the difficulty of preventing the ointment being diffused over the entire cutaneous surface, and the application cannot be too long continued, because an ointment which causes no irritation whatever for a few weeks, so long as the spot to which it is applied remains scaly and diseased, soon acts as a powerful irritant to the same spot as it becomes resolved and healthy."

This observation is strengthened by the experiments performed by Lewin and Rosenthal upon rabbits. They found that an ointment of Chrysarobin, when applied externally, was absorbed and partly converted into chrysophanic acid in the system. A part not oxidised was demonstrated in the urine.

The deep purplish discolorations which it produces on the air and bed-linen are barriers to its use, and great care must be exercised in applying the ointment to the face, as it causes redness of the eyelids, with discoloration, though it can be applied to the scalp (15 grs. to 1 oz.) with benefit.

Brooke's Salve Sticks are a splendid way to use Chrysarobin. Laeberrmann finding that Chrysarobin had such powerful action for Oxygen, thought that its action depended upon this, and that in its oxidation to chrysophanic acid it robbed the parasites of their oxygen and killed them. He has discovered an almost identical substance, which he now uses instead of chrysophanic acid.

This is Anthrarobin, which has been successfully employed in several cases as a 10 per cent. ointment, which may be applied to the face and eyelids, though it leaves a yellow stain. It is milder than pyrogallic acid. It may also be painted on as a 15 per cent. tincture, after scrubbing with soap and water to remove the scales.

The writer has obtained the best results by painting the affected patches with a paste of chrysarobin made by rubbing it up with water or spirit, and over this applying a piece of rubber adhesive plaster. In using the Salve Sticks the greased spot may be similarly covered over. By these means several points are gained: (1) Only the diseased patch is subjected to the action of the drug, the healthy skin being untouched. (2) More concentrated preparations can be applied. (3) The action of the drug upon the diseased spot is continuous. (4) No soiling of linen or bed clothes or discoloration of the face occurs. Unna and Stelwagon use the acid in the form of medicated plasters. These are very valuable for large patches.

Of the most recent methods of employing chrysarobin locally the most elegant and efficacious is the *Glycerinum Saponatum* mentioned upon page 262. Hans Hebra adds 10 per cent. of chrysarobin to the 92 per cent. mixture, this is known as the *Chrysarobin Glycerinum Saponatum*.

Tar is the local remedy which has still the highest place in the treatment of psoriasis amongst the majority of skin therapists, and with many skilful physicians the following epitome of its treatment of the disease would be endorsed—Cover Arsenic internally; remove the scales by bathing, packing or scrubbing; rub in the B.P. Ointment of Tar, and make the patient sleep in his tarry underclothing.

The tar treatment may be carried out in many ways. The *Liquor Carbonis Detergens* may be made into a less objectionable ointment than the official *unguentum picis liquidæ*. 2 drachms to 1 oz. of lanoline may be used, or it may be mixed with spirit lotion, 1 in 10, which can be applied upon lint and covered with oiled silk or thin mackintosh, or the liquor may be brushed in its full strength over the spots and be allowed to dry.

Huile de Cade, or Juniper Tar, is a more agreeable preparation in the *pix liquida* obtained from the *pinus sylvestris*. It may be used with oil or used as an ointment (1 to 4 of spermaceti ointment), or the following excellent application may be used. —

R. *Olei Cadini*
Ceræ Flavæ ana partes æquales.

Misce et fiat unguentum cum calore.

Vidal makes the oil of cade into a soap with an equal quantity glycerole of starch and 5 per cent. of soft soap. This is rubbed every evening and washed off in the morning.

Various other tarry preparations are in use, *z.*, *Oleum Fagi* (beech tar) and *Oleum Rusci* (birch tar), but Brooke maintains that the *Liquor Carb. Detergens*, which is an alcoholic solution of all tar, and the official *Liquor Picis Carbonis* are in every way more reliable. Hutchinson combines the Tar and Chrysophanic acid plans in an ointment containing 10 grs. White Precipitate, 10 j. Chrysarobin, 20 minims Creosote, and 10 minims of *Liquor Carbonis* to 1 oz. Benzoated Lard. This is perhaps the best of tarry applications for psoriasis.

Hot baths, which are so valuable in the treatment of psoriasis, are an essential part of a successful tar cure. The patient should lie in a large warm bath for 30 to 60 minutes, during which time he may apply gentle friction by a piece of soft flannel or by a soft brush to the scaly patches till the epithelial products are removed. The addition of an alkali like the Bicarbonate of Soda or Borax, to the extent of about 4 oz. to a moderate sized bath, is a great advantage. After coming out of the bath and getting dried he should roll himself up in a blanket till the cuticle loses its retained moisture, after which any of the tarry preparations just mentioned may be freely rubbed in.

Some authorities, as Hebra and Kaposi, advise the application of Green Soap daily till the scales are removed and a raw oozing sore becomes visible. The spirituous solution of the soap may be rubbed in with strong friction, or the patches may be scrubbed with soap and water by the aid of a brush. Ellinger employs iodine to remove the scales.

The writer has never seen any benefit follow these painful measures. When he wishes to get the scaly patches cleansed he resorts to the warm Alkaline bath and local wet packs. Large patches soon yield to a pad of lint soaked in water or a weak alkaline lotion, covered by oiled silk, and kept continually in its place by comfortable bandaging.

After such preparatory treatment the action of local remedies is much more rapid and satisfactory, and some physicians content themselves with these ablutory measures and the internal use of arsenic, assisted by diuretics or diaphoretics. Where baths are

not obtainable, Jamieson recommends that an ointment consisting of 10 parts of Carbonate of Ammonia, 25 of Lanoline and 5 Cold Cream, be applied daily to remove the scales, which it does effectually do.

Creolin (5 parts), Vaseline (100 parts), Thymol (1 part) (20 parts). Naphthalin (1 part), Lard (8 parts). Creosote (1 part), Lard (8 parts), Ichthyol (50 parts), Vaseline (100 parts). Res Naphthol (1 part), Lard (9 parts). Gallanol (1 part), Lard (20 parts). Pyrogallic Acid (5 to 10 parts), Lard (100 parts), and external surfaces Besmer paints with a solution of 90 grs. each of Pyrogallic and Salicylic Acids in a little ether and spirit to which 21 of Flexible Collodion is added.

Pyrogallic Acid is undoubtedly efficacious; but its use appears to be not without danger, as several fatal cases are reported. Jarisch used an ointment of one drachm to the ounce, but a much weaker preparation may be used with greater safety; 15 to 20 grains per oz. is perfectly safe and unirritating, but it should not be applied to the entire body, as its absorption may give rise to alarming fever, strangury, and melæna. It stains black or dark brown, but weak ointments may be safely applied to the head and face.

Vlemingh's Solution (Pentasulphide of Calcium) is applied by rubbing or dabbing it into the affected patches with a strong linen or flannel till the skin bleeds, after which it is washed off, and cold cream or lanoline applied.

Shoemaker gives the following formula of Wilkinson's Ointment, as modified by Hebra:—

R. Sulphuris Sublimati
Huile de Cade ana ʒss.
Saponis Viridis
Adipis Preparati ana ʒj.
Crete Preparata ʒiiss. misc.

Hebra also used Tar, Spirit, and Green Soap (in equal parts) as an application in chronic cases, with large isolated scaly patches.

Mercurial preparations are used, and upon the bacterial theory there has been a revival of the treatment by weak ointments of Corrosive Sublimate (1 in 50), Bimodide (1 in 100 to 1 in 50), Ammonio-Chloride (1 in 15), Nitrate, as Citrine Ointment and the Oleate, 10 to 20 per cent., have been advocated.

Rochard's Ointment consists of—

R. Hydrarg. Subchlor. ʒss.
Iodi Purificati gr. xi.
Unguenti Simplicis ʒxiv. misc.

Fiat Unguentum.

Shoemaker, in hospital practice, uses equal parts of Citrine and Tar Ointments.

In private practice he recommends an ointment made by diluting the official ointment of the Nitrate or Oleate of Mercury with one-half or two-thirds of Lard or Butter, adding half to one drachm of either Naphthol or Chrysarobin to each ounce.

Turpentine, Iodide of Sulphur, Iodide of Lead, and pure Iodine, have been also used.

There is not yet sufficient data to enable one to arrive at a conclusion regarding the values of Hydrochloride of Hydroxylamine, Hydrochloride of Hydrazine, or Hydrazine Salicylic Acid or of Aristol—the new Thymol derivative—or of Euprophen or Ethylate of Sodium.

Above are the most frequently employed combinations, though formulæ might be given without end each specialist having his favourite combinations. In the treatment of a diseased condition like psoriasis, which varies little in its characters, and cannot be well said to have "stages" in its progress, as is the case with eczema, the great mistake which the student is sure to make is to begin with a local application, and before it has had time to act change it for another, and so on all through the progress of the disease. Selecting either the Tar or Chrysarobin, it will be much better to stick to it all through in every case till experience proves that it is not going to give satisfactory results. Life is too short to attempt to gain an experience of the result of every special application, and it requires years of patient watching and observation in order to thoroughly master all the little minutiae required in the successful use of any one of the above remedies.

Electricity used either as the constant, interrupted, or static current has been reported as giving good results in several cases when locally applied, and it need not interfere with any of the above applications.

The point of greatest importance in the treatment of psoriasis is well emphasised by Brooke, who insists upon the use of the local remedies long after the disease appears to be removed, and upon their immediate use again upon the reappearance of the first papule of the disease.

PTYALISM.

Increased flow of saliva is but a symptom of various affections, and its treatment will depend upon the cause which, when diligently sought out, is to be met by appropriate remedies. Thus various local, tongue or mouth affections, as delayed dentition or aphthous stomatitis in children and secondary syphilitic affections in adults, may cause the salivation, which will be readily checked by treating the primary cause.

When ptyalism is caused by the administration of mercurials, it should be instantly stopped in the great majority of cases, for, as

already pointed out, it will be seldom necessary to cause salivation during the treatment of syphilis or any other affection by mercury. With the suspension of the drug the increased flow of saliva as a rule speedily subsides, but sometimes profuse salivation, though difficult to control may be met with where mercurials have been administered by quacks. The best local application will be Chlorate of Potash (1 in 40), which should be used as a mouth wash every hour, after first cleansing the buccal cavity with a weak Solution of the Permanganate of Potassium. Before and during a course of mercury the greatest attention should be paid to the state of the gums and teeth in order to prevent ptyalism. This must be carefully attended to at Aix, and is one of the details upon which the great success of the treatment there depends.

When in ptyalism from excessive mercurialisation the gums become much swollen and ulceration has occurred, astringents will be required. Alum (1 in 40), Chloride of Zinc (2 grs to 1 oz), Tannic Acid (1 in 40) Decoction of Oak Bark, or other vegetable astringents may be used. The overwhelming fetor may be removed by weak solutions of Chlorinated Lime or Soda, or by a mouth wash consisting of Carbolic Lotion (1 in 20) or Iodine (1 of min. in 40), or weak Condy's Fluid.

The Glycerin of Borax is a most efficient local application and it must be used almost continuously.

Internally the Chlorate of Potassium may be given with advantage, and if combined with a Mineral Acid or Iron preparation containing a free acid, a better effect will be obtained.

Stimulants may be needed in bad cases, and only liquid food can be swallowed.

When ptyalism is the result of some reflex action, the amount of saliva can be easily diminished by the internal administration of Atropine, Belladonna, Hyoscine, or Opium in small doses, until dryness of the throat occurs. It is, as a rule, not advisable to give atropine in cases like mercurial salivation, or where ptyalism has been produced by iodine or other drug. In these instances the increased salivary flow is probably caused by an attempt upon the part of nature to cause the elimination of the poison. The writer, acting upon this theory, has utilized the powerfully stimulating action of Pellitory Root upon the salivary glands in order to encourage the flow of saliva. Several parts of the secretion may be caused to flow away in this manner, where the gums are swollen and ulcerated this plan should not be adopted.

Iodide of Potassium has been given in mercurialism with some benefit, but it is a questionable experiment to try it, as it may greatly aggravate the affection.

Bromide of Potassium has proved useful in the salivation of pregnancy. It may be combined with small doses of Benzoic Acid or Hyoscyamus.

PUERPERAL CONVULSIONS.

There must ever remain differences of opinion regarding the best treatment of any affection till its pathology is cleared up, and in the present state of our knowledge there are widely-diverging views upon the pathology of eclampsia occurring in connection with the later months of pregnancy. Levkovitsch's discovery of the presence of a specific bacterium has not yet been corroborated, and Jurgen's liver theory has not led as yet to improved methods of treatment though some promise of success appears to lie in Nicholson's hypothesis that the condition depends upon a faulty condition of the thyroid gland. The treatment which is based upon the theory that the disease or condition is a purely functional affection, or as regarded by Santos, merely an "acute peripheral epilepsy," is as highly efficacious and as reliable as the treatment based upon the usually accepted theory that the eclampsia "depends upon uræmic poisoning due to an inadequate secretory activity of the kidneys," as maintained by Spiegelberg. Hence, forgetting all theories upon the subject, the physician is justified in adhering to the remedies which a wide and extensive experience has proved to be most valuable.

Prophylactic treatment is of importance, and experience has shown that in those cases of pregnant women who exhibit large amounts of albumin in the urine, attention to the conditions of the kidneys is likely to materially diminish the tendency to eclampsia. The skin, bowels, and kidney should be made to work with activity and efficiency, as already detailed in speaking of the treatment of Bright's Disease.

One of the most powerful prophylactic measures is a diet consisting exclusively of skim milk. This diet might be supposed to act equally well whether the eclampsia was the result of epilepsy or of uræmia, since it is one of the best remedies in either disease when unassociated with the puerperal state. Auvard recommends the milk diet strongly, and Blanc advises full doses of Chloral as a prophylactic where there is much albumin.

O Nicholson recommends Thyroid gland as a prophylactic; when albumin appears he has found it to do good, and he maintains that it is valuable even in the convulsive stage when given hypodermically (15 mins. of Liquor Thyroides every hour or two).

If labour has already commenced, or is about commencing, there need not be any hesitancy about hastening it; in severe cases this must be carried out with rapidity and firmness, the expectant plan of treatment being then abandoned. The steps to be taken will depend upon the stage of the labour already present, and the condition of the os and cervix. As a rule, rupture of the membranes will be the best procedure, after which mechanical dilatation of the os with the fingers, or, better still, the introduction of Champetier de Ribes bag. Where, notwithstanding the puncture of membranes and dilatation of the os or cervix, labour does not proceed as quickly as the urgency of the symptoms would render

necessary, delivery must be accomplished by version or by forceps, and the placenta should be taken away without unduly waiting, avoiding precipitancy.

Whilst labour is being induced or hastened the following measures should be pressed.

Chloroform inhalation, to the extent of producing deep narcosis is an agent of great value in eclampsia, and statistics show excellent results since the introduction of this method of treatment. It checks or prevents the fits, and in the *status epilepticus* it relieves cyanosis and dyspnoea, and according to Dakin it seems to prevent the pyrexia which may occur then. Ether or other anæsthetics may be tried where chloroform is not available.

Chloral comes next in value to chloroform; it should be pressed in large doses when the patient is able to swallow between attacks, or it may be given by the rectum in all cases with advantage, either alone or in combination with the Bromide of Potassium—20 grs. of chloral and 40 of bromide being injected every two, three, or four hours in severe cases.

The best practice is to give chloroform by inhalation and to keep up the effect by chloral and bromides per rectum. If it can be done cautiously, the chloroform can be suspended till the immediate premonitory symptoms or signs of a convulsion are experienced, when the chloroform sponge may be immediately placed over the patient's mouth and nose. Winckel's results from this combined chloroform and chloral method of treatment amounted to a death rate of only 7.6 per cent.

When these measures fail especially in very plethoric subjects the physician should not hesitate to open a vein in the arm by free incision, and let out 12 to 20 ounces of blood. After having let the convulsions return, chloroform must be very cautiously given if at all and, unless they are very severe it will be well to suspend both the chloroform and chloral, and treat with enemata of bromide of potassium (1 to 2 drachms) and hypodermic injections of Morphia. Some authorities always combine morphia with the chloral treatment, and give nothing else, but it is very probable that this method will not give as good results as the chloroform and chloral plan. In some cases all these remedies have been successfully employed when the convulsions have been very formidable.

Trousseau's method by compressing the carotids often stops or very materially modifies the attack, and though not to be entirely depended upon it may be advantageously employed in most cases to gain time till the chloroform narcosis is established.

Whilst the above measures are being used and labour is being hastened, the physician should not omit to stimulate the excretory organs and the ordinary treatment so successful in dealing with uræmia may be safely pushed after delivery has been accomplished. As already detailed, this is based upon the lines of causing the elimination of the retained excrementitious products, and Sulphate

of Magnesia, or Compound Jalap Powder, should be freely given. Elaterin or Elaterium has so often failed in the writer's hands in critical cases that he prefers to trust the ordinary salines.

The skin must be acted upon powerfully. The best of all means for this purpose in puerperal eclampsia is the free use of the hot pack. Pilocarpine has been so frequently found to cause oedema of the lung that its use has been practically abandoned, though the writer has pointed out that if its administration be delayed till sweating has already been induced in the hot pack it may be used with comparative safety. *Veratrum Viride* in full doses of the tincture hypodermically has recently many advocates (150 minims have been given in twelve hours).

The writer has chanced to meet with puerperal convulsions in several cases after delivery had been accomplished in the normal manner, and in these eliminatory treatment was most satisfactory, free purgation by Sulphate of Magnesia and Jalap Powder, with the hot Mustard pack or Mustard blanket bath, acting rapidly and effectually.

In desperate cases the best treatment will be that suggested by Bozzolo for uræmia, and mentioned upon page 86. It will consist in the removal of a fair quantity of blood by opening a vein in the arm, after which weak Saline Solution may be injected subcutaneously or into a vein, with the view of diluting the remaining blood left in the body. (See also under Anæmia, upon page 41, for the details of the methods of injecting salines.)

Many reports are forthcoming of success following the injection of warm saline solution into the colon, and this should be done before waiting to empty the uterus. It is recognised that this method is safer than that of intravenous injection, which may cause serious overstrain of the heart. It will doubtless become the routine method of treatment to be immediately resorted to as soon as the convulsions appear.

PUERPERAL FEVER.

For the proper treatment of this condition the fact must be grasped that there is no such disease in a specific sense; the condition is one of septic poisoning, and this may be (1) mild, as in the so-called "Sapremia or mild septicæmia," where the ordinary putrefactive organisms (growing on the surfaces of the vaginal or uterine membranes, secrete their chemical poison which is absorbed into the blood, or (2) severe where the pathogenic organisms find their way into the blood and multiply in it.

Prophylactic measures are of primary importance. These may be summed up in two words—absolute cleanliness. The patient, her house, bed linen, and surroundings should be as clean as possible. The hands, dress, and instruments of the accoucheur and of the nurse must be placed beyond the possibility of conveying micro-organisms. Antiseptics are of vital importance, but the accoucheur should not be led into the error of relying upon them

solely. Cleanliness of the most scrupulous degree is all that is necessary. When this has been achieved in every detail, antiseptics or disinfectants may then be used to render "assurance doubly sure."

A rigid examination of the patient's surroundings should be made. There is little use in the scrupulous cleanliness of the attendants if the lying-in room should chance to be in direct communication with a sewer, or if friends and visitors are promiscuously admitted to her chamber laden with the germs of puerperal fever, erysipelas, or scarlatina.

The irrigation of the vagina during labour, especially after vaginal examination, is of great importance, and the examination should be as few as possible. After careful and prolonged cleansing of the hands and arms of the attendant by soap and water, they may be rinsed in a weak Carbolic Lotion (1 in 50), or in a dilute Solution of the Permanganate of Potassium. Either of these may be used as a vaginal douche.

Perchloride of Mercury—the most powerful germ destroyer—has been very much used of late years, a solution of 1 in 1,000 being employed as an antiseptic solution for the hands and instruments. The serious mishaps which have been known to follow its routine use, especially as a vaginal or uterine douche, have led to its now being much less frequently selected, but in disinfecting the hands, instruments, &c., it has no rival.

The external genitals should be carefully sterilised before labour and daily afterwards.

The vagina should be irrigated after delivery, and Spiegelberg lays down the rule that if the hand has been introduced into the uterus its cavity should be well washed out.

Though it is not generally considered necessary where aseptic midwifery is the rule to daily wash out the vagina after labour with antiseptics, unless where there are considered to be special reasons, the writer invariably followed the practice of having the canal irrigated twice a day for the first fortnight and so on. I never had a case of puerperal fever occurring during 25 years, I think it possible that it may be owing to this precaution. There is no danger or drawback to the practice if carried out by a skilled nurse, provided that weak Permanganate Solution (about 1 oz. of Condy's Fluid to 2 quarts of tepid water, be used, and the vagina pipe be not passed up into the uterus. Sometimes severe pain and shock follow the injection of fluids into the uterus when there is no outlet for the flow, and when antiseptic pressure is maintained. In administering the vaginal douche after labour one hand should be firmly kept upon the abdominal wall over the uterus in order to prevent distension of the organ by the injection. If Perchloride of Mercury be used as a routine douche for the vagina, 1 in 5,000 is quite sufficient. The practice of securing the expulsion of all clots from the uterine cavity after labour, by prolonged kneading and the administration

of Ergot, is universally recognised as a valuable prophylactic measure.

The value of strict asepsis has been recently emphasised by Professor Byers in contrasting the mortality from puerperal fever in private practice compared with the exceedingly low death rate now furnished by the chief lying-in hospitals.

When symptoms of septic poisoning actually occur, as evidenced by pyrexia, rigors, &c. the vaginal irrigations, if not already in use, should be commenced. A 1 in 4,000 Corrosive Sublimate douche may now be used every eight hours, and if there be fetid discharge, or abrasions, or other special reasons, double this strength may be employed.

At this stage Dakin advises the administration of Ergot with the view of expelling any clots or other decomposing matter. But where the symptoms are formidable the finger should explore the uterus, and a warm stream of 3-6 pints of a 1 in 2,000 sublimate solution should be injected through a Budin's catheter, by means of the glass reservoir apparatus, under a low pressure, as the patient lies upon her back.

Shocking carries out a system of *permanent* irrigation. Deipser disregards all ordinary antiseptics, and relies upon a stream of hot water (122° F.).

The Russian method of constant irrigation of the vagina by a stream of hot carbolic lotion (120° F.) has been reported as giving excellent results. The apparatus of Morosow is used. The Italian practice is to *continuously* irrigate the uterus by a stream of carbolic solution by means of a Breus-Bozeman-Fritsch tube or a Kurz catheter, the flow being kept up for hours till the temperature falls. Creolin (2 per cent.), Thymol (1 in 1,000), or Perchloride of Mercury (1 in 2,000) may be employed as a douche.

Some authorities do not hesitate to recommend curettage as a routine agent before irrigating the uterus, and others recommend instead swabbing of the interior with strong Carbolic Acid, Iodized Phenol, or Peroxide of Hydrogen.

The Committee of the American Gynecological Society condemn curettage and total hysterectomy after full term delivery, and believe that a large part of the excessive mortality is caused by the curette.

When, notwithstanding the thorough disinfection of the uterus and vagina, the deepening of the symptoms show that the virus has reached the general blood stream, other measures must be adopted.

Fever will claim attention. When this is moderate and the symptoms only indicate a minor degree of septic poisoning ordinary diaphoretics are indicated, but when a persistent high temperature is recorded, Quinine in large doses is indicated. Ten grains may be given every 4 or 6 hours till the full physiological effects of the drug are produced, or a dose of 30 grains may be given at once.

Antipyrine and Antifebrin have been used, but in the treatment of puerperal fever quinine maintains its supremacy, inasmuch as it often fails even in 20 or 30 grain doses to reduce the temperature. In cases where it thus fails in reducing fever heat, it has nevertheless to have done good as a tonic, or stimulant, and hence its popularity in a disease characterized by prostrated prostration and often associated with grave cardiac weakness.

Quinine is useless in severe hyperpyrexia, and the new antipyretics are not to be depended upon and the patient will speedily sink unless the fever heat which is incompatible with life be removed by the only reliable agent—cold water. This may be used as the cold wet pack in which the patient's entire body is submitted to the action of water at 60° F. or lower by being enveloped in a wet sheet. If the physician pours cold water continually over the wet sheet all the advantages of a cold bath are obtained, but there is no doubt that to plunge the patient in a cold bath or tepid bath afterwards gradually cooled down by the addition of cold water is the most rapid and efficient method of treatment that can be devised. Even in puerperal fever may be saved by its means. The duration and frequency of the bath or pack will depend upon the height of the temperature and the influence which it exerts upon its reduction, and also upon the symptoms exhibited by the patient; the general management of the remedy differing in no way from its use in the ordinary continued fevers.

Methyl alone, or in conjunction with the bath or other antipyretics, is of the greatest value, but it must be given with a sparing hand where the symptoms of cardiac failure and general exhaustion call for its employment.

Blood-letting is practically out of the question.

Purgatives have been employed in the early stages, and their antipyretic action is sometimes well marked; 5 grains of Calomel may be given, followed by 4 or 6 drachms of Rochelle Salt.

Warburg's Tincture has succeeded in the reduction of fever heat and all its attendant evils when every other remedy has been known to fail. It can be used in collapse when other antipyretics are contra-indicated. Half an ounce may be administered at one dose, and this may be repeated in three hours again.

Tinctures of Digitalis, Veratrum Viride, and Aconite have been recommended, but the results do not warrant their use in a disease where collapse and cardiac failure are often prominent features. Even digitalis as an antipyretic is useless, except in doses which may seriously tell upon the cardiac muscle. Strichnine injected hypodermically may be relied upon for simple cardiac or respiratory failure.

Salicylic Acid, the purified Salicylate of Sodium, and the Tincture of Eucalyptus Globulus are safe, reliable, and agreeable.

antipyretics, which can be used when Quinine and Antipyrine disagree.

Turpentine has long enjoyed a reputation in the treatment of puerperal fever, and it may be tried with some hope of success in conjunction with the measures already mentioned. The form of capsule is the most agreeable and efficient, and 15 minims may be given every four or six hours. It may also be given by inhalation, the air of the patient's apartment being saturated with it by pouring the Spirit of Turpentine upon the surface of hot water. It may be advantageously given in the form of enema when there is much tympanitis, and in the form of a stupe or fomentation. It is an efficient and agreeable counter-irritant when applied to the tense abdomen.

Beyond the treatment of symptoms as they arise, and the reduction of fever heat when this threatens life, little can be done after the onset of symptoms which prove that the case is one of puerperal fever, save to employ every possible means whereby the patient's strength can be kept up by the most sustaining liquid dietary.

Attempts have been made to treat puerperal fever with Serum prepared from animals vaccinated against streptococci. The results are certainly up to the present contradictory and unsatisfactory, though in this direction lies the hope of future progress. 25 c.c. of the anti-streptococcal serum should be injected as early as possible. The comparative failure of the serum appears to be owing to the number of different varieties of streptococci. It has been almost demonstrated that a serum which is of great prophylactic or curative power against one variety of streptococci is absolutely valueless against another. Velde, to meet this difficulty, recommends the use of a serum prepared from a number of streptococci obtained from different sources; this he calls Polyvalent Serum.

Special symptoms must be met by appropriate remedies. Pain is to be combated by Opium in full quantities, the amount and persistency of the pain being the guide to the doses. Pain, as in peritonitis or pleuritis, may be relieved by poulicing or by hot fomentations, by cold compresses, or by hypodermic injections of Morphia near to the seat of the suffering.

In the peritoneal form of puerperal fever the treatment will be the same as for the general condition, plus such local anodyne measures as the symptoms indicate. Vomiting must be controlled by ice and rectal feeding. Leeching is recommended in these cases, but the result is very questionable in a disease where every drop of blood which the patient possesses is required in the struggle against the septic organisms. The same remarks apply to Calomel and theunction of Mercurial preparations, but there is a consensus of opinion that free Saline purgatives are most beneficial.

These remarks do not apply to cases of pure Puerperal Peritonitis,

where the constitutional disturbance appears to be only secondary to the localised peritoneal inflammation. In such cases the remedies useful in puerperal fever may be administered as Quinine, Opium, Alcohol, cold compresses, or Leiter's Tubes, or the Poultrices, Leeches, Salines, Calomel, and other remedies indicated in Peritonitis (which see, page 685).

Credé maintains that in the soluble Silver Salts we have the most powerful general antiseptics known. He uses a 15 per cent. ointment of Colloidal Silver (Collargol), rubbed into the cleansed skin; and in all septic conditions following delivery, improvement sets in in from three to six hours, and threatened puerperal fever is averted. He uses it in all phlegmons and in simple septicaemia and gives the drug by the veins in pneumonia, typhoid fever, &c.

The question of opening the abdomen and washing out the peritoneal cavity has been solved by experience both in puerperal fever, with peritoneal complications, and in true puerperal peritonitis, and little encouragement can be obtained from a perusal of the reported results. To be of any use in puerperal fever the operation must be done at such an early stage as would cause most men to hesitate recommending it. In those cases where there is a clear diagnosis of an inflammatory attack confined to the pelvis or abdomen, without the constitutional element of general infection, an operation may not only be advisable under certain circumstances, but it may be the only means whereby life can be saved. Removal of the uterus has been recommended (See also the treatment of Pelvic Inflammation, on page 675).

PUERPERAL MANIA.

The prognosis being so good the duration of the attack being generally so short and the chance that in some cases sudden and rapid restoration to sanity occurs, all lead the physician to advise the trial of home treatment before resorting to an asylum.

The most easily managed cases, as a rule, are those occurring soon after labour, and such may fairly be expected to recover within two or three months, or less. Obstinate cases must ultimately be sent to special institutions possessing every administrative machinery for coping with all difficulties in carrying out moral treatment. The first question which may crop up will be the one of suckling. As a rule the mother should not be permitted to nurse her child. In rare cases this may appear so simple and easy that the patient's relatives may insist upon it, but the physician should warn them that dangerous impulses may suddenly seize the patient, and that she should not be trusted with the custody of the infant for a moment, nor should she be allowed to remain alone under any circumstances.

Every possible source of excitement should be avoided though it is very doubtful if the old method of confining the patient naked in a darkened room should be followed. Firmness, stillness, and perfect rest are to be maintained, and the infant should be

removed from the room as soon as the patient appears not to be excited by its removal, and, as a rule, it should be kept entirely away from her till recovery is established, or till she expresses a desire to see it again. One or more good nurses are essential, and the friends should leave the case entirely in their hands under the supervision of the medical attendant.

The ordinary functions must be closely seen to, the bowels, bladder, and stomach being watched, and any indigestion or vomiting, constipation, or retention of urine, should be remedied. The diet should be generous but light, as much milk, good soup, or other liquid nourishment as the patient can be made to swallow being administered at short and regular intervals. Forced and rectal feeding may be necessary. Sleep must be procured, but Opium, Morphia, and Chloral are to be avoided. Sulphonal in 20 gr doses two or three hours before bed-time answers well, but Trional, Paraldehyde, and Hyoscyne may be used.

Ice or cold compresses to the forehead, with a sinapism at the back of the neck, assist the action of the hypnotic. Leeching of the temples and other debilitating measures are to be condemned.

Alcoholic stimulants are, as a rule, to be avoided, but in weak and anæmic subjects, especially those who have had much hæmorrhage during or after labour, a good sound claret may be given with food in liberal quantities. Should any increase of excitement be noticeable after alcohol it should not be repeated, but a tonic containing Quinine, combined with small quantities of Digitalis, may be substituted for it.

Bromides are most valuable in the treatment of the chronic stages where acute exacerbations of excitement occur and Iron in some form or other is generally indicated before the patient's restoration to health. It is needless to say that the condition of the vagina, uterus, and ovaries should receive the closest scrutiny, and any departure from health should be remedied, but the practice of making frequent vaginal examinations is to be strongly censured.

In mania or insanity following prolonged lactation, the weaning of the child should not be delayed, and the chief indications will be a liberal and highly nutritious diet, with alcoholic stimulants, especially good Ale, Porter, or Stout, and judicious moral treatment. The condition of the uterus will demand attention, and as sub-involution will often be found in connection with anæmia, both general and cerebral, the indications will be for Iron in large amounts, with Quinine and Ergotin.

R. Ergotin (Bonjean's) gr. i.
 Ferri Reduct. gr. iii.
 Extracti Nuc. Vom. gr. ʒ.
 Quinine Sulphatis gr. ii. mixc.

Fiat pilula. Mille tales xxxvi. Sumat ʒ. post cibos ter in die et hora somni.

PUERPERAL PERITONITIS—See under *Puerperal Fever* (at page 821).

PURPURA.

In very mild cases of simple purpura the patient may be allowed to move about. His diet should be mixed and very generous, and he should have a mixture like the following :—

R. *Tincturæ Ferri* ℥iv.
 Potassii Chloratis 3j.
 Glycerini ℥i.
 Aquæ Camphoræ ad ℥viii. *misc.*

Fiat mistura. Capiat cochleare magnum ter in die ex aqua post cibos.

As a rule, the use of the above will be speedily followed by improvement. In severe cases of so-called simple purpura, rest in bed is essential and large doses of Iron are still believed to be the best remedy, but in all serious cases and in purpura hæmorrhagica iron is not to be relied upon, except in the anæmic stage following large hæmorrhages.

W. B. Richardson, who described an "aqueous" variety of purpura hæmorrhagica, treated it with fresh animal food, diminished amount of fluids, and frequent purgation, giving at the same time a mixture containing Superphosphate of Iron combined with Peroxide of Hydrogen. In the "scorbutic" variety he advised the same treatment as is indicated in scurvy, and in the vascular variety he relied upon Turpentine.

Where hæmorrhages from mucous surfaces are present the case must be regarded as serious, and absolute rest in bed insisted upon. The air of the patient's apartment must be saturated with the vapour of Turpentine, which is also to be given in the form of capsule (10 minims). Stephen Mackenzie gives 10 minims Turpentine with the same amount of Tincture of Quillina in 1 oz. Cinnamon Water three times a day. This treatment is very successful in the ordinary rheumatic variety. When the hæmorrhage continues uninfluenced Ergot must be given freely. The hypodermic injection of 1 or 2 grains of Ergotin may be resorted to several times daily. The room should be kept very cool, excess of bed-clothing must be avoided, the diet should consist of cold milk and cold beef jellies, constipation and purging are both to be equally avoided. Stimulants are to be given with caution.

According to Muskett, Eustace Smith recommends the following draught every morning or every second morning to a child six years old :—

R. *Olei Terebinthinæ* ℥ij.
 Olei Ricini ℥i.
 Mucilag. Tragacanth. ℥iij.
 Syrupi Limonis ℥ss.
 Aquæ Ment hæ Pip. ad ℥j. *misce.*

Fiat haustus, mane sumendus.

Where the hæmorrhage continues after the use of this draught, he gives a mixture containing 3 or 4 minims of Fowler's Solution and 15 minims of Tincture of Iron, three times a day, freely diluted with water, after meals, to a child of the same age.

Where Ergot fails in controlling hæmorrhage, other agents may be employed, as Acetate of Lead, Alum Gallic Acids, Antipyrine, Tincture of Larch, Sulphuric Acid, or Hazeline, and any of the remedies mentioned under Hæmorrhage. By far the best of these, however, is the Chloride of Calcium given by Wright's method, 20 grs. every three or four hours, so as to rapidly increase the coagulability of the blood. Arcangeli recommends Gelatin injections. Ice and any of the above may also be employed locally where the bleeding part can be reached, as about the nose and fauces. Plugging may be needed. Suprarenal Extract may be used locally, and given internally at the same time.

Nitrate of Silver has been claimed by Poulet to have specific action when given in doses of $\frac{1}{4}$ gr. *ter in die*.

Lusignoli, believing that the disease is microbic, injects Corrosive Sublimate into a vein ($\frac{1}{100}$ — $\frac{1}{50}$ grain).

In the later stages tonics are indicated, and Strychnine is of great value, combined with Quinine, as in Easton's Syrup.

Complications which arise from the effects of internal hæmorrhages are to be dealt with on general principles, and under some circumstances Opium may be needed.

Faradisation of the entire surface of the body is reported as having saved life in severe hæmorrhage from purpura.

When occurring in rheumatism or syphilis, after large doses of iodides, or when undergoing the "raw meat cure," or in scurvy or other conditions, the indications for treatment are clear. The above remedies are only to be relied upon after the cause is removed or combated.

PUSTULE, Malignant—See Malignant Pustule.

PYÆMIA.

Like the treatment of puerperal fever, this form of septic poisoning calls for preventive measures, and in the vast majority of instances preventive treatment is as completely successful as ordinary treatment is valueless in the fully-established disease.

The most rigid antiseptic treatment locally will be required in dealing with wounds and injuries, and absolute cleanliness and

free drainage in all cases where an aseptic condition of the injured part is impossible. Pure air is of vital importance, and ventilation must be maintained; but the overcrowding of patients together in surgical wards will not be sufficiently met by ventilation alone. An abundant cubic air space must be supplied to each case. The wounds must be thoroughly irrigated with antiseptics, and every trace of retained secretion must be washed out in this way, and, by free incisions, giving vent at the most dependent parts, and by the insertion of drainage tubes retention of decomposing pus should be rendered impossible. Tension by these means cannot occur, and the frequent changes of the antiseptic dressings will prevent decomposition in the secretions. (See under Wounds.)

Gentleness in manipulation of skin wounds and in dealing with compound fractures is essential, and it is not necessary to say that sponges, soiled bandages, and every possible source of conveying germs from putrefying pus must be rigorously avoided. The bowels, bladder, and kidneys—in fact, all the excretory organs—should be kept in a state of activity.

Internal accumulations of pus, especially when in connection with inflammation of bone, should be incised freely and early. As for drugs in the prophylaxis of pyæmia, there is certainly some efficacy in saturating the system of the patient with iron.

Many years ago, when the writer was house surgeon and superintendent of a large hospital, he was satisfied that the routine rule which most of the surgeons adopted in putting every case with skin wounds or those for operation upon full doses of Tincture of Iron, had an appreciable effect in diminishing the risks of septicæmia, erysipelas, and pyæmia. This was before the introduction of the antiseptic method, when these affections were common. When pyæmia has once developed its characteristic symptoms, the prognosis is most grave, and little is to be expected from treatment in the great majority of instances.

The question of secondary amputation, disarticulation, or the removal of any suppurating portion of the limb, or of the method practised by Lee of dividing any inflamed accessible vein between the heart and seat of original injury has been tried, and in some instances with success, when the operation was undertaken with promptitude in the very early stages.

The treatment of all wounds should be the same as in the preventive stage, and every local accumulation of matter should be incised as soon as possible, the cavities washed out, and suitable drainage with antiseptic dressings applied frequently.

Abscesses in joints should be opened at as early a stage as possible, washed out, drained, and dressed antiseptically, as in ordinary abscesses. The same remarks will apply to collections of pus in the pleura or pericardium. Every complication must be treated upon general surgical principles, in which the freest and most abundant supply of fresh and pure air is never to be forgotten.

It is certainly worth while to attempt to surround the patient with an antiseptic atmosphere, and the writer has done this by making a muslin coverlet, and having it filled with teased-out oakum or Carbolic tow, which is to be kept on the top of the patient's counterpane. Over this, after a brief period, as it loses its virtue by evaporation, Turpentine, Creosote, Thymol Solution, or Eucalyptus, or other volatile antiseptic may be sprayed or sprinkled from time to time. Much can be done for some cases by diet and medication. The diet should be the most sustaining possible, and liquid nourishment should be pressed upon the patient with the view of sustaining his vital powers to the fullest extent with the hope that, if kept alive for a time, the suppurative process may exhaust itself.

Alcoholic stimulants are valuable, but they must be given with no sparing hand. The writer can recall cases in the pre-antiseptic period which were saved apparently by almost unlimited amounts of Whiskey and Port. Whiskey may be given with the milk, and half-an-ounce every hour is not a large amount when the very serious aspects of the case point to its administration. A full dose given with some hot water at the commencement of the rigor affords relief and often cuts short its duration.

Anti-streptococcus Serum has proved very disappointing, and though some cases seem to improve under its influence it is clear that the serumtherapy of septic poisoning is still on a very different footing from that of diphtheria.

Petersen has suggested the production of an artificial immunity from suppuration, but experiments up to the present have not been encouraging.

"Washing the Blood" has recently been advocated. Large quantities of Saline solution are introduced into the tissues or into a vein at regular intervals. The kidneys are thus encouraged to eliminate the toxins by vigorous diuresis.

Of drugs various antiseptics may be given, and the remarks applicable to the drug treatment of puerperal fever apply here. Quinine in full doses gives best results. The newer antipyretics act upon the temperature with greater certainty and precision, but Quinine appears to be of value, even when it fails to reduce the fever heat. Strychnine and Digitalis will be called for to support the failing heart.

The following combination may be given, it proved valuable in one successful case:—

R. Quinina Sulphatis ℥iiss.
Tinctura Ferri Perchlor. ℥iv.
Potassii Chloratis ℥ii
Aqua Chloroformi ad ℥xvj. misce.

Fiat mistura. Signa—"Two table-spoonfuls to be taken, with as much water, every four hours."

Iron in full doses, is of great value in chronic cases. Salicyl, Salicylate of Sodium, Resorcin Iodoform, Sulphites, Sapo-carbolatex, Permanganate of Potassium, Creosote, Turpentine, Iodine, Iodol, Sabul, and various other germicides have been administered internally as well as used locally, but with results which warrant little hope of success.

In those rare cases which recover, the convalescence is most prolonged and tedious, and the physician's resources will be taxed to the utmost. The writer had one well marked case ending in recovery, the convalescent stage of which extended over at least two years.

PYELITIS.

The treatment of suppurative inflammation of the pelvis of the kidney will depend almost entirely upon the cause, and since this varies so greatly the treatment will necessarily be very variable and the same remedies will seldom be indicated in any two cases, but there are some remedies which may be useful in all cases after the primary cause of the pyelitis has been removed.

Where calculi in the pelvis of the kidney have been the cause of the affection little can be expected till these have been removed (see under Stone in the Kidney), though some relief may be afforded by measures directed to the correction of any abnormal condition of the chemical constitution of the urine. When the affection is secondary to enlarged prostate, vesical calculus, gonorrhœa, chronic cystitis or tumours in the bladder, &c. the removal of the cause will lead to rapid subsidence of the pyelitis. When caused by cancer or tubercle nothing but palliative treatment need be thought of. Occurring during scarlatina, typhus, typhoid, smallpox, Bright's disease, diphtheria, diabetes, scum or purpura, these affections will require appropriate treatment. Certain poisons or drugs, such as cantharides, turpentine, copaiba &c., will cause pyelitis, which for the most part rapidly subsides after they have been discontinued.

In acute cases where the cause cannot be determined or removed, absolute rest in bed is essential and the free administration of bland mucilaginous drinks. Poultices, or hot sitz baths, warm fomentations, or all three combined, may be used to relieve pain. Cupping, after the application of a dozen leeches to the loins, may be necessary. Mild diuretics, like the Citrate of Potash, formed by giving a plain solution of Bicarbonate of Potash in effervescence with fresh Lemon Juice, may be administered, but, as a rule, the use of ordinary diuretics, like squill, digitalis, copaiba, brodiaea &c., are to be condemned, and even buchu, uva ursi, pareira, and triticum, are to be given with caution.

In some cases where the urine is markedly alkaline the mineral acids may be tried but, as a rule, little need be expected from them. Boracic Acid is always safe and sometimes acts satisfactorily.

factorily, especially in those cases, acute or chronic, which have arisen from the extension of bladder mischief along the ureters.

Pain may be relieved by Hyoscyamus in full doses of the tincture in preference to Opiates.

In chronic cases the chief indication will be to diminish the secretion of pus, and to support the patient in every possible way by good feeding, Cod Liver Oil, pure air, improved digestion, change of scene, &c. Stimulants are to be given with caution.

Of remedial agents, next to the removal of the exciting cause, Boracic Acid, in doses of 10 grains three times a day, is by far the most efficient. Unfortunately the patient's stomach soon becomes irritated by it, and when the kidneys are seriously involved it is always rejected.

When severe pain is present, it may be given in the following:—

R. *Acidi Boracici* gr. x.
 Codina gr. ½.
 Sodii Salicylatis gr. x. *misce.*

Fiat pulvis. *Mitte takes* xxiv. *Signa*—"One powder to be administered in half a tumblerful of effervescing Potash Water every six hours."

Urotropine, 10-15 grs. every 4 hours, is said by Keyes to be almost a specific in the acute catarrhal form.

Creosote, in the form of capsules each containing 2 or 3 minims, is of service, so also is Quinine in full doses, 5 grains three times a day, combined with 30 minims of any of the Mineral Acids largely diluted. Sulphide of Calcium has had a reputation in diminishing or checking the suppurative process within the body. It does not appear that it has any marked effect in modifying the suppurative action in pyelitis.

Oil of Eucalyptus offers a much more hopeful result, and it is much less likely to irritate than Turpentine, which is the remedy still recommended by many authorities.

Tannic Acid, Benzoate of Soda, Alum, Iron Alum, Acetate of Lead, Hydrastis, Ergot, Cantharides, and various other drugs are recommended, but their action is very doubtful. Perhaps the best effects after Boracic Acid, Creosote, and Salol, if they fail, will be got by large doses of the Tincture of Perchloride of Iron.

Albarran treats severe cases by catheterisation of the ureter and lavage of the ureter and renal pelvis, using a very weak solution of Perchloride of Mercury or Boric Acid solution. He reports many successful cases.

In some cases the operation of nephrotomy is the only hope of saving the patient, the kidney being incised through a skin wound made along the outer border of the erector spinæ muscle, and thorough drainage established under strict antiseptic precautions.

Where the disease is caused by calculi these are, as a rule, easily removed through the wound after being detected by the finger. (See also under Hydronephrosis, page 427.)

Nephrectomy has been several times performed with success and it should be resorted to in calculous pyonephrosis.

PYELONEPHRITIS.

Arising from similar causes as are at work in pyelitis the suppurative process may attack the substance of the kidney. The treatment will be the same as that already mentioned under Pyelitis.

PYONEPHROSIS.

Where the passage of the ureter becomes blocked, and pus accumulates in the dilated pelvis of the kidney above the obstruction the surgeon need not hasten to evacuate it. There is some hope that if the main line of treatment detailed under Pyelitis be rigidly carried out the purulent contents of the sac may dry up, and the entire organ be transformed into a semi-solid harmless inert putty-like mass, which in process of time may shrivel up into a membranous sac without any vestige of renal tissue in it.

Where the tumour points, or where there is any chance of its emptying its contents into the peritoneal cavity or bowel, it should be treated as an abscess upon general surgical principles and evacuated.

Unless in urgent cases or for diagnostic purposes, aspiration is to be condemned. A free incision with strict antiseptic precautions, should be made at the outer edge of the erector spinæ muscle, mid-way between the crest of the ilium and the last rib. From this wound all accumulations in the pelvis may be evacuated, and calculi or tumours may also be cleared out. A long rubber drainage tube, with a broad flange on it, should be inserted deep into the sac, and the most efficient drainage secured.

If, after a very considerable period, the wound shows no signs of healing owing to the continuance of free purulent discharge before matters get too grave the patient should have the chance which nephrectomy or complete removal of the diseased organ will afford.

PYOPNEUMOTHORAX.

The treatment of this condition will be that of the empyema with which it is associated. (See under Empyema, page 206.)

PYOSALPINX.

Various plans have been suggested for the relief or cure of suppurative inflammation of, or purulent accumulations in the Fallopian tubes. Often through the matter finding its way into the uterus and being discharged relieving the patient permanently of further trouble, the like result may be hoped for before resorting

to formidable operations. When the symptoms are acute, absolute rest in bed, with anodynes and very copious and very hot vaginal injections, are indicated as in acute metritis, which is the cause of this affection in the great majority of cases. These vaginal irrigations must to be efficacious be carried out most thoroughly; 4 pints of water at a temperature of 110° to 120° F. should be injected morning and evening, the external parts being protected from the heat. The hot sitz bath, saline purgatives, and other agents indicated in each case should be employed at the same time. After the acute symptoms have passed off a suitable pessary may so relieve congestion and restore the uterus to position as to afford thorough drainage by keeping the uterine canal and the tube patent. This conservative treatment of tubal inflammation often gives more satisfactory results than surgical measures.

In chronic cases, where the degenerative change in the lining membrane of the uterus has led to closure of the uterine end of the duct, the plan adopted by Doleris may be tried before resorting to laparotomy. The os is opened up by antiseptic tents, the interior of the uterus, and especially its Fallopian orifices, are thoroughly scraped by means of the curette, and antiseptic drainage established after packing the uterine cavity with iodoform gauze soaked in glycerin. This plan is very serviceable in simple catarrhal salpinx.

The plan of using Brandt's massage with the view of emptying the contents of the tube into the uterine cavity is so fraught with danger as to be unjustifiable. In cases where it is certain that the uterine end of the tube is patent this procedure may be practised, but at the best it is of very doubtful value and always risky.

Electricity by Apostoli's method has been extensively practised, but has not maintained the reputation which the earlier reports had given to it, and appears likely to fall into disuse. The Faradic current of tension he uses only in acute cases as a rapidly acting sedative, and the Faradic current of quantity he considers only as indicated rarely in some very chronic cases. For the majority of cases the intra-uterine application of galvanism is indicated, and according to the strength of the current used any effect may be produced from a mere alterative action to thorough and complete galvano-cauterisation. It is this last result which is aimed at so as to cause destruction of the mucous membrane as effectually but more safely than by the curette as just described. The positive pole should be introduced into the uterus at first and the negative only after several sittings. Every 5 days, 5 minutes of galvano-cauterisation, with a current commencing with 50 and reaching 150 milliamperes, may be administered.

Where the above measure fails the operation of vaginal galvano-puncture is indicated. Apostoli says "that almost every salpingo-oophoritis will be amenable to appropriate electrical treatment. It is sovereign in the catarrhal salpingitis, calming in the tuberculous salpingo-oophoritis, and capable of curing certain

purulent forms of salpingo-öophoritis by the establishment of vaginal drainage." The latter result is obtained by burying in the depth of less than half an inch a small sharp steel trochar in the part of the inflammatory tumour which is most prominent in the vagina, avoiding the anterior *cul-de-sac*.

The positive pole should be first employed, and later on, especially when a vaginal fistula is desired, the negative should be employed; a current up to 250 milliamperes may be used. The strictest antiseptic precautions are necessary, and rest in bed is essential.

Skutsch removes the contents of the tube after puncturing with a Pravaz syringe. If the contents are clear and free from pus, he opens the ostium and cuts out of the wall of the tube in its vicinity a small oval piece, and unites by sutures the mucous and serous membranes around the aperture thus formed. In cases of pyosalpinx, he sutures the end of the diseased tube in the abdominal incision.

The tubes may be removed by a small abdominal incision, and in simple cases the operation has been completed without a pedicle. If any of their contents escape, the peritoneal cavity must be thoroughly irrigated and drainage established. Some operators have removed the tubes *per vaginam*, but this is not in many cases of pelvic inflammation possible owing to adhesions; very often both routes must be availed of in the one operation.

When the tubes are bound down in the pelvis by adhesions which would render their entire removal by abdominal section hazardous, the tumour may be aspirated from the vagina, but as a rule this will give but temporary relief, the fluid soon accumulating again. The best practice would seem to be to make a free incision into the tumour from the vagina, and wash out the cavity with a mild antiseptic, and inject afterwards with iodine, establishing drainage when necessary. Sometimes the only course open will be a laparotomy to reach the pus, after which the visceral and parietal peritoneal surfaces being sutured together, continual drainage must be established through the abdominal wound.

PYROSIS—See Dyspepsia.

QUINSY—See Tonsillitis.

RABIES—See Hydrophobia.

RACHITIS—See Rickets.

RANULA.

Upon the whole, the most satisfactory method of dealing with these cysts is to snip out a small window-like piece of the cyst wall and mucous membrane in the floor of the mouth, and pack the cavity with a little absorbent wool soaked in iodine (1 in 20).

strong Solution of Perchloride of Iron, or Chloride of Zinc, with the view of exciting inflammatory action.

The opening may require to be enlarged with the scissors if it closes too rapidly. The writer has treated many small ranulae by simply removing as much of the anterior wall as possible with a fine sharp-pointed pair of scissors, and leaving the gap to close up by natural means. Excision of such cysts is most difficult, and rarely necessary; and the establishment of a permanent fistula is equally difficult in some cases, unless Dupuytren's seton instrument be used. Occasionally the introduction of a horse hair seton is successful. In congenital cases the cyst may be tapped and rubbed with the solid Nitrate of Silver.

RAYNAUD'S DISEASE.

The uncertainty about the pathology of this form of gangrene renders a rational method of treatment difficult. The object should, as far as possible, be to determine the underlying cause of the arterial spasm, and remedy it by appropriate agents. Thus, in the cases where a syphilitic history is evident, the condition has disappeared after the exhibition of antisyphilitic remedies, and where Bright's disease, diabetes, alcoholism, injuries to the abdomen, meningitis, mania, emotional disturbances, exposure to cold, leprosy, &c., are probably exciting causes, these conditions should be met by the recognised remedies. A warm climate when possible, and warm woollen clothing are most important aids, and the digestion and intestinal functions should receive close attention. Barlow in his exhaustive article in Allbutt's System dwells upon the importance of Galvanism. He immerses the affected limb in a vessel of tepid Salt Solution, and drops one pole of a constant current battery into the liquid and places the other pole in contact with the skin of the limb above the water level, using as strong a current as the patient can bear with frequent breaks of contact, the patient being also directed to make voluntary movements with his fingers or toes.

In chronic cases shampooing and Swedish movements are added to this method. The local treatment will depend upon the condition of the affected parts (See Gangrene). In Professor Smith's interesting case the treatment consisted in the administration of 10 grain doses of Antipyrine for the first three days, and afterwards of a mixture containing Arsenic and Strychnine every six hours. Alcohol, Indian Hemp, and Opium give considerable relief.

Vaso-constrictors and vaso-dilators to shut off or increase the blood supply as indications warrant have given unsatisfactory results.

RECTUM, Cancer of—See Cancer.

RECTUM, Inflammation of—See Proctitis.

RELAPSING or FAMINE FEVER.

As the name implies, this scourge is associated with starvation in most epidemics, and the treatment must be chiefly sustaining. Though distinct from typhus, its management may be briefly described as that which would be suitable in a smart attack of that fever occurring in a broken-down patient.

Abundance of liquid and easily-digested food, administered *cautiously at first*. Alcoholic stimulants to be given as indicated by the pulse and collapse, Quinine, for the high temperature, and rest in bed after the fall in the fever, and the steady administration of every sustaining agent so that if relapse occurs, the patient may be well prepared for the further drain upon his vital powers, are generally all that can be done to tide the patient over the attack.

Dysenteric and pulmonary complications are indications for the continuance of Quinine and Alcohol. The drug treatment of this disease has proved a failure; there is no known drug which has any specific action upon it, quinine fails to do good, and the new antipyretics have already been discarded, more importance must be attached to stimulants and food.

REMITTENT FEVER.

The treatment of this affection is to be conducted upon the same principles as are indicated in intermittent fever, the sovereign remedy being Quinine in large doses. In the early stage of the disease, until the recurrence of the first remission proves to the physician the nature of the disease with which he is dealing, ordinary diaphoretics, as Spirit of Nitrous Ether, alone or combined with small doses of Tincture of Aconite, will probably suggest themselves, or moderate doses of Antipyrine may be used. A good purge—5 grains of Calomel—is a favourite dose with those experienced in dealing with the early stages of suspected malarial fevers.

Once the remission has occurred there should be no time lost in administering Quinine, 20 grains should be given in divided doses of 5 or 10 grains inside an hour. When vomiting is severe and incessant, 30 or 40 grains may be given by the rectum, or hypodermically (see under Intermittent Fever). This dose will occasionally be all that is necessary in mild cases, and may effectually prevent further exacerbations; but, as a rule it will be advisable to keep the patient under its influence for some time, and for this purpose some physicians begin with 5 grains, and continue this dose through fever and remission till cinchonism is produced. In the malignant forms of the disease Quinine must be given by hypodermic injection, and smart purging by salines should be resorted to.

Hyperpyrexia, which sometimes occurs in severe cases, will not be met by quinine, and the newer antipyretics or Salicylic Acid are not to be relied upon. In the face of a rising temperature

above 106°, a cold bath or cold pack should be immediately resorted to. Warburg's Tincture is often useful in cases where these remedies are not permitted.

Collapse, vomiting, diarrhoea, intense headache, restlessness, and other complications or symptoms, are to be met by remedies which, under the same circumstances, would be indicated in typhus or typhoid fevers. It is needless to say that bleeding, leeching, purging, mercurialisation, emetics, and other lowering treatments are not to be thought of. Arsenic is of use in the later stages.

RENAL COLIC—See Stone in the Kidney.

RENAL DISEASE—See Bright's Disease, Pyonephrosis, &c.

RETENTION OF URINE.

For the relief of a distended bladder the hot bath and catheter are the appropriate remedies. The history of the case will generally give at once some idea of the cause. Thus in a patient in advanced life with a history of failing power in emptying the bladder, and in the absence of a history of stricture, enlargement of the prostate is almost certain. Here, as already mentioned under Prostate, Enlargement of, page 798, the surgeon should attempt to pass a pure vulcanised rubber instrument of the size of about 8 or 9 (English). The catheter should not be passed till the patient has been placed in a hot bath, and often micturition occurs in hospital cases especially after 20 or 30 minutes in the bath. When the rubber instrument fails, the gum elastic or French coudee may be tried. The writer, after failing with the rubber, generally finds that a large-curved silver instrument is the best in acute cases. With skill and confidence this weapon will seldom fail in entering the bladder. The novice is almost certain to try the smaller sizes, but a No. 10 long (English) silver catheter with a wide curve is the proper instrument.

Regarding the plan for passing it safely into the bladder little need be said, as a little experience is worth volumes of written directions. The catheter should be rendered aseptic inside and out, and it should be well oiled, and the greatest patience and gentleness are essential, and sometimes the introduction of the left index finger into the rectum will greatly assist the passage of the instrument.

Where the difficulty of introducing an instrument is very great, especially when some previous operator has succeeded in making a number of false passages, it will be necessary after its introduction to tie in the instrument for a time (the tying in of a silver catheter is, when possible, to be avoided).

When getting into the bladder is impossible, after reasonable patience has been exercised, and where the patient urgently requires relief, his bladder may be tapped by the aspirator above the pubes—a simple and safe operation, after which often a rubber catheter

can be then passed through the urethra and tied in for several days, antiseptic precautions being attended to. (See under Prostate, Enlargement of, page 799)

Where the retention is the result of stricture, and the history of the case leaves no doubt of the diagnosis, the surgeon should keep clearly before his mind the pathology of this affection. In this lies the secret of successful treatment. A few hours before the attack of retention probably the patient passed his urine freely though in a small stream. The element of *spasm* and *swelling* of the urethral mucous membrane from some recent chill or irritant is the exciting cause, and affords the explanation of the sudden blocking up of the urethral canal.

When time permits, these causes should, if possible, be combated by a *hot* bath and a full opiate before resorting to the use of the catheter.

After the failure of these the patient should be put to bed and a No. 1 or 2 gum-elastic instrument without a stylet should be passed down to the stricture, and with patience and gentleness it may be coaxed through. After the opening up of the anterior portion of the stricture, the writer has often succeeded in passing through a No. $\frac{1}{2}$ or a No. 0. Where these fail a No. 1 silver catheter may be tried, but in inexperienced and rough hands this is a dangerous instrument, as every hospital house surgeon knows. When the bladder is entered and the urine drawn off, the instrument should be tied in, and the greater the difficulty experienced in passing it, the more reason is there for tying in the catheter, so as to avoid farther irritation when the bladder again fills. After a few days a larger instrument may be passed and tied in, and the routine treatment for stricture may be then commenced.

Where the bladder cannot be relieved by the urethral route, it may be punctured with the aspirator needle above the pubes, or a suprapubic opening may be made by a long curved trochar and canula, which may be retained for a few days, or the bladder may be opened by the rectal route, or by the button-hole perineal opening, known as the operation of *Boutonnière*. (See under Stricture of the Urethra, Urinary Fistula, &c.)

Where the retention is caused by a small impacted calculus this should be removed by suitable forceps, or if too close to the bladder, a gum-elastic or silver catheter may be gently worked past it.

Where swelling or inflammation of the urethra, as in gonorrhoea, is the cause of retention a very *hot* bath and a warm urethral injection of distilled water with a smart Saline purge, and, if necessary, leeching the anterior portion of the perineum, may be tried, after which a rectal injection of 30 minims of Laudanum, or the introduction of a Morphia suppository, may be resorted to. In unyielding cases a medium sized soft rubber catheter may be introduced.

In hysterical retention, or in retention owing to temporary

paralysis of the bladder, as in fevers, and after accidents or opium, a soft rubber catheter is the best instrument for drawing off the accumulated secretion. Where nothing complicates the hysteria, the use of the catheter should not be resorted to till moral treatment, the free use of the cold douche, and other anti-hysterical remedies have proved unsuccessful.

RETINAL DETACHMENT.

The treatment of this troublesome affection is most unsatisfactory and tedious. The only cases where any very marked improvement may be confidently expected are those in which the patient comes early under the physician's care, and under these circumstances the course to be pursued is clear. Rest is the one most important and essential element in treatment. The patient should be confined to the horizontal position in a darkened room, with a moderately tight bandage over the eye. Diuretics and Saline Cathartics may be advantageously used, and when the amount of sub-retinal fluid is large a puncture should be made in the outer coat of the eyeball and the fluid drained off. There does not, however, appear to be much benefit from this procedure after the re-accumulation of the dropsy, though when adopted early in large extravasations the results are good.

Pilocarpine in full hypodermic doses has certainly been followed in some instances within the writer's knowledge by very marked improvement. The *full* physiological action of the drug must be induced and the injections repeated daily or every second day for many weeks.

It has been suggested to perforate the sclera behind the detachment by a needle insulated except at the point. After penetration the needle is attached to the positive pole of a battery, the negative electrode being placed below the occiput; a weak current (5 or 6 milliampères) should be used. Terson has used electrolysis in this way in 12 cases, 10 of which were improved and one cured.

The most recent form of treatment is subconjunctival injections of Gelatin dissolved in 6 per cent. solution of Chloride of Sodium. — 3·5 parts of gelatin to 100 parts of the saline solution, and sterilized. Cecil Shaw has tried it in one case with marked benefit.

RETINITIS.

In simple inflammation of the retina, little can be done but to insist upon absolute rest and the exclusion of light, and mild counter-irritation above the brows or on the nape of the neck, and to search diligently for the constitutional affection upon whose presence the retinitis depends and treat it.

In albuminuric retinitis the treatment should be directed to the

condition of the kidney, and the various remedial measures are detailed under Bright's Disease upon page 87.

In syphilitic retinitis small doses of the Perchloride of Mercury after a course of Iodide of Potassium, will afford the best hope of cure or amelioration.

In the pigmentary form the mildest continuous current often does good.

RETROFLEXION AND RETROVERSION — See Uterus, Displacements of.

RHEUMATISM, Acute.

Upon the first symptoms of pain, heat, and redness in one or more joints, with increased temperature and sweating, the patient should be ordered off to bed without a moment's delay. There is, perhaps, no other diseased condition where absolute rest in the horizontal position is more clearly necessary. Endocarditis followed by *permanent* valvular mischief, is decidedly less likely to occur in patients who have taken early to bed after the development of rheumatic fever.

The sick room should be selected upon the ordinary sanitary principles, and it is better that it should not be upon the ground floor. The air of the room should be kept at a uniform temperature, and currents of cold atmosphere are to be avoided, hence ventilation by the windows is not advisable. The dry heat given out by a really good Fletcher's gas stove or a Tait's thermic ventilator is a desideratum. The bed should consist of a good hair mattress upon the top of a hard straw palhassie, feather beds being objectionable, both on account of the patient sinking into them and also because of his profuse sweating. Sheets (especially linen) must be dispensed with, and it adds greatly to the comfort of the patient if he be placed between light or thin flannel blankets. The bed-clothes should not be abundant, and a loose and thin flannel night dress, which speedily absorbs the cutaneous moisture, is to be preferred to calico or cotton. Loosely-fitting drawers of the same material may also be worn. A bed-pan and urinal are essentials. A common pickle bottle makes a convenient urinal.

The diet may with advantage consist entirely of milk, with farinaceous food occasionally, and at a later stage beef tea, soups, chicken jelly, or concentrated beef essences may be administered after the subsidence of joint pains and fever. Latham insists upon the importance of a pure milk diet, and points out that soups and beef essences cause relapses. Other writers do not agree with him in this. Thirst may be relieved by small quantities of ice sucked in the mouth, or by the frequent administration of a wine-glassful of equal parts of iced kal: water and milk, or by lemon juice diluted with three or four parts of water. Alcoholic stimulants are not generally required. Cardiac weakness and various compli-

cations, such as pleuritis or pneumonia, may, under certain circumstances, call for them in full doses.

Of drugs, there is no remedy equal to the Salicylates, and, though some eminent authorities recommend a pure Expectant or Peppermint water treatment, and publish excellent results from its use, nevertheless it is highly probable that these savants would resort very soon to the salicylic treatment should they themselves be unfortunate enough to become the victims of an acute attack of rheumatism, with its unbearable pains and aches.

Those who recommend Aconite, Veratrum Viride, and Cimicifuga have more claim to be heard, and there is no doubt that small doses of these drugs have some influence in modifying the fever and alleviating the joint pains. Two minims of the B. P. Tincture of Aconite, given as soon as the patient comes under notice, and followed up by one minim every 30 minutes for six or eight hours, often afford considerable relief, and in mild cases appear to cut short the attack, but in many cases such treatment fails entirely.

The writer would go so far as to state that, given a typical case of severe acute rheumatism, the physician is not warranted in withholding the salicylic treatment, and, since those who begin with aconite and other agents generally fall back upon the salicylates, it would appear more rational to lose no time, but to put the patient at once under their influence, and save him all the suffering possible.

The literature of the Salicylic treatment since its introduction by MacLagan would fill a small library, and volumes might be made up of statistics attempting to prove its efficacy or its failure in influencing the *duration* of the disease and its effects upon preventing or determining *cardiac complications*. Under the head of Endocarditis these important points have already been referred to and only brief mention can be made of them here.

It cannot be denied that the salicylic treatment affords the most certain and speedy means by which all the symptoms of acute rheumatism may be relieved, but it must be granted that it still remains to be proven that this treatment has the power of cutting short the actual *duration* of the disease to any considerable extent. As regards the effect upon the cardiac complications likely to occur during the attack, it must again be admitted that clear proof is still wanting to demonstrate that it lessens to any appreciable degree the occurrence of endo- or pericarditis.

By closely watching the cases long after recovery the writer believes that it may be possible to prove that of a number of patients who have suffered from rheumatic endocarditis, a smaller percentage of those who had received salicylic treatment will eventually develop *permanent* valvular mischief than of those subjected to expectant or other methods. This is obviously a very difficult point to settle, but of late years the results of hospital and private cases (but chiefly the latter) have led the writer to

gravitate towards a conclusion in favour of the permanent benefit arising from the salicylic treatment.

It does not appear that these remedies prevent relapses, and indeed it would seem upon the contrary that relapses are as anything more frequent than when the Alkaline treatment is alone used. This may be, however, owing to the patient indulging in exercises or movements whilst the pains are in complete abeyance under the influence of the salicylates before the attack has entirely passed off.

The various drugs embraced under the general term of Salicylic remedies include Salicin, Salicylic Acid, Oil of Wintergreen, Salicylate of Soda, and Salol.

MacLagan recommended salicin some still adhere to the acid, but the great majority of physicians rely upon the salicylate of soda, and, upon the whole it is from many points of view the drug best suited to the great bulk of cases. Salol in full doses is dangerous, owing to its high percentage of carbolic acid.

Since Charteris isolated a substance from the artificial acid and its soda salt and experimentally demonstrated it to be the cause of certain toxic effects noticed after large doses of these drugs the salicylate treatment has become universally accepted as the best. Only the pure acid or its soda salt should be used in medicine and much larger doses than those hitherto employed may be given with perfect safety.

30 grains of the purified salicylate of soda may be given as soon as the patient comes under observation, and 20 grains may be given every three or four hours afterwards. In twenty-four hours after the inauguration of this treatment often all fever has disappeared, and the joint trouble may be noticed to have entirely given way. In the writer's wards the students complain that they never see "rheumatic fever," as the symptoms and signs of the disease are, as a rule, entirely removed by the salicylic treatment before they get a sight of the patient.

Some physicians prefer to give 15 grains of the soda salt every hour for four or five doses, then every three or four hours, but each case may be treated upon its merits, and as the temperature falls the amount and frequency of the dose may be diminished. The best plan will be to proportion the size of the dose to the length of time from the commencement of the patient's illness till he came under observation. Thus given a patient ill for several days with many joints affected, it will be well to save time by giving 30 grains of the soda salt immediately, and 20 grains every two or three hours, according to the effect upon pain and temperature. 15 grain doses three times a day should be given for a week after the subsidence of the pain and fever.

Salicin may be given in wafer papers containing 15 or 20 grains each, and a favourite method of administering the pure acid is to give 20 or 25 grains in half an ounce of Mindererus Spirit. The soda salt has a most unpleasant taste when given in ordinary

mixtures containing flavouring syrups or other ingredients, and the best plan is to prescribe it in the form of powders, each containing 15 to 30 grains, to be given in effervescing Potash water. The advantages of this plan are obvious—it is more palatable, and it combines the salicylic treatment with the alkaline. These remedies should be stopped or suspended for several hours as soon as their full physiological effects, as buzzing in the ears, deafness, &c., are established.

Latham insists that the true salicylic acid from the vegetable kingdom should alone be employed, the artificial or carbolic product and its salts, no matter how purified, he rejects. He uses the following formula:—

R. *Acid. Salicylic. Ver.* gr. c.
 Pulv. Acacia gr. xv.
 Mucilag. Acacia q. s. *misce.*

Divide in pilulas xxx.

He brings the patient rapidly under the drug by giving 6 pills every hour for three doses, and if the head remains unaffected he gives a fourth dose at the end of another hour. He repeats the dose every four hours till the physiological effects of the remedy show themselves. Generally 80 to 100 grs. are enough, but in bad cases he gives 150 grs. Afterwards 80 grs. daily suffice.

When the temperature falls 50 grs. may affect the brain. The drug is a true antidote, and the larger the dose of the poison the larger the dose of the antidote required. He gives the patient from 40 to 80 grs. daily for ten days after all pain and pyrexia have passed away.

He insists upon the importance of a daily complete action of the bowels by 2 to 5 grs. Calomel at night, followed by a Saline if necessary. Salvation should not be produced, but in all cases where the salicylic acid has failed to bring down the temperature he found that the addition of calomel made the disease at once run a favourable course, and he states that calomel, followed if necessary by purges, is the best adjuvant to the acid.

Percy Wilde insists upon the reality of acute rheumatism without joint manifestations, and in some instances without fever, basing his diagnosis upon the acid reaction of the skin. He recommends measures for raising the temperature of the body, and he is opposed to salicylates and antipyretics.

Alkalies had been long the recognised remedies in the treatment of acute rheumatism, and it is to be feared that their value is becoming lost sight of since the introduction and general use of their more speedily acting rivals—the salicylates.

It is claimed for them that they act as specifics or antidotes to the rheumatic poison which has long been regarded as an acid substance, and though the progress of pathological research appears

to point in a different direction, nevertheless experience has established the empiric fact that these agents exert a most beneficial effect upon the intensity, duration, and complications of acute rheumatism, and it is affirmed by some that they tend to prevent cardiac mischief to a marked extent.

The Bicarbonate of Potash is the salt generally selected and should be given in doses sufficient to rapidly render the urine alkaline. Thirty grains may be given every three or four hours, and after the effect upon the renal secretion has been thoroughly established, 15 or 20 grains four or six times a day may be given for many days, or even for several weeks till the disappearance of pain and fever indicates that the disease has exhausted itself.

The addition of Citric Acid or fresh Lemon Juice to each dose of the alkali in no way diminishes its good effects, and where a more decidedly alkaline action is desired the Tartrate or Acetate of Potash may also be given.

Garród's plan of treatment consists in giving full doses of Quinine (5 grains) in conjunction with alkalis every three (four or five hours). This is known as the modified alkaline treatment.

The writer's plan consists in full doses of the Salicylates, already mentioned, till a rapid impression is made upon the pulse and joint pains. This occurs generally within 24 hours, after which time the dose of salicylate is diminished by about one-half and a moderate dose of alkali added, the combination of alkali and salicylate being kept up for many days after the disappearance of the fever and joint troubles.

Some authorities insist upon a combination of the two treatments from the beginning, and Luff has satisfied himself that this method gives the best results as regards the percentage of permanent valvular disease. He gives 20 grs. Sodium Salicylate and 30 grs. Potassium Bicarbonate every two hours till the joint pains are relieved, then every four hours till the fever disappears. After this 15 grs. of the salicylate and 20 grs. of the potassium salt, as the case demands.

The Bicarbonate may be given in the form of a strong aerated potash water (30 grains to 10 ozs.), to which the salicylate is added just before swallowing, or 20 grs. of the bicarbonate may be added to half a tumblerful of ordinary potash water, in which 20 grains of the salicylate have been dissolved, or the following mixture may be ordered:—

R. *Sodii Salicylatis* *℥iv*
 Potassii Bicarbonatis *℥vi*.
 Isquor. Morphinae Hydrochlor. *℥iiss.*
 Aqua Camphorae *℥xvi.*

Fiat mistura. Capiat ℥i. quater in die

Or the following plan may be adopted :—

R. *Potassii Bicarbonatis* ℥vj.
Aque Destillata ℥xii. *misce.*

Fiat mistura. Signa—"One of the powders (i.e., 20 grains Salicylate of Soda) to be dissolved in two table-spoonfuls of this mixture, after which an equal quantity of Lemon Juice is to be added, and the whole to be taken during effervescence every four hours."

Lemon Juice alone in large quantities has been used by Owen Rees as a means of treating acute rheumatism through all its stages. It is doubtful if it possesses any specific virtues, but in the form of the Citrate of Potash its utility is established. As the free juice can do no harm, and as it affords a pleasant drink to the patient, it may be freely given, even to the extent of the juice expressed from a dozen lemons daily. This may be administered alone, diluted with water, or better still, mixed with an equal quantity of kali or potash water. In prescribing the various alkaline or salicylic compounds in the form of effervescent mixtures in rheumatic fever, it is advisable to order more lemon juice or citric acid than is merely necessary to saturate the alkali. The recipe given above affords a method of combining the lemon juice, alkali, and salicylic plans of treatment. The citrate of potash resulting from this combination of agents is converted into the carbonate in the system, and increases the alkalinity of the blood.

Iron, in the form of large doses of the tincture of the perchloride, has been advocated by Reynolds and some others, but their results, read in the light of the natural tendency of acute rheumatism to cut itself short or to abort in many cases, do not appear to justify its use.

Antipyrine and Antifebrin have been recently tried, and in some instances have given excellent results, as the reports of Guttman show. The pain and fever rapidly yield to 15 grain doses of the former and to half the quantity of the latter drug. The effects, though more rapid, are less lasting than those obtained from salicylates, and their proper place in the treatment of acute rheumatism appears to be where salicylates fail, and it must be acknowledged that this is seldom.

Where the temperature is high and, notwithstanding the free administration of natural or purified salicylates, it continues to ascend and hyperpyrexia is feared, these drugs or Phenacetin may be given sometimes with benefit after the suspension of the salicylates, but, when hyperpyrexia occurs they are useless. The cold bath or pack must then be resorted to without delay, or otherwise life may be lost.

Iodide of Potassium in full doses (5 to 15 grains), is still recommended by some authorities. The writer has never seen any benefit from the drug in the acute form of the disease but in the later stages it often acts most beneficially. It should be given with alkalies. Free Iodine has been recommended by some authorities.

Methylene Blue has its advocates, though it is more efficacious in gonorrhoeal rheumatism.

Benzoates, Guaiacum, Trimethylamine, Rhus Toxicodendron, Salophen, Propylamine, Lithium Salts, Bromides, Colchicum, Sulphur, Nitrate of Potassium, and many other agents have been used from time to time, but their use is or should be confined to those rare cases where the previously mentioned remedies have failed.

Opium, however, deserves some mention. At one time it was used alone as a method of treating acute rheumatism through all its stages, and the writer has seen it used in 1 grain doses every 4 or 6 hours to cut short the disease and relieve pain. It certainly appears to be most useful when cardiac complications arise and when pain and cardiac distress are present. At any period of the disease opiates may be used to relieve pain and induce sleep without interfering with the action of other remedies. The combination of Opium with full doses of Nitre (30 grains) often gave excellent results in pre-salicylate days.

Salivation, Blood-letting, and Leeching are now only of historic interest.

Blisters were recommended by the late Dr. Harkin in the treatment of acute rheumatism upon totally different lines from those laid down by Herbert Davies, who applied them to the affected joints. In carrying out Dr. Harkin's treatment one large blister is applied over the cardiac area as soon as the symptoms of the case warrant a positive diagnosis of acute rheumatism being made. The writer has seen many cases of the disease treated in this way, and has had the privilege of seeing the immediate effects of the treatment in several of the patients whose cases have been published. In almost all the cases there was a most rapid and remarkable relief of the symptoms, pain in the affected joints sometimes disappearing entirely along with swelling and local and general high temperature. In some cases no return of the symptoms occurred, and an uninterrupted recovery ensued. In others the pains and fever, though lessened, continued, and salicylates with alkalies had to be resorted to. (See under Endocarditis, page 272, where Caton's views are explained.)

Wet packs, hot packs, and Turkish baths have been employed as agents in the treatment of acute rheumatism, but their use requires much discrimination. As a rule their routine administration should be discouraged, or confined to the later stages, or to sub-acute, or chronic attacks. The cold pack, by frequent renewing, may be used as a substitute for the cold bath

in the condition of hyperpyrexia, and the hot pack, if used as a local agent, when applied to the swollen joints, is of the greatest service sometimes in relieving pain and swelling.

Local treatment is of considerable importance, and though mentioned last, it should be seen to from the beginning of the attack. The innumerable lotions, liniments, counter-irritating and anodyne applications, as a rule, should be discarded, and the plan of simply enveloping the affected joints with dry, absorbent cotton wool, held *in situ* by loose, open-texture bandages, is by far the best. It is a great mistake to cover the wool with oiled silk or other impervious dressing, owing to the irritating nature of the cutaneous secretion. It should, for this reason, be frequently changed, and Mitchell Bruce recommends that the part should be sponged over with a warm solution of Bicarbonate of Soda before applying wool. Laudanum, Chloroform, Belladonna, Solution of Salicylates or the Oil of Wintergreen, Ichthyol, and Liniment of Iodine have been recommended.

Stromeyer recommends the application of ice-bags, but the plan has found little favour in this country, and the same may be said of the practice of injecting carbolic acid into the joint, though Zagato reports great relief of pain by tapping and injecting 15 mins. of a 2 per cent. solution.

The most thorough and complete rest of the affected limbs is essential, and sometimes a temporary splint is useful.

Davies plan of blistering the affected joints has been already referred to. A narrow blister, encircling three-fourths of the joint, often affords much marked relief, but since the success of the salicylic or antifebrin treatment in relieving pain, it is seldom called for. Osler passes the Thermo-cautery gently over the painful joints.

In the acute rheumatism of childhood the same principles of treatment are to be carried out. Small doses of salicylate of sodium, combined with full doses of alkalis, effervescing, give best results, and the importance of enforced and prolonged rest is even greater than in the case of the adult.

RHEUMATISM, Chronic.

The treatment of this affection appears to be in as unsatisfactory a condition as its pathology.

Totally different affections are included by many writers under the term chronic rheumatism. Confining the present remarks to those cases of joint trouble where the clinical history, symptoms, and physical signs indicate an arthritic affection, allied to acute rheumatism, the treatment will depend upon the severity of the case and the stage at which it comes under observation.

Constitutional measures are essential in all instances, and when the attack has followed upon acute rheumatism, the remedies which afford relief in that affection may be indicated. Thus, the wearying joint pains may be often relieved by Salicylates and

Alkalies, especially in those not uncommon cases where sub-acute attacks supervene upon very chronic joint ailments.

In treating chronic joint affections of obscure origin, sometimes one can clear up the diagnosis of rheumatism after observing the marked relief afforded by a few doses of the salicylates. Such relief to pain is, however, at the best, transitory. Attention should be paid to the general health, and any error corrected. Thus damp and cold must be avoided, either element is bad, but when both are combined, the disease resists all treatment. Variations of temperature must be guarded against, and when the patient means will permit of his removal to a warm and equable climate he should be encouraged to try the change. His diet should be selected upon the principle mentioned under the head of Rheumatoid Arthritis. Fats are especially indicated.

The various mineral waters as those of Bath, Wiesbaden, Baden Baden, Buxton, Aix-les-Bains, Aix-la-Chapelle, Strathpeter, and Contrexéville are indicated.

Any system of treatment which stimulates the excretory organ and facilitates the removal of waste products does good. Hence some authorities advise the long-continued use of the Salicylate of Soda, with the view of eliminating uric acid and allied products. Ziemssen gives 75 grains daily in one dose.

Bicarbonates of Soda and Potash and the Lithium Salts are recommended upon similar grounds. The best routine treatment for most cases is the Iodide of Sodium combined with alkalies, but it must be continued for a long time, and one 30 grain dose of the Salicylate of Soda may be given at bed-time. This treatment gives good results in those cases, showing abundant deposits of urate in the urine. The following is a satisfactory combination --

℞. *Sodii Iodidi* ℥j.
 Sodii Bicarbonatis ℥iv.
 Potassii Bicarbonatis ℥i.
 Liquoris Fowleri ℥iss.
 Liquoris Sarsæ Co. Conc. ad ℥xxx. *mixc.*

Fiat mixtura. *Signa*—"A small table-spoonful in a claret-glassful of effervescing Potash water three times a day, after meals."

This treatment may be alternated every month with fair doses of Cod Liver Oil and Tincture of Iron, or Quinine.

Sulphur is a drug of unquestionable utility in many cases. The compound sulphur lozenges of Garrod may be freely used, but the writer obtains the best results by combining its local use (page 848 with its internal administration. It may, moreover, be used locally, whilst alkalies and iodides are being employed internally.

A good plan is to give one large dose, a heaped up tea-spoonful, mixed up in orange marmalade along with breakfast every morning.

Ichthivol in 5 to 10 gr doses acts probably by means of its sulphur, and the Onion is also valuable, if freely used as an article of food for the same reason.

Guaiacum has long enjoyed a reputation as a remedy for chronic articular rheumatism, and is one of the chief ingredients in the electuary known as the "Chelsea Pensioner," the other constituents being Nitre, Sulphur, Rhubarb, Mustard, and Honey. In some cases it seems to relieve the joint pains.

Benzoates, Salol, Colchicine Salicylate, or Phosphorus may be tried when the alkaline remedies cannot be well tolerated.

The local treatment is of great importance in some cases, and the practice of insisting upon absolute rest for the relief of the pain in the chronic forms of articular rheumatism has been sadly abused. Many of the worst cases have become so from the prolonged rest to the affected joint, and the first step in treatment in such cases is to begin passive movement. Frastour insists upon the importance of this, even though the movement gives considerable pain. It gives better results, if adhesions have not already formed though the writer has seen success follow where there were extensive adhesions. Passive motion is preferable in most cases to Ling's plan of resisting the voluntary efforts of the patient at flexing or extending the limb, though this is very useful in the later stages. A good plan is to begin the movements whilst the patient is in a hot or warm bath, and this plan is very suitable in cases where the patient finds himself able to exercise the affected joints while lying in the bath.

Massage combined with the passive or active motion, is of the greatest use, and various local remedies may be used at the same time.

Baths of various kinds have achieved great reputation in the treatment of chronic rheumatism, and, as these are carried out at the various mineral water resorts in conjunction with the administration of the different thermal, alkaline, or sulphur waters, much good may be expected from them. At home, Bath, Buxton, and Harrogate, where the Aix douche in combination with massage can be obtained, give excellent results, and the Droitwich brine baths accompanied with massage and passive movement, sometimes restore to usefulness joints which have been crippled for years. The Turkish bath may be used by those who cannot travel and free movement of the joint, with massage of the limb, may be employed in the bath. Where the state of the patient's heart contra-indicates the Turkish bath, the Russian or hot vapour bath, or the hot pack, with local sprays, may be employed. After coming out of the hot wet pack the patient should have a dry pack by being enveloped in a number of dry hot blankets.

Sulphur baths may be useful, but the amount of sulphur con-

tained in even the strongest thermal baths, as at Baréges, Aachen, Aix, &c., is, after all, too trifling to exert any marked therapeutic action. The temperature of the bath is an important factor in such cases.

Mud, Pine, Sand, and other baths are sometimes used with advantage. The mud baths of Kisch, Dax, and Marienbad are the best.

Several authorities speak highly of the value of hot and cold douches made to rapidly alternate (Scotch Douche). Schaller states that many patients, especially with wrist and ankle troubles, may be relieved by this means, coupled with gentle massage. Patients who have been unable to walk for many months may be sometimes rapidly enabled to move about by the Scotch douche massage and passive motion being then applicable when it could not be tolerated before the use of the douche.

The method of surrounding the affected limb with a dry heat of 250° or 300°, produced either by the gas burner or by an electric heat generator, has often given excellent results. (See page 854.)

Electricity is of undoubted value in most cases if properly used. A weak continuous current passed through the affected joint is of more value than a strong current administered for a shorter period. The electrodes should be well moistened with hot salt and water. This treatment can be carried out in conjunction with any of those already mentioned; under it the wearing pains subside, thickening and exudation diminish, and the nutrition of the affected limb improves. Where there is much muscular wasting the Faradic current may be used, or the electric bath as referred to on page 854 may be tried.

Of local applications, counter-irritants, anodynes, absorbents &c., there is practically no end. The best of all topical remedies in chronic articular rheumatism has been in the experience of the writer:—*The R.P. Linimentum Potassii Iodidi cum Sapone*.

This should be rubbed in twice a day, the joint being at the same time exercised, and massage of the surrounding tissues accomplished, after which a light flannel bandage should be applied over which in cold weather a piece of chamois may be habitually worn.

Sulphur appears to come next in value to this, and the writer has used these local applications every alternate 2 or 3 months. The sulphur should be rubbed dry into the skin over the affected joint and neighbourhood, and covered with a thin layer of absorbent cotton wool, kept in its place by a light bandage. There is no doubt that absorption of a small amount of the sulphur does take place. The remedy may be given internally with advantage at the same time.

Alkaline compresses, Salicylates, Rhus, Ammonium Chloride, Arnica, and various other drugs have been recommended, chiefly in the form of watery solutions or local wet packs, but little

benefit is to be hoped from such. Dry warmth, when possible, is better for the affected joints than any aqueous solutions.

Anodynes as Chloroform, Belladonna, Aconite, Veratrine, Menthol, or other local analgesics may be tried in the form of strong spirituous or oily applications or ointments. The friction with which they are usually applied is generally the most beneficial factor. Oleates of Mercury, Morphine, and Cocaine may be used in the same way.

Any form of counter-irritant may be employed from the various blistering preparations of Cantharides to the mild stimulating compounds containing Camphor, Paraffin Oil and Turpentine are often used. As a rule, benefit is to be expected in proportion to the amount of friction employed. Iodine in the form of liniment is useful where the pain prevents friction and massage. It may be applied freely till an effect approaching vesication is produced.

The Oils of Wintergreen, Cajuput, Peppermint, Chaulmoogra, and Cloves may be employed sometimes with advantage.

Acupuncture and the actual cautery have been tried.

The clothing of the patient should be carefully seen to, and here there is a very great difficulty. The writer has satisfied himself that over-clothing is positively injurious, and in some cases would seem to be the cause of the joint affection. When the patient is over-clad continually, the heat-forming mechanism is, to some extent, in abeyance, and when by any chance chilling of the surface of the body does occur the heat centres do not appear to respond sufficiently quickly. What is true in a general sense is also true in the case of local chills, and a joint or limb which is habitually swathed in woollen fabrics is much more liable to be affected by cold in the temporary absence of the usual excessive clothing. Dry woollen or flannel inner garments of open texture, and of the requisite lightness to ensure thorough ventilation and escape of the perspiration, and at the same time protect the surface of the body from variations in temperature, meet every requirement. It is an excellent plan to have pieces of wash-leather, sewed inside the flannel under-garments, where these cover joints or prominences of bone. In this way permanent relief may be given to chronic rheumatism and rheumatoid arthritis of the shoulder, elbow, knee, and acromio-clavicular joints.

RHEUMATISM, Gonorrhoeal.

Drugs have little effect upon this troublesome complaint. In the acute articular form of the disease the first question to settle is the treatment of the gonorrhoea. The best plan to pursue is to cease any strong astringent or caustic injections, and to begin with a very weak solution of the Permanganate of Potassium in warm water (1 gr. to 4 oz.). This may be injected every hour alternately with plain warm water, and the strength of the solution gradually

raised to 1 gr. per oz. Internally Methylene Blue should be given alone or with Boric Acid. When pain and fever run high the ordinary remedies for acute rheumatism may be tried in turn, beginning with Salicylic Acid or the soda salt, and when these fail, as they generally do, the following may be tried in order - Antipyrine, Antifebrin, Salol, Phenacetin, Exalgin, Oil of Wintergreen, and Quinine. This last drug in large doses gives, perhaps the best results when the first-mentioned remedies fail. Alkalies (see Acute Rheumatism, page 847) should be combined with it or given alternately. 8 grs. quinine may be given dissolved in Hydrobromic Acid, or 6 grs. of the Hydrobromate may be administered every 4, 6, or 8 hours.

In the chronic form of the disease, Iodide of Potassium and Alkalies may be given in full doses, but their effects are at the best most uncertain. Quinine and large doses of the Tincture of Iron sometimes succeed when other remedies fail. A large mercurial purge, i.e., 8 grs. of Calomel followed by a dose of Epsom Salt, sometimes relieves pain and diminishes fever.

A mild Mercurial course may be tried in very chronic cases. Absolute rest and all the precautions necessary in acute rheumatism must be resorted to in severe cases. Too often all constitutional treatment fails.

Local treatment will consist in the use of anodynes or counter-irritants according to the acuteness of the pain. Hot fomentations or warm poultices smeared over with the extract of Belladonna may be tried. The various anodyne applications mentioned under Acute Rheumatism, page 845, may be used. The best of these is a liniment composed of equal parts of Chloroform, Belladonna, and Aconite liniments. Splints may be necessary to secure complete immobility of the limb.

A dry blister made to encircle the affected joint will give more relief than any other application, and in very chronic cases this may be applied often. Passive or active movements, massage, friction, and the various remedies recommended at page 847 may be resorted to. Electricity sometimes does great good.

Hot baths are to be tried, and the writer has seen good results from the spirit lamp bath and fumigation of the limb with the vapour of Calomel, or strapping it over by Scott's dressing. The best local treatment short of surgical procedures is to expose the joint to a dry heat of 300° by the gas jet or electric wire appliance, each seance lasting at least half an hour.

Recently considerable advance has been made in the surgical treatment of this most obstinate affection, and the French method has led to brilliant results in many cases. It consists in a free incision into the joint and thorough irrigation of it by an antiseptic solution, free drainage in most instances will be necessary. In this way the deformities produced by ankylosis are prevented or removed.

RHEUMATISM, Muscular.

The treatment of this affection will generally correspond to that of lumbago (which see, page 527).

At the early stages a few large doses of Salicylate of Soda may cut short the disease with rapidity. A very hot bath (106°F) or the Turkish or Russian bath may be given, but, as a rule, dry heat is best. Where a hot water bath only is available, it should be followed by a dry hot pack for an hour or more, and one good massage afterwards, or whilst in the pack, may act with great rapidity. This often suffices to relieve lumbago and torticollis. Where the pain is not speedily relieved by these measures, a hypodermic injection of $\frac{1}{4}$ grain of Morphia should be given. The various anodyne applications already mentioned may be tried, and Chloroform and Belladonna liniments in equal amounts may be applied upon lint and covered with oiled silk, over which a large pad of cotton wool is to be kept in place by a flannel roller. Hot fomentations, poultices, and dry cupping may be tried and a smart saline purge, followed by the alkaline treatment described under Acute Rheumatism, generally succeeds in giving relief.

The continuous current not infrequently fails, but sometimes it acts like a charm. Puncture of the affected muscles by a large needle driven deeply into the tissues often gives relief.

In chronic cases the remedies mentioned under Chronic Rheumatism must be resorted to, the Iodide of Potassium three times a day, with one large dose of Salicylate of Soda at night, being the best routine treatment when given in combination with the Turkish bath, dry or wet hot packing or the application of a dry heat of 250° to 300° F.

RHEUMATOID ARTHRITIS (Chronic).

If treatment be commenced early much may be done for this obstinate malady. In a small percentage of cases the joint troubles may be caused to disappear, but this need never be expected unless the patient can be completely removed from his surroundings and transported to a drier atmosphere, where the variations of temperature are less marked than in this changeable climate—a warm, dry, equable climate being acknowledged on all hands to be an essential factor in successful treatment.

As a winter resort Las Palmas, Algiers, Egypt, and Southern Italy are suitable, whilst in summer Baden-Baden and Wiesbaden and other Continental resorts are popular. In connection with these places the baths are of great importance, but these will be mentioned later on.

Clothing and diet are also of vital importance. As regards the former, the body should be encased in light woollen garments, worn if possible next the skin but overclothing is to be avoided. The writer advises a thin flannel vest and drawers, with a piece of wash-leather inserted inside the fabric next to the skin, over

the large joints, as at the shoulders, elbows and knees. The practice of piling on garment over garment, so as to keep the patient always in a state of perspiration is to be condemned. The foot-covering is not to be neglected, and cork insoles are essentials in wet weather. All undue exposure to cold and damp, it is needless to say, should be avoided, and the patient should be advised, if possible, not to expose himself during the prevalence of east winds.

If the patient's residence is upon a damp, cold, clay soil, he should be strongly advised to change it for one on a dry, sandy, well-drained soil, and when this is impossible he should be advised to sleep and live as near to his attic or as far from the ground level as possible.

As regards diet, everything which tends to improve nutrition must be freely given. No matter which of the various views of the pathology of the affection may be accepted, there is always evidence of serious impairment of nutrition, and this calls for the most liberal and varied dietary. Mixed food—fresh meat and plenty of fresh vegetables—with a very limited supply of malt liquor, or none at all, should form the basis of the dietary.

Celery, eaten raw or stewed, is a popular remedy, and experience proves that there is some truth in the belief, though the writer thinks that the Spanish onion is the best of all vegetables for constant use by the victims of this affection. In Ireland, where the disease is so very common, it is probable that the excessive use of bacon has something to answer for in inducing the disease.

Fats are an important item in the dietary, and above all other foods or drugs stands Cod Liver Oil. It should be regarded not as a medicine, but as a food, and, in conjunction with the Extract of Malt, should be given at the termination of every meal.

In hereditary cases, when rheumatic or arthritic pains first show themselves in the offspring of parents in whom the disease is well marked, this food or drug should be pushed. The writer has seen good results from this remedy even in obese subjects.

Sometimes an impression has been made upon the disease by a prolonged trial of a purely vegetarian diet, but it is a grave mistake as pointed out by Garrod, to treat the disease as if it were a form of gout by the routine exclusion of animal food.

Every error or departure from the normal standard of health must be carefully sought for and remedied as soon as discovered. Thus prolonged mental exertion, worry, super-lactation, menstrual disorders, frequent pregnancies, and renal disease, may be found to be the exciting causes.

Medicinal treatment in the more acute form of the disease may be tried upon the lines laid down in Acute Rheumatism, but, as a rule, the Salicylic compounds are of very little use, certainly of no permanent use whatever. Those writers who report great benefits

from their administration probably do not differentiate carefully between acute or sub-acute rheumatism and rheumatoid arthritis. In the North of Ireland, where this latter affection is seen not rarely in hospital in a more or less acute form, a differential diagnosis may sometimes be made by watching the failure of the Salicylates, which are certain to speedily relieve articular rheumatism.

Alkalies are always of some use, and large doses of Iodide of Potassium may be combined with them for the relief of the pains in the early stages of the more acute cases. Antipyrine and Quinine alone, or in combination with Opium, may be resorted to in such cases.

For the ordinary chronic cases which come under observation only after the disease has existed for some time, there has been a very long list of remedial agents recommended, but if all be excluded save those which have stood the test of experience the list will become a very limited one, and will be made up of the following in their order of merit—Cod Liver Oil (already mentioned as a food), Arsenic, Iodine, Sulphur, Guaiacum, *Actæa Racemosa*, and Iron.

In conjunction with these, and of considerable value, must be bracketed Electricity (the continuous current), Massage, various Medicated Baths and Spas.

Whilst great benefit, and even permanent success, follow the use of these measures in some cases, nevertheless one after another of them may be tried in vain. Generally, however, failure may be attributed to the patient who soon loses faith in remedies, and flies from one quack preparation to another till the joints have become hopelessly deformed.

The writer recommends the steady administration of a combination like the following for many months:—

R. *Liquor. Fowleri* ℥iiss.
 Potassii Iodidi ℥vss.
 Liquor. Sarsæ Co. Conc. ad ℥viii. *misce.*

Fiat mistura. Capiat ℥i. *ter in die ex* ℥ii. *aquæ post cibos.*

This may be given in conjunction with a dose of Cod Liver Oil after dinner and at bed-time.

The Syrup of Iodide of Iron is a favourite preparation, but in the writer's hands it has generally failed. The plain Tincture of Iodine is better, but the syrup may be given in the intervals during which the Arsenic and Potassium Salt have been suspended.

The old electuary known as the "Chelsea Pensioner," containing Sulphur, Guaiacum, Rhubarb, Nitre, Mustard, and Honey, often relieves pain and checks the progress of the disease. (See page

301, 7th Edition of "Pharmacy, Materia Medica, and Therapeutics."

Actæa Racemosa, in full doses, often affords some relief. Ringer thinks it acts best in those cases where the uterine functions are disturbed.

The continuous current (15 to 25 Léclanché cells), used twice a day in conjunction with any of these drugs, is of much service. The sponge electrodes being well moistened in hot salt and water one is placed just above the affected joint, and the other over the skin at any part of the limb lower down. The induced or interrupted current has been found useful, and Lewis Jones strongly recommends the electric bath using alternating currents from the induction coil or an alternating dynamo-supply with the view of producing general electrification in order to change the nutrition of the entire system. Monbonoff lays stress on the value of exposure to the Electric Light, using the electric arc (25 amperes and 50 to 60 volts) apart from the heat produced.

Recently much attention has been directed to the so-called "Electric Bath," where a portion of the body is enveloped in an appliance by means of which an intense degree of dry heat (200° to 300° F.) is produced by an arrangement like that used for the electric cautery. It is needless to say that this is but a modification of the older plan of applying dry heat by means of the Bunsen's burner, and has no electric therapeutic action whatever. It has been often followed after half to one hour, by considerable relief to joint pains and great improvement in the mobility of the affected joints.

Massage often proves valuable, especially in those cases where walking exercise is painful or impossible, and it may be employed along with the use of electricity, but its best results are obtained when it is carried out in the Turkish bath by a skilful operator.

In very chronic cases it is sometimes astonishing to observe the good which may follow simple passive movements of the affected joints, and by this procedure deformity, pain, stiffness, and ankylosis may disappear, even in bed-ridden patients. It is remarkable to find how little pain and inconvenience some patients suffer from the use of joints, the seat of well-marked changes in this affection, whilst others suffer considerably on movement of joints that appear to be but slightly altered. The writer has seen the pain, stiffness, and ankylosis disappear in some joints after systematic passive movement, whilst the disease progressed in other joints.

Amongst baths, the warm, Sulphurous waters are especially to be commended, and various other saline baths are of undoubted value. Harrogate, Buxton, Bath, and Strathpeffer have their advocates. Aix-la-Chapelle, Aix-les-Bains, Wildbad, Franzenbad, Baden-Baden, Wiesbaden, Pyrmont, and many other Continental waters are of great value. The hot brine baths of Droitwich, with massage, are, in the writer's opinion of the greatest service in many cases, and the good effects may be kept up when the patient

returns by the steady use of the Turkish bath at home during the winter months.

This treatment is of service where all the joints are involved, but the best results are seen in those cases where a limited number of the large and medium-sized articulations are affected.

Hot douches (especially the hot Sulphurous douche, combined with massage), cold douches, mud or peat baths, or the bath made by enveloping or burying the affected joints for one or two hours daily in very hot sand, have been recommended, and after their use, passive movements or massage may be tolerated, when these agents were before contra-indicated by the amount of pain and distress produced by the friction and motion.

Of local applications for the relief of pain there is practically no end. Every known form of counter-irritation has been tried, and any application which is capable of causing an increased flow of blood to the skin may be used. Blisters occasionally relieve pain, and Spender advises that when they are used they should be applied upon the cardiac side of the joint. Most of the good which has been experienced from local remedies has been the result of the friction and massage associated with their application.

Capsicum Ointment, Turpentine, Paraffin Oil, Camphor, Ammonia, Cajuput or Eucalyptus Oils, the Official Liniments of Soap, Ammonia, Compound Camphor, Croton Oil, Iodine, Mustard, Turpentine, or Acetic Turpentine, may be employed. The Liniments of St. John Long and Stokes are popular remedies. Arnica should never be used.

Of local anodynes for the relief of pain, when this is very severe, the Liniments of Chloroform, Belladonna, and Aconite in equal proportions applied upon lint and covered with oiled silk is one of the most efficacious. The joints may be wrapped up in a thick layer of absorbent wool, and covered with thin mackintosh, kept in its place by a moderately tight bandage.

New flannel, dusted over with Flowers of Sulphur, is a popular and valuable remedy when used as a bandage to envelop the affected joints. Chaulmoogra Oil, Cod Liver Oil, Olate of Mercury and Morphine, and other agents have been used in conjunction with massage, or strapping of the joints with stout plaster.

Where local remedies fail to give relief to the wearing pains of chronic rheumatoid arthritis, Opiates, Antifebrin, Antipyrine, Exalgin, large doses of Bromide of Potassium, Colchicum, Lithium, Salicylate of Soda, and Quinine Salicylate, may be tried if the previously-mentioned internal remedies have failed. Colchicine Salicylate, in the form of capsules containing $\frac{1}{16}$ gr. Colchicine dissolved in Salicylate of Methyl, often affords considerable benefit, 6 to 8 may be taken in the day.

Where the hip or knee is involved much relief may be obtained by a Thomas's hip or knee splint, or a steel apparatus may be

adjusted to a leather pelvic girdle with hinge joints opposite the hip, knee, and ankle.

RHINITIS—See under *Ozæna* and *Oatarrh.*

RICKETS.

The treatment of this affection is largely a question of diet and environment; it is therefore the duty of the physician to minutely investigate every detail of feeding and everything connected with the sanitary surroundings of the child, and to have any violation of the laws of health promptly rectified.

A too rigid adherence to some one particular artificial food may be the cause, and a change in this direction may be imperatively necessary. The physician must bear in mind the sometimes marked peculiarities which exist in young children, and any hard and fast lines for feeding must be considerably relaxed. One infant will thrive upon the milk of a cow, which will be poison to another and apparently a stronger child. Patience and discrimination in this matter are, therefore, of the greatest importance at the very outset.

At a glance it is evident that the error in diet lies in the fact that some constituent or constituents essential to healthy nutrition are absent in the rachitic dietary. Various opinions have been held, and still are held upon which of the essentials is wanting. The absence of lime salts, proteid, and carbohydrates have all in turn been blamed. The solution of the difficulty is not made easier by the knowledge that the milk of a healthy mother contains proteid, fat, and salts in such proportions as absolutely prevent the possibility of rickets, and that when cow's milk or other substitute is used instead, with such additions as are necessary to make it identical in composition, rickets supervenes sometimes.

This latter result, however, never occurs unless there be some disorder of digestion, and it may be accepted that a diet consisting of proteids, carbohydrates, and fat, with salts in the proper proportions present in human milk, will cure or prevent the disease in children whose digestive functions are working properly.

The common error is to be found in the absence of fat and diminution of proteid in the diet of children fed upon cow's milk. The cow's milk contains enough fat for all practical purposes, and quite too much proteid, but the digestive troubles induced by the large amount of casein prevents the digestion or absorption of the fat as well as the proteids. If it be diluted with water so as to make the amount of proteids equivalent to that in human milk then the amount of fat will only be about half what is necessary, and the proportion of sugar will be even less.

The obvious treatment which will give the most certain result is to put the child to the breast of a healthy wet nurse, and where this is possible practically nothing else will be required. Failing

this the addition of enough cream and a little beef juice will meet the case, but as a rule it is better to permit the proportions of fat and proteids to remain undisturbed in the cow's milk and to predigest it or pancreatise it. In this way the disease can, for a time, be prevented or cured, and gradually the predigestion can be less and less complete till the infant's stomach is enabled to assimilate cow's milk and water or barley water in the proportions of 2 to 1. A little cream must be gradually added and beef juice given occasionally, and by the time the child is about 9 months old farinaceous food and bread and milk (boiled) may be given. If rickets appear in an infant at the breast, which is rare, the same treatment must be resorted to.

As regards artificial foods, the less they are used the better, and the feeding of children on sterilised cow's milk and peptonised milk and foods for long periods is most objectionable. Pasteurisation is much less liable to lead to rickets, and as a rule, even with very young children, cream and raw meat juice should be a routine to supplement the ordinary cow's milk, chicken soup, egg albumin or yolk, and whole wheaten flour, and a little fresh vegetable juice, as in strained mutton broth, should be occasionally administered. The mistake is more likely to be made in the direction of exclusion.

The more varied the food the better, provided it can be digested. A good mutton broth, with the excess of fat removed and all the vegetables carefully strained out by passing it through a fine sieve, is the best compound for the children of the poor. Much has been written against farinaceous or starchy foods, which is probably incorrect; nevertheless, they should be used sparingly. Exclusive feeding upon these substances must be condemned, and the younger the child the more serious does such a mistake become.

The food upon which the cow is being fed which supplies the milk is of vital importance, and it is the point which is generally overlooked. The practice of feeding cows upon the distillery refuse so freely used for this purpose in large cities is a serious matter, especially when we find that this form of food is often in a stage of incipient putrefaction, and it is sometimes unscrupulously used to the exclusion of sound fodder in order to increase the yield of milk. It always diminishes the proportion of fat.

Plenty of sunshine and pure air are essential to the patient, as they are necessary also to the nursing mother or to the animal supplying the milk for consumption by the rickety child. Cold and damp are to be avoided.

Muskett, who has recently drawn the attention of the profession to the appearance of rickets in Australia, finds the same causes at work as in the old centres of civilisation. He lays great stress upon the necessity of a raw meat diet, with cream. He advises a child ten months old to get 2 oz. raw meat pulp daily, fresh boiled

milk diluted with barley water, and entire wheat flour, as recommended by Cheadle.

Warm woollen clothing and occasional bathing must be insisted upon. A warm salt-water bath, in which seaweed has been infused may be used with advantage in the absence of acute symptoms, and it is a good practice to sponge the child down with tepid or almost cold water while standing in the hot or warm bath. It is necessary to see that the child be not permitted to kick or push off his bed-clothes at night, as chills are often caused in this way; he should be clad in a light woollen sleeping combination suit.

The question of the amount of exercise to be permitted is a difficult one, and the physician must be guided by the amount of bone deformity. Perhaps it is correct to state that mistakes are too often made by compelling children to remain in the horizontal position for long periods, to the detriment of their general health. The writer gets a padded board, to which the child can be secured by broad straps as he lies upon his back; this board, with the attached child, can be carried in the nurse's arms, laid in the cradle or upon a bench in the open air, or upon a table or well-carpeted floor. The influence of the weight of the body is increasing the deformity may be easily exaggerated. It may be wiser to enforce rest more rigidly in the case of female children with the view of guarding against pelvic narrowing, but it is of the utmost importance that such rest shall not confine them to the house, but, on the contrary, enable them to spend every available hour in the sunshine and open air.

The vast majority of cases of rickets recover without leaving any appreciable deformity, and this fact should be borne in mind in the management of mild cases. Well-padded, soft splints may be used where there is much bending of the legs.

Many drugs have been recommended in rickets, about the utility of which very adverse opinions are held. There is one, however, about which all observers are agreed. Cod Liver Oil is undoubtedly of the greatest value. Dawson Williams states that it may almost be regarded as a specific; its value is obvious since, as previously mentioned, the great factor in the treatment of rickets is a diet in which animal fat is the prominent feature. It may be given freely provided it does not interfere with appetite and digestion. The combination, with Kepler's Extract, is always to be relied upon. In bad cases, associated with much wasting, the oil should be used externally as well, and too much cannot be said for the method of using the abdominal roller with friction and Cod Liver Oil, as already described upon page 578.

Tonics (Iron especially) are useful in most cases, and the Syrupus Ferri Phosphatis Compositus (Parrish) is the most popular of all these drugs. Various other syrups containing Calcium are largely prescribed, but it is held by many to be exceedingly doubtful that lime is of any use in this disease. The

Large doses of the Lactophosphate often recommended must be sometimes injurious. Large quantities of lime salts are thrown out of the body in rickets, but it is hardly possible that the phosphate administered can take their place in the system. Though it does not act as a restorative, it may exert some influence on nutrition by its action upon the nerve centres.

Phosphates of Iron and Calcium and Phosphoric Acid are often given upon the supposition that they supply phosphorus to the affected bones. This is, of course, a mistake. These bodies remain as phosphates in the blood, and do not exert any of the marked effects of free phosphorus.

Free phosphorus has of late years been much used in the treatment of rickets, and there cannot be any question of its marked effects upon the growth of bone.

Wegner demonstrated that small quantities of free phosphorus stimulated and altered the growth of bone when given to healthy animals, so that the cancellated structure became hard, compact bone; and in the case of fowls the shafts of the long bones become solid cylinders of dense osseous tissue. Kassowitz found that when given in rickets, even of the most advanced type, speedy recovery always resulted, the bones becoming hard in four weeks in most cases. Numerous observers have confirmed these very striking results. Hazard's solution as devised by Thompson consists of the following:—

Phosphorus 1 grain (or 0·0648 grammes)
Absolute Alcohol 350 minims (20·65 cubic centimetres)
Glycerin 2 ounces (56·79 cubic centimetres)
Spirit of Peppermint 10 minims (·59 cubic centimetres).

Five minims of this solution may be given to a child 3 years old. Double this dose, in the opinion of Berg, should not be given, and the danger of inducing degeneration of the liver cells must not be forgotten.

The writer prefers the following simple formula to all others:—

R. *Olei Phosphorati* (B.P.) m℥i.
Olei Morrhuæ ad ʒvj. misce.

Signa—"One tea-spoonful for a child one year old, to be given after food, along with an equal quantity of fresh cream."

The writer's experience of the phosphorus treatment of rickets is too limited to make an expression of opinion from him of any value, but whilst he has no doubt of its great efficacy in cutting short the disease, he thinks it may possibly be found to be open to serious objection. Considering the experimental results of

Wegner, who has demonstrated the condensation and hardening produced in bone by its use, and remembering that the great majority of cases of rickets recover on improved diet and cod liver oil, without leaving any permanent deformity, it does seem possible that phosphorus might determine the setting of the bones permanently in their deformed condition. This conclusion, however, based upon theoretical considerations, and is not arrived at by clinical experience. The writer is slow to recommend phosphorus in the acute or early stage, though Dawson Williams is satisfied that it is of service in the acute stage in fat children who suffer pain and perspire freely.

Cheadle states that he has no experience of the value of the phosphorus treatment, the results of the dietetic treatment and improved hygiene being so satisfactory that he finds no other measures necessary.

The local treatment, after the subsidence of acute symptoms, will consist in the cautious use of Massage and Galvanism. Intestinal and pulmonary catarrhs should receive early and prompt attention when they arise. The treatment of the permanent deformities is to be carried out upon general surgical principles by osteotomy, osteoclasis, or excision, or by suitable mechanical appliances.

The so-called cases of "Acute Rickets" are really cases of *scurvy*, occurring alone, or in rickety children, and the treatment will consist in fresh lemon or orange juice, with improved hygiene and plenty of sunlight, and attention to the state of the softened or fractured bones. (See under Scurvy)

When the disease occurs in conjunction with syphilis, which is very frequently the case, mercurials in conjunction with improved hygiene and the free administration of animal fats must be resorted to.

RIGOR.

Though no treatment will be of any use unless it succeed in combating the cause of the rigor, nevertheless the condition of the patient can be made much more endurable by a few simple measures.

Following up the natural instinct of the patient, who generally has a marked desire to get as near to the fire or any convenient source of heat as possible, the physician should insist that he take immediately to his bed, where he may be surrounded by dry warm blankets, hot water bottles, and excess of clothing. Stimulants may be freely given. One full dose of Brandy or Whisky should be administered as soon as possible. It is advisable to give this with some very hot water and a little sugar. When the heat has been brought to the surface of the body the excessive clothing may be gradually removed.

Of drugs, Nitrite of Amyl and Chloroform sometimes markedly cut short the attack; but, upon the whole, it is advisable to main-

tain a position of neutrality, and await further symptoms. Quinine often prevents or modifies the severity of recurring attacks; but, owing to its slowness of action, it has no effect whatever upon the rigor if administered during its presence. It is of most value in the rigors of pyæmia. The newer antipyretics do not give any more satisfactory results. The old-fashioned plan of giving a speedy emetic at the very outset, when this is feasible, sometimes appears to modify the severity and duration of the rigors which usher in acute inflammatory or zymotic affections. When there is much constitutional excitement or apprehension on the part of the patient, a hypodermic injection of Morphia often is of great benefit. It should, however, be used with caution if renal disease is marked. In the rigors following the use of the catheter, if given immediately upon the first feeling of chilliness, the rigor may be prevented.

RINGWORM—See Tinea.

RODENT ULCER.

The treatment of this obstinate affection should be that indicated for epithelioma. Constitutional remedies are worthless, and removal of the ulcer affords the only means of checking or curing the disease. Where circumstances permit, complete excision by the knife is, upon the whole, the most satisfactory, and the new surface left may be covered by a Thiersch's skin-graft after hæmorrhage has been arrested. In this way the subsequent mark will be greatly diminished, and healing will be complete in about a week. Sometimes however, the situation of the ulcer renders a cutting operation difficult and incomplete, and sometimes the patient will submit to the destruction of the growth by means of caustics, when the use of the knife will not be permitted. A third method, which gives the best results in large ulcers, is available by combining the knife and caustics, and by this combined plan of operation extensive and deep ulcers may be permanently destroyed, which otherwise would be beyond the reach of surgery. The cautery may be sometimes used instead of the knife.

In the use of the knife it is necessary to go wide of the ulcer, leaving a perfectly healthy floor and margins.

When caustics are to be used, the operator has the choice of Chloride of Zinc, Vienna Paste, Potassa Fusa, London Paste, Arsenic, Nitric Acid, the Acid Nitrate of Mercury, Salicylic Collodion, &c.

The most satisfactory of these is the first mentioned. By attention to details the limits and depth of its destructive action may be counted upon with comparative certainty. The writer has used it many times in the treatment of this affection occurring in the practice of the late Professor Gordon, and always without any mishap, even when the ulcer had crept into the orbit. The Chloride may be mixed with three-parts of wheaten flour, and in

this condition it may be spread dry in an even layer upon the ulcer. If the surface to be destroyed is not a freely secreting one the powder may be made into a stiff paste with water, and spread in a layer as thick as a half-sovereign. The surrounding tissues may be preserved by means of Plaster of Paris, but this is seldom necessary. The paste may be left *in situ*, but about the face it is better to remove it in two or three hours, and re-apply it again as soon as the slough has separated. In this way the depth of its destructive action can be regulated almost with the precision obtainable by the use of the knife.

In the destruction or extirpation of deep and wide ulcers by the knife, if the hollow bones of the face or orbital cavity have been invaded, the combined method is the only one available, the Zep. Paste being carefully applied to the recesses of the knife wound. In some cases the actual cantery, the thermo- or galvano-cautery may be used. Occasionally in the early stages of rodent ulcer the milder treatment applicable to lupus may be successful. The after-treatment of the ulcer is to be conducted upon general principles.

ROSEOLA.

The treatment of this mild affection may be carried out upon the lines indicated under Erythema, page 294. A mild diaphoretic following a Saline purgative, and the use of a warm bath containing a little Alkaline Carbonate, and in severe cases the anointing of the skin by a bland oil or by tard are all that are generally necessary.

ROTHERN.

The treatment applicable to a very mild attack of measles may be carried out in most cases of German measles. (See page 336) The patient will require little medication, save the diuretic mixture mentioned upon page 558.

ROUND WORMS—See *Ascaris Lumbricoidea* (Page 59).

RUBEOLA—See Measles (Page 336)

RUPIA.

The treatment of this affection will simply resolve itself into the treatment of the disease of which it is one of the varied manifestations—syphilis. There are only two drugs of any known value and these are Mercury and Iodides. Rupial eruptions, according to Hutchinson, usually occur after mercury has been given in the treatment of syphilis in too large doses, and has disagreed and been wholly laid aside for some time. Donovan's Solution, internally, may be given, and though sometimes in these cases the Iodide of Potassium or Sodium may give excellent results, as a rule mercury will be necessary. When this drug is given in rupia

the dose should be small, and the administration must be continued for a long period, but the constitutional effects of the drug are to be avoided. Sometimes it will be found advisable to suspend the mercury for a few weeks, during which large doses of the iodide may be tried. The writer saw a most intractable case of rupial ulceration which had resisted all treatment in the wards of Professor Fournier till he tried the hypodermic injection of Dog's Serum, as recommended by Professor Richet; most marked improvement rapidly set in. The general health of the patient is a matter of vital importance, and the diet must be of the best possible. Change of scene, and, if feasible, an ocean voyage may be desirable.

Locally, little need be done in most cases, as the crusts fall off after the ulceration heals under the influence of the mercurial-iodide course, and it is not advisable to disturb the crusts or interfere with them in any way.

Where ulcerated surfaces are found, in spite of this treatment, an ointment of Iodoform, or the Red Precipitate Ointment, will be the best dressing. The fumigation bath, with the vapour of Sublimed Calomel, sometimes acts very satisfactorily.

SACRO-ILIAC JOINT DISEASE.

The treatment will be based upon the general principles laid down for knee-joint and hip-joint affections upon pages 491 and 417. Thus, absolute rest to the affected surfaces must be rigidly maintained for a long period. In children this can be effected by a double Thomas's splint and plaster bandage, in adults a large leather splint may be moulded to the pelvis and leg. Abscesses should be opened as soon as their presence is demonstrated, and if these fail to heal, all sinuses may be opened up and any diseased bone removed, and the cavity scraped and thorough drainage established. The constitutional remedies and general directions as to diet, environment, &c., apply to this affection, and its constant tubercular nature will suggest many of the agents mentioned under Phthisis and Tuberculosis.

SALPINGITIS.

The treatment of inflammations of the Fallopian tube is in the main the treatment of Pelvic Peritonitis, Ovaritis, and Endometritis, and will be found under these headings. The special treatment of suppurative inflammation of the tubes will be found detailed under the heading Pyo-salpinx upon page 830.

SARCINÆ.

The treatment of these microscopic fungi simply resolves itself into the management of the primary gastric affection, which is fully dealt with under the headings of Dyspepsia and Cancer of the Stomach.

SARCOMA.

Under Cancer, upon page 113, the results of the treatment of growths of this nature by injections of Toxins obtained from cultures of streptococci are detailed. See also under Erysipelas, page 291. The most recent reports are not satisfactory.

SCABIES.

The use of almost any one of the innumerable parasitocides will kill the acarus and its ova, but the most harmless to the patient and the one most certain and cleanly in its action, is Sulphur when properly used. The speediest cure is Viemington's Solution by means of which a sharp attack of itch may sometimes be removed in a few hours. This solution is prepared by boiling Lime or Lime Putty with Sulphur in a large quantity of water and after the sediment subsides a brilliant clear yellow solution remains which is the remedy under consideration.

The proportions of the ingredients are of little matter, as it is well to have them in excess, and the water will only dissolve a small amount of the Penta-sulphide of Calcium. 8 oz. of Sublimed Sulphur and 4 oz. of Slaked Lime will make a gallon of the fluid, and with this a large school of children affected with scabies may be cured in a few hours. All that is necessary is to take a small sponge and swab the solution freely into the skin. As the liquid comes into contact with the organic matter contained in the secretions of the skin it gives off free sulphuretted hydrogen and leaves a fine powdery residue, filling up the furrows on the cutaneous surface. The patient may have a previous hot bath with soft soap, scrubbing is not necessary, and hence sometimes little irritation is caused by the remedy, but when there is already much traumatic eczema present, and where the liquid is rubbed in or applied frequently, it may produce considerable irritation.

Immediately after its use the patient may put on his clothes, when the excess of the liquid will cause destruction to any wandering male or young female insects adhering to them, but upon the whole it will be safer to fumigate the clothes and bedding by burning sulphur in the room or by baking them in a hot chamber.

It is well to make several applications to ensure complete destruction to any young which may have escaped the action of the liquid, owing to their deep position in the burrows.

Powdered or sublimed sulphur may also be applied in its dry state, and well rubbed into the skin and sprinkled over the inner surface of the flannel or woollen under-garments. It can be rubbed into the hands and between the fingers, after which a leather glove may be worn. This method, which is cleanly, is not at all so efficacious as the solution.

The oldest and, perhaps, the surest of all methods of using sulphur for the treatment of scabies is to give the patient a good hot bath, in which the body is to be thoroughly scrubbed with a hair brush and soft soap, so as to open up the burrows of the itch

insect, after which Sulphur Ointment is to be rubbed in for several minutes with the palms of the hands into every part of the cutaneous surface, except the face and scalp.

This can be best done before going to bed, the patient sleeping in a combination dress. In the army, after the bath, scrubbing, and rubbing in of the ointment, a blanket, smeared over with the ointment, is wrapped round the patient's body.

The writer has not used the ointment for the last 20 years, and has never seen a case which did not yield to the solution after a few applications. It is a good thing to give the clothes a short baking in an oven or disinfecting chamber. It is said to kill the ova, but these probably never get upon the clothing.

The innumerable formulæ, containing Peruvian Balsam, Storax, Tar, Paraffin Oil, Copaiba, Stavesacre, Green Soap, Cocculus Indicus, Creosote, Phosphorus, Oils of Cade, Cajuput, Anise, &c., are wholly unnecessary.

After the destruction of the insect it may be necessary to treat the eczema and irritation, partly the result of the parasite, and partly the result of the remedy: some bland unirritating ointment, lard, or oil easily accomplishes this.

SCALDS—See under Burns (Page 109).

SCARLATINA.

Under the head of Measles, upon page 556, the diet, selection of a sick room, and other details of importance are mentioned, which are equally applicable to scarlatina, and need not be here mentioned. Owing to the highly infectious nature of this disease, the sick room should be as isolated as possible, and a sheet dipped in Carbolic Lotion (1 in 100) should be fastened outside the door with the view of cutting the room off completely from the rest of the house. This will also keep the air of the sick chamber quite sweet.

It is not advisable to permit baths at this stage, especially when the rash is ill-developed. At a later period their use is indispensable. The bowels should be relieved with a smart Saline as early as the case comes under observation.

Numerous drugs and systems of treatment are still recommended with the view of cutting short the fever and destroying the microbe upon whose presence the disease is believed to depend.

The writer cannot say that he has found any such specific action in any of these agents. Some of them are positively dangerous if given in full doses, and, as a broad rule, it is still to some extent true that "Scarlatina is dangerous only through the officiousness of the physician."

The writer was tempted once to say that it might be accepted as a general truth, to which there were not many exceptions, that

a mild case of scarlatina needed no medical treatment, whilst the really malignant cases were generally beyond the reach of any treatment.

Nevertheless in the management of this disease, its complications and sequelæ, there is often wide scope for the skilled therapist.

The treatment may be divided into two distinct parts—viz, the guiding of the patient through his attack and the prevention of complications, and the means by which the disease may be prevented from spreading to other members of the same household. In cases evidently mild from the beginning the preventive treatment is obviously the most important, and this is more true of scarlatina than of most other contagious diseases for the simple reason that the mortality falls greatly with the age, and if a child can be shielded from infection as long as possible, his attack will probably be milder when the inevitable does overtake him in after years.

The importance of isolation and of scrupulous nursing is obvious, and it must be pointed out that the popular notion is wrong—that the most infectious period is during the later stages of desquamation. The disease is undoubtedly very infectious in the early stages when the rash and fever are at their height, and the virulence of the germs is most remarkable, the spores retaining their virulence for years.

The most popular preventive of the spread of the disease germs is the anointing of the body with a weak Carbolic Oil (1 in 50). This may be commenced from the first, and if such an application fail to destroy the germs, it will effectually prevent the spread of the fine epithelial dust containing them; an Oil, 1 in 25 may be freely used afterwards when desquamation sets in. The free use of stronger solutions may possibly endanger the kidneys. Hot baths and scrubbing of the skin to remove the dead epithelium should be resorted to, after the subsidence of the fever and throat complications. Many authorities urge the importance of warm baths daily from the appearance of the eruption. Oil of Eucalyptus may be used instead of the Carbolic Oil, and Corrosive Sublimate (1 in 4,000) has been highly recommended. Its occasional use would be unobjectionable. The writer has most faith in an anointing oil like the following:—

R. Olei Eucalypti ℥ivss
 Olei Amygdalar ℥xv.
 Olei Cinnamomi ℥iv, misc.

In the early stages a mild diaphoretic can do no harm, and for a child 2 or 3 years old a mixture may be ordered like the following:—

R. Spirit. Æther. Nit. ℥ii.
 Liquor Ammon. Acet. ℥iiss.
 Potassii Citratis ℥j.
 Syrupi Simplicis ℥i.
 Aquæ Camphoræ ad ℥iv. misce.

Fiat mistura. Capiat cochlearium minimum tertius horis.

When the fever runs very high small doses of Antipyrine may be given, and in adynamic cases, Quinine. When hyperpyrexia occurs, tepid baths and cold affusion may be tried, but these cases generally end fatally, and a cold pack is a less formidable expedient. The Salicylate of Soda often acts well as an antipyretic, but quinine is preferable. Carger states that there is no drug equal to Antifebrin, which he gives in 2 to 5 gr doses, and he uses it in conjunction with the wet pack. High temperature generally yields to cold sponging, and a favourite method is to apply cold compresses round the throat and ice to the head.

The drugs recommended for the routine treatment of scarlatina are very numerous, and statistics are quoted to prove the extraordinary value of most of them; it may, however, be affirmed that no drug has any specific action in this disease.

Bimiodide of Mercury, originally advocated by Dr. Illingworth, and maintained by many physicians to be a specific, has been extensively employed, but it has not fulfilled expectations. The writer's experience is too limited, but he has not any intention of trying it again as a routine remedy; 30 minims of the B.P. Liquor Hyd. Perchlor. may be given in a table-spoonful of sweetened water along with 2 grs. of the Iodide of Potassium every two or three hours. It is claimed that this treatment rapidly diminishes fever and prevents desquamation, and limits the period for isolation to between two and three weeks in all.

The Perchloride of Mercury has been used alone with similar glowing results, and Grey Powder has also been tried.

Salicylic Acid and the Soda Salt have been extensively used as routine remedies. Yeo puts faith in small doses of Phenacetin in combination with Quinine.

Mineral Acids, notably the Hydrochloric, are harmless agents, and appear to be as grateful and beneficial as they are in typhoid and typhus fevers, where their routine employment is generally spoken of as the Swedish method of treating fevers.

Oxygen and Peroxide of Hydrogen—the former as water charged with the gas, the latter as the solution prepared by acting upon Peroxide of Barium by Hydrochloric Acid—are safe remedies in adynamic cases.

Ammonia Carbonate in small doses frequently administered has been supposed to possess specific action, but there is little to be

said in support of the drug except in adynamic cases, and then only for a limited period is it admissible. It can be safely combined with Digitalis.

Curgeven extols the Oil of Eucalyptus. He gives internally a few drops in water, and sprinkles to saturation everything about the patient with it. Extraordinary success is claimed for the specific action of the remedy. The writer has long used it as an anointing oil alone or mixed with Carbolic Oil, and believes that it is a sure and efficient destroyer of the virus as it comes off by the skin, and much more reliable than weak Carbolic Oil, but internally he believes it to be valueless.

Chlorate of Potassium is a favourite drug for routine administration, especially in cases where the throat symptoms are very prominent, when it is often given in full doses, as well as being at the same time employed locally. It should be given with caution as it has caused or exaggerated nephritic complications, and at large doses it is dangerous. Upon the whole, its use should be limited to gargles and sprays in this disease where nephritis is a possible or likely sequela. The writer has seen it do serious mischief.

Benzoates of Soda and Ammonia have been recommended and used, but with somewhat doubtful success, and recently a decoction of Cinnamon has been found valuable in preventing the ear and kidney complications.

Sulphocarbolate of Soda has been much used in the treatment of scarlatina, and though the writer does not think it necessary to employ it as a routine method of treatment, nevertheless he resorts to it in cases of severity of fever or throat symptoms. A child 4 years old may get 2 or 3 grains every three hours. It is valuable in the later stages where suppuration of the throat has occurred.

Quinine in some severe cases appears to do well, and if combined with Iron it meets the requirements of reducing temperature and modifying the unhealthy action in the throat. Digitalis is used by some authorities as the best antipyretic in conjunction with Quinine, but it has no antipyretic action unless given in doses of at least 25 times the usual amount recommended by English writers.

The best routine local treatment for the majority of cases is a weak Carbolic solution sprayed into the throat. The following formula may be used with the youngest children.—

R. *Glycerini Boracis* ʒiv.
Glycerini Acidi Carbolici ʒiii.
Aqua Rosæ ad ʒxx. *misce.*

Older children may use this as a gargle, diluted with half as much water. The Glycerin of Carbolic Acid may be cautiously

applied on lint to the tonsils if any membranous exudation appears.

The method of applying a mild antiseptic to the throat and fauces continually through the disease has the sanction of the best authorities, on the grounds that the poison is given off in a concentrated form from the tonsils, and if swallowed tends to produce sequelæ. The practice of using the above carbolic spray, in the writer's opinion, certainly minimises the danger of ear complications and pharyngeal abscesses. (See under Throat, Sore.)

Gargles containing Chlorine, Bromine, Iodine, Corrosive Sublimatè, Iodide of Mercury, Sulphurous Acid, Permanganate of Potash, Sulphur, Tincture of Iron, Boroglyceride, Chlorate of Potash, and any other antiseptic may be used. These may also be employed as sprays. One of the most popular is Peroxide of Hydrogen Solution (1 in 4). Gager, in the Stockwell Hospital, syringes out the fauces and nares every 2 or 3 hours with a Chlorine Solution made by pouring 100 minims strong HCl on 3 drs. Pot. Chlor. and adding 20 oz. water.

Ice-d Compresses, Warm Poultices, Cotton Wool under oiled silk, or local Wet Packs, cold or hot according to the relief which they afford, may be tried; and where there is great swelling of the tonsils, steaming by holding the head over boiling water under a sheet or tent made in the bed may give ease.

Various opinions are held about the treatment of severe cases where the rash fails to come out. The hot pack must be used with great caution, especially if the temperature is high in such cases, but the administration of a hot bath containing a little mustard may be tried, for a few minutes only, with advantage. With a badly developed rash and a very high temperature the cold bath, cold affusion, or the cold pack may be cautiously employed, but cold sponging, if conscientiously carried out, meets all requirements.

Phloerapine, hypodermically, Aconite, Veratrum, and other drugs internally, seldom give good results under such circumstances, and their use is fraught with danger. Rheumatism, nephritis, adenitis, and other complications are treated upon the lines mentioned under their several headings. For the treatment of the otitis media, see page 249.

Six weeks is considered a fair average period of isolation, but complications and tardy desquamation may prolong it to nine. This period may be materially shortened by the use of soap, warm baths, and scrubbing, and there is little doubt but the free use of the Oil of Eucalyptus may in many cases safely reduce it to one month. Some authorities maintain when the anointing oil is used from the first in ordinary cases that the patient may get out of bed at the usual period (about 8 or 10 days), and freely move about and mix with others after a few hot baths andunctions. Such practice is certainly fraught with danger to the patient (if not to

others), as the greatest care is necessary to guard against chills all through the desquamating period.

SCIATICA.

Under the headings of Neuralgia and Neuritis (pages 591 to 611) all the various remedies found useful in sciatica have been fully discussed. They may be briefly summed up here for convenience. First, and by far the most successful in the majority of recent cases, is the author's method of using Morphine by the hypodermic syringe. This may be regarded as a combination of Acupuncture, Aquapuncture, Parenchymatous Injection and Narcotics (page 595); absolute rest, counter-irritation by blisters, liniments, actual or thermo-cautery; drugs, such as Salicylates, Salol, Quinine, large doses of Iodide of Potassium, Chloride of Ammonium, Phenacetin, Antipyrine, Exalgin, Cannabis Indica, Atropine, Arsenic, Iron, Phosphorus, Cod Liver Oil, Phosphide of Zinc, Cimicifuga, Gelsemium Ergot, Nitrate of Silver, Stramonium, Turpentine, Benzoate of Soda, the relative values of which are referred to under Neuralgia.

Local Anodynes, as Chloroform, Aconite and Belladonna Liniments, Veratrine, Menthol, Camom, Atropine, Methyl Chloride and Ether Sprays, are, as a rule, disappointing; so are injections of Antipyrine, Thime, Ether, &c. Electricity and Galvanism have been already discussed. They are sometimes of the greatest value alone or combined with hydropathy, Turkish baths, and massage. In chronic cases the great value of deep injections of a 1 per cent solution of Osmic Acid, combined with frequent punctures, has been already referred to.

Some cases yield to the local application of Sublimed Sulphur, cotton wool, and bandaging. Where these measures fail the operations of nerve-stretching, neurotomy, and neurectomy, as described upon page 607, may be resorted to.

It cannot be too plainly stated that the vast majority of cases of sciatica, as held by Gowers, are not cases of neuralgia, but of neuritis of the nerve. He, therefore, recommends absolute rest, counter-irritation, and the deep injection of morphia or cocaine; he much prefers the latter.

Weir Mitchell secures rest by a splint extending from the axilla to the ankle, to which the limb is bandaged. He uses cocaine $\frac{1}{2}$ to 1 gr. hypodermically, and in bad cases resorts to nerve-stretching. Dry-cupping he resorts to early in every case.

Recently Pille records success by the subarachnoid injection of 1 c.c. of a 2 per cent. sterilised aqueous solution of Cocaine.

SCLERODERMA.

The treatment of this condition is in the same highly unsatisfactory state as is its pathology. In the absence of any definite knowledge, the physician will be safe in paying attention to the general state of the patient, and in correcting any abnormal condition or violation of the laws of health.

Tonics, such as Arsenic, Phosphorus, Chloride of Gold, Nitrate and Oxide of Silver, and especially Cod Liver Oil and Iron, have occasionally been found of use when combined with warm flannel clothing and abundance of pure air and good food. Mercurials are harmful.

Massage, electricity, Turkish baths, and persistent inunction of the body by any animal oil or fat, if carried out with the internal administration of one or more of the above tonics, will give the best results to be expected in our present state of knowledge.

Recently Thyroid feeding has been lauded, but the reports of those who have had the opportunity of trying it are contradictory: nevertheless, in some cases marked benefit has been witnessed from it occasionally. The diseased condition is so rare that it will take a long time before a sufficient number of cases can be collected which have been submitted to the drug.

Sclerema neonatorum has been successfully treated by small doses of mild Mercurials; but the chief hope in such cases will lie in enveloping the body in successive layers of cotton wool, and keeping it in a very warm or hot room, and artificial feeding by a soft rubber catheter with peptonised foods and meat juice.

SCLEROSIS, Disseminated.

Little can be accomplished in the treatment of this disease. One drug after another has from time to time enjoyed some ephemeral reputation as a specific, but, nevertheless owing to the numerous complications which may arise during its progress, the physician may, by the aid of drugs and by the help of therapeutic measures, be able to prolong life and diminish pain and discomfort.

The avoidance of all depressing causes, as over-work, both physical and mental, worry, and extreme changes of temperature, is essential.

Iodide of Potassium appears in some cases to have the power of at least arresting the development of the disease, and it or the Iodide of Sodium should get the first trial in all cases coming under treatment; but the drug must be given for a long time, and in full doses, 10 to 15 grs. three times a day have appeared to the writer to check the progress of the degeneration for a time.

The next drug from which there is some prospect of benefit is the Chloride of Gold and Sodium, and Bartholow assumed that it sometimes cures. He stated that it had the power of causing absorption of connective tissues of pathological formation. The dose should be $\frac{1}{2}$ grain in pill twice or three times daily.

Nitrate of Silver appears to act in the same way, but its power of causing discoloration of the skin must be remembered.

Next in order of reputation comes Mercury, and some believe that the Perchloride in small doses, if given early, will arrest the disease. It should always be given if there be any reason to suspect the presence of a syphilitic taint, and it may be given

without any hesitation combined with the Iodide of Potassium omitting it each alternate month whilst the Iodide is continued.

Arsenic, Phosphorus, Zinc, and the host of so-called tonics have been recommended, and Cod Liver Oil should always be tried in early cases. Arsenic and Solanine have both been recommended hypodermically, but their value is doubtful.

Hydropathy, Massage, and Sulphur Baths have been found useful by Bastian in the early stages.

Galvanism and electricity are sometimes harmful, though occasionally they may appear to give temporary benefit.

Bed sores, bladder troubles, insomnia, and other complications are to be treated upon general principles, and no means by which the general nutrition of the body can be improved is to be neglected, and a point of considerable importance is to see that the patient is clothed in warm light woollen garments: a change to a warmer climate in winter is generally beneficial.

SCLEROTITIS.

As inflammation of the sclerotic is generally secondary to choroiditis or iritis, the details of treatment mentioned under these headings should be carried out.

In episcleritis, anodynes, as Atropine, instilled into the eye with a paste composed of Glycerin and Extract of Belladonna smeared over the brow, and a smart Saline purge followed by full doses of the Salicylate of Soda, will give relief in many cases.

Subconjunctival injections have come into very general use during the last few years in the treatment of episcleritis and scleritis. They generally consist of solutions of Cyanide of Mercury (1 in 5000) or Chloride of Sodium (1 in 200). The chief objection to their use is the pain which follows, but this may be largely prevented by adding to the fluid to be injected an equal part of a freshly-prepared 2 per cent. solution of Acain.

SCROFULA.

The view that this disease is but a tubercular affection, involving the lymphatic glandular system, is the one now generally accepted, though many details are still requiring elucidation. The practical therapeutics of this so-called diathesis is therefore that of tubercle and phthisis. Through the teaching of Alibert it has come to be recognised that scrofula is but a secondary event or 'hubo,' depending generally upon some peripheral cause, most commonly tubercle, which finds its way into the lymphatic system by a diseased tonsil or through the suppurating cavities of necrosing teeth, adenoids, &c. The abortive or preventive treatment is therefore obvious, the tonsils, fauces, and buccal cavity must be at once put into a healthy condition by the removal of all structures admitting the infective microbes.

The treatment of the enlarged glands is to be carried out on this principle, and the different methods by which they should be dealt

with will be found discussed under the heading Lymphadenitis, on pages 544-546. In those cases of acute suppuration where the infecting material may be some other pathogenic organism alone or in company with the tubercular microbe, the best plan will be simple incision and drainage.

About the face as small a wound as possible should be made, and it is a matter of great importance to ensure that the incision into the capsule of the gland is fully as large as, or larger than the skin opening. When very small a minute drainage tube or a few strands of carbolised tow may be inserted for a time, though this generally gives very slow results.

The greatest difficulty is experienced in the indolent glands which do not suppurate. Where constitutional measures, as improved dietary, fresh air, prolonged courses of Iodine, Iodide of Iron, Cod Liver Oil, Phosphates, Arsenic, &c., fail, local measures may be pushed, and the best of these is, as already detailed, a small incision and the thorough scraping out of the cavity when only one gland is involved. The application of iodine is now generally condemned. Where several glands are involved undoubtedly the best measure is their entire removal by the knife.

Treves states that iodine is probably in nearly all cases harmful, and he urges the necessity of securing absolute rest to the head and neck. He states that scraping and cautery puncture are only available for a very limited number of cases, and he insists that excision offers the simplest, safest, and most certain method of treating this obstinate affection, and expresses his opinion—"For no measure which has been employed for the treatment of the strumous neck can such excellent results be claimed as attend upon the simple excision of the glands. Considering the grave complications attending the disease, the tedious path it follows, and the disfigurement it leaves, it may be permitted to regard this operation as not the least of the improvements of modern surgery."

In the great majority of instances perfect recovery from the local lesion with very slight scarring, and a great improvement in the general health, may be confidently predicted.

SOURVY.

The remedies for this affection are free supplies of fresh vegetables both as preventive and curative agents. The disease has almost disappeared from observation since the almost universal introduction of steam in the place of sailing vessels, and the compulsory regulation insisting upon shipowners to supply Lemon Juice to their sailors. Fresh lemon juice is at once the best prophylactic, and the best remedy when the disease has become established. It may in this latter case be used freely in the presence of diarrhoea and dysentery. Indeed, as a general rule, it is useless to attempt the cure of any of the complications of scurvy as long as the blood condition remains unremedied. Therefore, as soon as the patient is put to bed, no matter what

his condition may be, *fresh* lemon juice diluted with water ~~should~~ be administered every hour or two. Lime juice, and even Citric Acid, where nothing better can be had, may be given. Fresh vegetables of every kind may be given—lettuces, salad tomatoes, cabbage, mashed potatoes, &c., and when these are available there is no necessity for lemon or lime juice, or drugs of any kind.

As soon as the condition of the gums permits, solid animal food may be used, and underdone roast meat or steak is the best. Strong soups, beef juices, and essences, or broths containing large quantities of fresh vegetable matters strained out just before administration, may be given when the state of the mouth prevents mastication.

Ulcers may be treated with a lotion of lemon juice. The bleeding gums may be improved by vegetable astringents used as mouth washes. The following is suitable :—

- R. *Tinct. Krameria* ℥j.
 Tinct. Calechu ℥ss.
 Decoct. Quercus ad ℥xxx. *misce.*

Where there is much fetor of the breath, weak Chlorine or Iodine Solutions or the Permanganate may be employed. Chlorate of Potash is a favourite local remedy. Alum is perhaps the best of all applications when mixed with some fresh Lemon Juice in water (1 in 40). Nitrate of Silver has been successfully applied to the sloughing gums.

Internally there is generally no necessity whatever for any drugs, but where hæmorrhages are extensive and threatening the old method of giving Ergot by the mouth or hypodermically has now given way to 15–20 gr. doses of Chloride of Calcium which rapidly increase the coagulability of the blood and stop hæmorrhage. The astringent preparations of Iron and the Tincture of Larch Bark may also be used. Gelatin Solution hypodermically or by the mouth is recommended, and Suprarenal Extract may be used.

Excessive salivation may be checked by Atropine.

Massage and Tonics, like Quinine, Iron and Arsenic are indicated during convalescence, and hydropathy hastens recovery.

The danger of a fatal syncope when the patient assumes the erect position in bad cases must never be forgotten.

Barlow has drawn attention to the frequency of scurvy in infants from condensed milk and peptonised and various proprietary foods. Such cases have been formerly regarded as *scorbutic* rickets, and occasionally both conditions occur together. Scurvy has not been recorded in bottle-fed children where fresh milk has been used. The practice of sterilising milk leads to the production of scurvy, as does also that of peptonising it constantly but the simple "scalding" of it, i.e., bringing it for a few seconds to

the boiling point, does not materially injure its antiscorbutic or antirachitic qualities. Meat juice, added to the milk prevents the disease. Treatment consists in giving *fresh* milk to which sifted potato is added. Beef juice or gravy, and a little sweetened orange, grape, or lemon juice, in water, should be given several times during the day.

SEA-SICKNESS.

The usual advice of recommending a hearty meal before going on board is a mistake, and fasting is also to be avoided. A light meal at least three hours before experiencing the ship's motion, and a *large warm water enema*, will put the patient in the best condition for struggling against this distressing malady. Of prophylactics there are hosts recommended, but few are of the least use to patients susceptible to sea-sickness. The safest remedy, and one which undoubtedly often succeeds in preventing the attack, is the Bromide of Sodium, which should be given in 20 grain doses for a day or two before embarking. Hyosciamine Hydrobromide, in perules $\frac{1}{16}$ gr. each, appears upon the whole to be the best drug, and the patient should take one a few hours before going on board. Very susceptible travellers may be put under their influence for 2 or 3 days before starting on the voyage. McDougall injects hypodermically $\frac{1}{16}$ gr. Sulphate of Atropine and 4 times this amount of Strychnine at the very onset of the nausea or discomfort, and the results obtainable are very satisfactory. As soon as a susceptible patient gets aboard, he should lie down flat upon his back with his head low and his eyes closed. A light abdominal binder, or pressure applied to the epigastrium is useful in many cases. The general advice given to keep walking about upon deck is very good to travellers not markedly susceptible, and many such undoubtedly escape sickness in this way, but the very sensitive are sure to succumb if they adhere to it. One dose of Chloral (20 grs.) with the Bromide may be tried when the voyage begins at night, and the Bromide may be combined with Antipyrine.

Ice to the spine has been recommended, but its inconvenience is a barrier to its extensive trial, in conjunction with it the feet and hands should be plunged into very hot water.

Morphia, Opium, Cannabis Indica, Cocaine, Chloroform, Caffeine, Atropine, Alcohol, and Nitrite of Amyl have been recommended as prophylactics but the writer has rarely found any benefit from them, though they all will give some relief after the vomiting or nausea has set in. Nitroglycerin is often very valuable, but its use is unfortunately attended with such drawbacks as prevent its being put into the hands of ordinary travellers. It sometimes does prevent sea-sickness, and the writer has observed a curious fact in connection with its action—viz., that if it fail to prevent vomiting, it often effectually removes the depression and apprehension

accompanying the attack, some patients under its use feeling almost no nausea though vomiting may be frequent, and a few apparently are almost able to enjoy the retching. Its danger is in the possibility of the tablets (the only convenient form of administration) lying for a time undissolved in the stomach and then getting into the circulation all at once. One of the P.T. Tablets may be given every hour for four doses.

Nitrite of Amyl may be used instead of Nitroglycerin, but its action is too fleeting. Antipyrine and Antifebrin generally for their best effects are obtained when given frequently in small doses (2 grs.), with Cocaine ($\frac{1}{4}$ grain). Chartier recommends under the name of Chlorobrom 30 grs. each of chloralhydrate and bromide of potassium. For the relief of the vomiting, when once established any of the anodynes already mentioned as prophylactics may be tried. Ice sucked in the mouth, or Ice Champagne, or an effervescent Alkaline Mixture is indicated. Stimulants or anodyne liniments may be applied to the epigastrium. Hydrocyanic Acid, Bismuth, Creosote, and the usual gastric sedatives may have a trial, and lozenges of Eucalyptus Rostrata are said to be very efficacious. Food should be insisted upon after a time, owing to the dangerous exhaustion setting in upon long voyages, and the appetite may be assisted after vomiting has ceased by the administration of a little combined with a Mineral Acid, as 15 minims of the Diluted Hydrochloric Acid in a table-spoonful of Infusion of Gentian three or four times a day.

SEBACEOUS CYSTS.

When the cyst occurs upon the scalp the hair over it should be cut close, and the skin cleansed by washing with a weak sublimed solution. An incision made with a fine scalpel suffices to permit of the shelling out of the cyst with its wall intact, the dissection being accomplished by a few strokes of the point or by the handle of the scalpel or blunt end of the forceps. Where these tumours are situated upon the face or forehead a very small incision in the skin and cyst wall may be made, and by firm pressure of the thumb the sebaceous matter can be squeezed through the opening, after which the wall of the cyst should be forcibly dragged through the incision. It is more satisfactory to dissect out such cysts without rupture or extravasation of their contents, and in portion of their walls should be left behind. The lines of the incision should take the direction of any natural lines, furrows, or wrinkles, so as to avoid unnecessary marking.

The after-treatment of the wound is to be conducted upon general surgical principles, but by far the best way is that which the writer always employs, viz. — After seeing that the hæmorrhage has ceased and the wound rendered thoroughly aseptic, by the free use of Carbolic Lotion, the lips are brought together, and by gentle pressure for a few minutes, every trace of moisture is dried up by absorbent wool, when a few layers of Collodion appear

over the wound and neighbouring skin fixes the edges of the wound together, and by its pressure as it dries up it prevents further oozing, and almost always ensures healing by first intention.

The plan of causing suppuration by the application of caustics or the injection of irritants into the cyst has nothing to recommend itself. The injection of Ether with the view of causing solution of the sebaceous matter and its subsequent absorption does not succeed.

Where the cyst has already suppurated, it should be treated as an ordinary abscess by a free incision, and its contents may then be washed out by an antiseptic solution. After the subsidence of all inflammatory action the cyst wall may be excised if it has not already sloughed out.

SEBORRHOEA—See Dandruff (Page 190).

SEPTICÆMIA.

The principles of the treatment of septicæmia, or so-called blood poisoning, will be found mentioned under Puerperal Fever.

In a general sense, it may be said that the first thing to be done is to find out and treat the cause. As this is generally the result of some wound or injury through which the septic material has gained access into the system, it will be found necessary to open it up and use free irrigation by antiseptic solutions and establish thorough drainage. In the case of poisoned wounds it will be necessary to destroy any poison at the seat of its admission by strong caustics, after which the freest outlet is to be established and ample drainage provided for, and all tension effectually removed. Poulticing as ordinarily carried out is to be avoided, antiseptics being preferable. Constitutional treatment as detailed under Pyæmia, especially pure air, abundant ventilation, milk diet, and strong soups at a later stage, with Quinine, Iron, Strychnine, and the general remedies described under Pyæmia and Puerperal fever, will be indicated.

SHINGLES—See Herpes (Page 415).

SHOCK—See Collapse (Page 156).

SLEEPLESSNESS—See Insomnia (Pages 459 to 472).

SMALL-POX—See Variola.

SNAKE BITES.

Hitherto the only available treatment for the bites of venomous serpents was that which general surgical knowledge suggested. A ligature should be immediately applied above the bite, this is useless unless thoroughly done. The ligature should be drawn very tight by inserting a small stick under the cord and twisting it, after this the wound should be irrigated. About the only

available method of accomplishing this without delay is to suck the wounded part by applying the lips, and then to wash the mouth with spirits or any antiseptic. If there be no abrasion, it may be regarded as practically harmless. The wound, however, should be excised without a moment's delay. The ligature should be kept on for at least half-an-hour. In the case of the cobra, the highly poisonous serpents these measures nearly always fail, so terribly active is the venom and so rapid is its absorption. The writer was informed by a friend long resident in the East that he could obtain no evidence of recovery from cobra bite (outside the circle of snake-charmers) save in one solitary instance, and that was in the case of a man who, whilst chopping wood, was struck in the finger by the snake. Recognising his danger, he amputated the finger by instantly bringing down his uplifted axe. The writer mentions a plan resorted to by hunters in India, who punch the bitten part and cut it out, thrusting gunpowder into the wound and igniting it, with the view of cauterising effectually the lesion. The hypodermic injection of Potassium Permanganate has been successfully used in rattle-snake bites, and Carbolic Acid has been successfully tried in venomous bites of different kinds. Hypochlorite of Lime (2 per cent.) and Chloride of Gold (1 per cent.) by Calmette have been successfully injected into the region of the bite, but these measures should not be relied on, except when practicable, amputation of the part should be performed. The intravenous injection of Ammonia and the hypodermic administration of Strychnine have been credited with the saving of life, but opinions are much divided upon their utility. They both appear to give some relief to the urgency of the symptoms. Alcohol in large amount must be administered as soon as symptoms of poisoning show themselves, and other cardiac stimulants may be given freely to combat the serious collapse which often rapidly supervenes.

The researches of Calmette and Fraser upon this subject must be regarded as amongst the most brilliant in the new domain of serumtherapy. Fraser, by administering small doses of snake poison to animals, found that they rapidly came to bear lethal, and finally enormous doses without hurt. Serum extracted from these immune animals produced protection in other animals, and this is of vital importance to the therapeutics of our Indian Empire (where 22,000 deaths from snake bites annually occur), he found that the serum, if injected soon after the hypodermic lethality of the poison, saved the animal. He concludes, after many experiments, that "it has been established on the clearest evidence that the blood serum (antivenene) of animals, protected against large lethal doses of venom, is able in varying conditions of administration perfectly to prevent lethal doses of the venom of the most poisonous of serpents from producing death in non-protected animals."

There are obviously enormous difficulties in the way of prepar-

ing the antidotal serum or antivenom. Calmette's antivenom is administered in doses of 10 c c., and already several cases of cobra and other bites have been successfully treated by it, and the remedy doubtless will come to be of the greatest value as a life-saving agent.

Calmette, however urges the importance of thorough ligaturing of the limb and irrigating the wound freely with a fresh solution of good Bleaching Powder (1 in 60) in addition to the injection. An able and most comprehensive article on this interesting subject will be found in the Sept. 9, 1899, *B. M. J.*, by D. W. Andrews, R.N.

SPERMATORRHOEA.

The term is an unfortunate one ; very generally relief is sought from seminal emissions which occur in unmarried subjects who are chaste ; these cases often are associated with serious mental worry chiefly caused by the perusal of quack literature. A candid statement by the physician generally sets the mental suffering right, and advice to avoid all impure literature and conversation and to partake of active physical exercise, will produce beneficial results. A full dose of Broude (30-40 grs.) at bed-time should be tried.

In those cases where the condition is the result of prolonged self-abuse or sexual excesses the same lines may be carried out.

Under the heading of Masturbation the treatment of the common factor operating in the production of spermatorrhoea in the great majority of cases has been already detailed, and under Hypochondriasis, page 435, the treatment of the mental state so frequently associated with it is described. If any local condition is discovered it should be remedied without delay, as elongated prepuce, fissure of the rectum, hæmorrhoids, balanitis, phimosis, &c., the treatment for which affections will be found in their proper places in the present volume. If the exciting cause of the discharge (which occurs without any sexual excitement) is remedied, the mental and physical condition may be expected to improve. The discharged fluid is often purely prostatic.

Lallemand's treatment still finds acceptance with many surgeons. It consists in cauterising the prostatic portion of the urethra by means of a solution of Nitrate of Silver (30 grs. to 1 oz.) and a urethral syringe, or by applying the solid Caustic with an instrument devised for the purpose. Free blistering over the lumbar centre in the cord followed by the regular application of a counter-irritant like D'Albepseyre's paper to keep the surface raw for 4 or 6 weeks is often beneficial.

Phosphorus, Arsenic, Chloride of Gold, Electricity, Massage, and the general treatment recommended under the head of Impotence page 447, may be resorted to in suitable cases, but more frequently the remedial and moral agents detailed under

Hypochondriasis, on page 435, will be indicated. Success is claimed from the injection of testicular juice or of spermin.

SPINA BIFIDA.

Of all the methods of treatment the one still most frequently carried out is a modified form of Velpeau's operation. The infant's health and strength have been brought up to the state requisite for an operation by judicious feeding and skilful nursing; the operation should not be undertaken, the tumour being meantime protected by a layer of collodion, cotton wool and shield of gutta-percha modelled to suit the part. The tumour should be punctured through the healthy skin near to its base by a fine platinum needle, and if tense a small amount of its fluid contents removed after which about one drachm of Morson's solution is to be injected. Large tumours may receive double the amount; half a drachm will be sufficient for small ones —

R. *Iodi Purificati* gr. x.
Potassii Iodidi gr. xxx.
Glycerini ℥i. *misce.*

It will be advisable to place the child upon its face during the operation and to carefully close the punctured opening by collodion over which is placed a pad of cotton wool and a flannel bandage. One injection sometimes suffices, but it often may require several, the greatest care being taken to prevent injury to or rupture of the sac and loss or draining away of the cerebro-spinal fluid.

The operations of simply painting with collodion, tapping followed by compression, introducing setons, ligaturing the tumour or excising a portion of the sac, are very seldom successful, and except the first-mentioned, they are generally very dangerous.

Bayer recommends the treatment of the tumour as if it were a hernia. He dissects out two lateral flaps from the skin covering it and removes the sac leaving only two lateral flaps of the skin which he sews together after rendering the wounds aseptic, the skin and muscles being afterwards brought together separately. He also suggests that two lateral periosteal flaps may be dissected from the canal of the sacrum in order to make a bony roof for the sewed sac. Removal by the knife under strict asepsis is every year gaining in favour. The prospects of success depend chiefly on the presence or absence of nerve fibres in the sac and on the size of the opening in the bony canal. Several cases have been recorded in which successful removal has been followed by hydrocephalus.

SPINAL CURVATURE.

Under Caries, page 130, the treatment of antero-posterior curvature, or Pott's disease, is detailed.

Lateral spinal curvature, it seen to before enormous protrusion

Deformity has become established, yields rapidly to treatment. When confirmed structural curves exist, treatment with the view of removing the deformity is practically useless.

In the early stages of the affection, all that is required is attention to the general health, suitable gymnastic exercise, and the avoidance of those habits and postures which have led to the development of the affection. *The use of spinal supports, and prolonged rest in the recumbent position on a couch or in bed, are positively injurious in the great majority of cases, and Sayer's jacket is worse than useless.*

Roth places the patient in a perfectly normal position (this is very easy in most cases where osseous permanent deformity has not set in, and he insists upon his maintaining this posture before a mirror, lying, standing, or sitting at regular intervals till his perverted muscular sense is restored. As soon as this occurs, the patient begins to realise that the easiest position has hitherto been the abnormal one. By close attention afterwards to the strict maintenance of the improved position in standing, sitting, or walking, a rapid cure results. In his able article in Heath's "Dictionary of Surgery," a list of elaborate exercises are minutely given, to which the reader is referred. Games of all kinds, including rowing and lawn-tennis, with the ordinary gymnastic exercises, may be freely indulged in in all cases of lateral curvature, short of causing severe fatigue or after-pain. The writer, contrary to the advice of some surgeons, always recommends swinging upon the horizontal bar, and finds that the improvement in the rapid development of the muscles of the back often effects a very speedy change.

Where there is marked paralysis of the erectors spine muscles, so that the patient is unable to assume an improved position, the use of a spinal support taking its fixed point from the pelvis, and lifting the weight of the head and upper extremities off the spine by means of two crutches made to fit into the armpits, affords considerable relief. As long as there is any hope of development of the weakened muscles in spinal curvature, however, these appliances do harm. A light poroplastic jacket often is better borne than the steel supports.

They may occasionally serve in arresting the formation of permanent curves in rapid cases, but then only by being regularly used in conjunction with gymnastic exercises.

Even in the most advanced cases of osseous deformity, their constant use often does harm, and the persistent employment of injudicious gymnastic exercises in these cases may afford great relief to the wearying pain felt in the back and chest.

Massage and electricity applied to the muscles of the back may do much when tried in conjunction with the above methods.

SPINAL INJURIES.

Absolute rest in the prone position on a very hard hair mattress or firm couch is the first clear indication in the majority of cases, and

in simple concussion it is all that is generally required. Symptoms of hæmorrhage, myelitis, and paralysis are to be met by the ~~age~~ already mentioned under these headings. Much has recently been written about the advisability of surgical interference ~~where~~ there are evidences that direct injury to the bones or cartilage has occurred. In simple fracture brilliant results have been obtained in some cases, and some surgeons advise trephining in every case of spinal injury followed by symptoms of compression of the cord. Horsley, after discussing the question of early operation, summarises as follows — (1) If the lesion is acute and in the cervical region, then certainly wait. (2) As regards the dorsal region, it is better to wait a little. (3) In the lumbar region, do not think you require to wait. In old standing cases, with persistent symptoms, all surgeons are agreed that operation is desirable unless the cord has been completely divided or myelitis has set in. Thorburn has pointed out the advisability of operating in all cases of injury to the cauda equina.

Some cases of fracture have been successfully treated by Sargol Jacket. The prevention of bed sores constitutes a considerable part of the treatment in all cases, and a water-bed is essential.

OPERATION

If seen immediately, or very soon after, before swelling has occurred, the writer has found the following simple plan act most satisfactorily in some cases. — A rubber bandage is applied with moderate pressure, and the bandaged joint is placed under a cold water tap for as long as the patient can bear it. By this method, sometimes the duration of the treatment may be limited from an hour or week to hours. If the pressure begins to give severe pain, the bandage must be taken off, and cold water applications continued or ice-bags, or an irrigation apparatus, or ordinary cold evaporating lotions containing Chloride of Ammonium, Lead, or Spirit.

The plan of immediately enveloping the sprained joint in a thin plaster or starch bandage is highly recommended by many authorities, but the feeling that one cannot see what is going on under these when pain afterwards becomes severe, as it does in some cases, renders the mind of the patient or of his attendants uneasy, and the removal of such a bandage over a swollen limb is no easy matter. A properly-applied bandage should prevent swelling, but sometimes it does not, and then it is exceedingly painful.

Warm applications are the most comfortable where severe pain and swelling have already occurred before the surgeon has seen the case. Warm or hot fomentations, or a good poultice are sometimes very soothing. Putting the limb into as hot water as the patient can bear may be tried. Upon the whole, however, the best all-round method is to envelop the joint with strips of lint soaked in the following lotion or in Spirit Lotion (1 in 4), and then

Carefully cover over with oiled silk or thin mackintosh, kept in place by a light bandage :—

R. *Liquor. Plumbi Fort.* ʒj.
 Tinctura Opii ʒii.
 Acid. Acetic. Dil. ʒii.
 Aque ad ʒxxx. *misce.*

This may be applied warm. It also serves well if used as a cold evaporating lotion.

Leeches applied to a very swollen and painful superficial joint often give more relief than anything else.

Absolute rest is to be rigidly maintained till after the subsidence of the acute symptoms, and the starch or plaster bandages secure is most effectively when they can be tolerated. Any form of bandage may be adjusted to the limb. Often, in ordinary practice, the physician generally finds that the rest is liable to be maintained for too long a period, and the method of keeping a plaster or starch bandage for six or eight weeks upon a sprained joint is to be condemned. Passive movements, friction, and massage may be commenced as soon as the disappearance of the pain and swelling. The too early use of the limb may lead to a slow convalescence, and the great majority of cases of stiffness and impaired use of joints after sprains are caused by an unnecessarily prolonged rest, which sets up changes in and around the joint.

Mild sprains may be successfully treated by massage from the first. The patient should not be permitted to use the joint himself, nor to place the weight of his body upon it till passive movement, massage &c. can be tolerated without pain. In even the worst cases these agents may be commenced before the end of the third week. Strapping consisting of Soap or Lead Plaster spread upon any strong material, may be applied neatly round the joint in bandages before the patient is allowed to move about.

Recently, severe sprains of the ankle joint have been successfully treated by immediately strapping firmly with plaster the foot, ankle, and lower third of the leg, and permitting the patient to walk about at once as if nothing had happened.

QUINTING.

The first consideration is to find out the cause and treat it, and if possible secure its removal.

Ordinary convergent strabismus in young people is almost always the result of hypermetropia or hypermetropic astigmatism, and in some cases it may be cured, for a time at least, by keeping the eyes under the influence of weak Atropine Solution, and so relaxing the ciliary muscle and preventing attempts at accommodation and its accompanying convergence. In all cases, however, the vision should be carefully examined, and correcting

glasses ordered. In young children these glasses should correct the total hypermetropia, and should be worn constantly, while a drop of Atropine (1 gr. to the ounce) should be instilled every morning into both eyes. In a large number of cases, and especially in those of recent origin, this effects a complete cure. This treatment should be persisted in for several months, and then when the atropine is stopped, weaker glasses will be necessary. The squinting eye should be exercised for half an hour daily by covering the good eye.

Where these measures fail, tenotomy of the internal rectus of one or both eyes must be resorted to. This should not, as a rule, be done sooner than the eighth year. It may be necessary to operate sooner if there are signs of the vision becoming affected though by closing the good eye several times daily and exercising the weak one this generally may be prevented and operation put off till the age specified.

As it is often impossible to predict the exact amount of correction resulting from the operation, a second operation may be required but it is wiser not to divide both recti at one time. The full effect of the operation is often not seen for several months, and if too much is done divergent strabismus may result. If vision is very poor in the squinting eye, an operation is not likely to do permanent good though for a few months it may seem to be improved. In such cases it is better to try to improve vision by exercising the squinting eye before operation.

After thoroughly rendering the conjunctiva insensible by Cocaine the tendon may be easily divided without giving any pain. The first step after the introduction of the speculum is to seize a portion of the conjunctiva by forceps, and with the scissors produce an opening through which the hook and the blades of a pair of fine scissors may be passed, and as the tendon is caught by the hook it is divided by the scissors close to the sclerotic.

Convergent strabismus, the result of myopia, is generally remedied by suitable glasses, but where these fail, tenotomy should be performed.

Paralytic convergent strabismus must be treated by remedying the underlying mischief, which may be syphilitic, being often caused by the presence of gummatous tumours behind the orbit, or by syphilitic affection of the orbital bones. Whilst Mercuric Iodide of Potassium is being employed it will generally be found necessary to remedy the double vision caused by the strabismus by means of closing up one eye, and at several times during the day the affected eye should be exercised, so as to prevent wasting of the paralysed muscles. For the same reasons massage and electricity may be used, and in very bad cases tenotomy will be required.

Divergent squint is a more troublesome affection to remedy. The very mild forms may be sometimes removed by suitable concave glasses to correct the myopia which is often the cause.

The external rectus will require tenotomy, whilst the internal must be shortened or advanced. Success will to a large extent depend upon the state of the vision of the affected eyes.

Javal has recently reported a case where tenotomy had been performed on both eyes with unsatisfactory results, but success followed the use of the stereoscope after the patient had for a considerable time worked twelve or fourteen hours daily trying to reduce single vision.

It should be remembered that after tenotomy for strabismus the painting eye must be constantly and steadily exercised, otherwise the sharpness of vision will not be improved.

TALKING.

After remedying any local abnormalities or diseased conditions of the mouth, throat, or air-passages, the treatment must be purely educational. The greatest slowness and deliberation must be maintained during the necessary vocal exercises, the first of which must be the difficult one of teaching the stammerer to keep his chest always well filled with air. Nothing, however, will be gained without the exercise of much patience.

The patient should read aloud slowly with a good teacher, practising over and over again the combinations of sounds which are the greatest difficulty, with patience and deliberation. In very bad cases a beginning may be made by singing or rhyming, after which, by repeated exercises in loud, slow reading, improvement will gradually show itself.

Rules are useless for such exercises. The assistance of an experienced teacher is of all things the most important, and the patient should be educated as far as possible to refrain from speaking when under the influence of nervousness, excitement, or passion.

Corval has reported astonishing results from Hypnotism, the effects being speedy, and in some cases complete cure results.

Various drugs, as Bromides, Hyoscyamus, Stramonium, &c., and most antispasmodics have been tried, but they are useless as a rule.

STARVATION.

The obvious remedy for this condition is food, but the most cautious and discreet exhibition of aliment is essential. Death rapidly supervenes in many cases where the sufferer is permitted to suddenly satisfy the cravings of hunger following a forced abstinence from food. The most easily digestible substances should be sparingly administered at very short intervals, and milk, beef tea, or meat juices afford the safest means of supplying these. Solids must be sparingly administered for some time, or entirely withheld till the digestive organs recover sufficient tone. White rice, boiled, is the best form in which to commence the exhibition of solids. Children and infants, upon being rescued from a state

of acute or chronic starvation, do best upon diluted whey peptonised milk.

A matter of vital importance, which may be readily overlooked in these cases, is the state of the body temperature. In starvation this falls so low as to cause death, and life may be saved in some cases by a prompt application of dry heat to the body of the victim rescued from starvation. In some cases heat is more urgently demanded than food. It is advisable to apply hot water bottles and warm flannels and cotton wool rather than at first to attempt friction or massage, which might possibly, under such circumstances, extinguish life. Upon theoretical grounds the ^{Wheat} would suggest that the hypodermic injection of Saline Solutions might be useful.

In the voluntary starvation of lunatics, the gag and the rubber tube of a stomach-pump may be employed to convey liquid food into the stomach, or, where there is difficulty in introducing the tube through the mouth, it may be sometimes passed along the floor of the nares.

STERILITY.

The treatment of sterility in the male will resolve itself into the remedying of the causes as far as these are capable of remedy. Where impotence is absent, and the sexual act is performed in its normal manner but where there is absence of spermatozoa from the seminal fluid, little need be expected from any methods of treatment unless in those rare cases where the azoospermation is caused by some temporary obstruction of the efferent ducts of the testicles, as from recent epididymitis, when appropriate remedies may be of use. Should this condition depend upon exhaustion from recent venereal excesses, without impotence, abstinence will generally correct it in a short time; but where prolonged abuse of the sexual instinct has led to marked atrophy of the testicles, no medication will be of the least use in cases where spermatozoa are absent from the seminal discharge, or in cases where both testicles are retained in the canal or abdomen.

In sterility caused by absence of the seminal emission at the time of sexual intercourse, if this depends upon any mechanical impediment, as phimosis, hypospadias, diseases or concretions in the prostate, stricture of the urethra, &c., it may be remedied effectually by removal of these causes.

Where, from nervous or psychical causes, the discharge of seminal fluid is delayed or absent, though the sexual act may be otherwise successfully performed, treatment generally is of little avail, though in such comparatively rare cases the remedies mentioned under Impotence (page 437), as Phosphorus, Strychnine, Electricity, &c., may have a trial. Curling and McCarthy recommend the application of blisters and irritants to the glans and penis in those cases characterised by deficient sensibility of this portion of the genital apparatus.

Sterility in the female often depends upon remediable causes, and it must be borne in mind that not unusually more than one cause may be present at the same time, and the mistake should not be made of stopping short of correcting abnormal conditions of the various parts of the genital tract. Details of treatment here are unnecessary, as they are supplied under the different headings of the abnormal or diseased conditions interfering with conception, as Uterine Displacements, Metritis, Leucorrhœa, Ovarian Disease, Gonorrhœa, Vaginismus, Dysmenorrhœa, Tumours, Salpingitis, Endometritis, Syphilis, Obesity, &c., &c.

STINGS.

In the case of wasp and bee stings the immediate application of Liquor Ammoniac gives almost instantaneous relief. Sal Volatile answers the same purpose, but acts less rapidly. Where the sting is left in, it should be extracted by forceps, and in the coarse skin of the palms of the hands or soles of the feet the strong liquor may be applied. Alkaline Carbonates may be employed in the absence of Ammonia. Thus a strong solution of Carbonate or Bicarbonate of Soda or Potash may be tried. Chloroform or strong Oil of Peppermint gives relief, and a little pure Carbolic Acid may be applied on the end of a match to the puncture, or Carbolic Oil (1 in 8) may be more freely applied. In the absence of Ammonia an excellent remedy is Indigo used in the form of the domestic "Blue Bag."

If erythema and swelling have already appeared, Ammonia may increase the irritation. In such cases a poultice with some Alkaline solution, as Lime Water, sprinkled over its surface, acts well.

Peppermint Oil relieves the pain and irritation of mosquito bites, and Pennyroyal Oil (*Hedeoma Pulegioides*) is much used both as a remedy and preventive. Camphor, Oil of Cloves, Oil of Cinnamon, and Oils of Rosemary, Eucalyptus, or Cajuput act in the same way as preventives. Poultices of Ipecacuanha and Mint Leaves relieve mosquito bites. Scorpion stings are also successfully treated by Ammonia and Chloroform, Alum, and Carbolic Acid.

Where sudden collapse follows the stings of bees, wasps, or scorpions, Ammonia and Brandy or Whiskey internally may be urgently required. Spider bites are best treated by Carbolic Acid, and sometimes a small incision to permit the entrance of the Acid into the immediate region of infection. A ligature round the limb if applied at once in the absence of remedies, will give time for the destruction of the poison by sucking, washing, or cauterising the spot in cases where a severe or dangerous result might be anticipated. Mueller's method by injecting Strychnine hypodermically in tarantula and venomous bites gives good results, $\frac{1}{2}$ gr. may be injected every hour for 3 times. (See also Snake Bites, pages 877.)

STOMACH, Dilatation of.

The first step after diagnosis has been made, and with the view of verifying it, is to wash out the stomach. Lavage has been referred to under Gastric Ulcer. In dilatation, whether of the atonic form or in cases depending upon pyloric obstruction, the stomach should be washed out daily by the rubber tube with its attached funnel, which is now to be had at every instrument maker's. After syphoning off the contents of the stomach, water is poured in and syphoned off till the washings become clear, many pints or quarts being used. The amount of water poured into the stomach at any one time should not be over a few pints, though the writer upon one occasion poured in two gallons before syphoning off this amount, this he would consider now as wholly unjustifiable. This was several years ago, and the patient survives and washes out his own stomach daily with great relief to himself. A little Permanganate of Potash or Creosote may with advantage be added to the water, but it is doubtful if boric acid should be used; the best temperature is that of about 90° F. After the organ has been got into fair working order the lavage may only be necessary every second or third day, the patient should be seated in a chair, but the operation can be carried out upon a couch. In pyloric stenosis great relief will be always obtained, but the remedy is useless in most instances as a curative agent, the surgical procedures mentioned under Cancer and Gastric Ulcer being necessary. Lavage in atonic dilatation, combined with the next aid in the treatment, often is curative.

Diet must be as carefully arranged as in the case of ulcer but with this radical difference, that the food should be administered in as dry concentrated a form as possible or convenient. Where there is much fermentation starchy foods and cooked fats must be avoided, and, as a rule, milk, owing to its bulk, is not to be given as in ulcer, unless where there is only a very partial stenosis. Strong soups and beef jellies, and often lean mutton chops, with toasted bread, answer better than anything else. Fluids at first may be given by the rectum. Benger's Food and peptonic dishes are essential where the gastric juice is deficient, and, as a rule, in all cases feeding every four hours is advisable.

The writer has found in two cases surprising benefit from directing the patient to so alter his posture as to permit the gastric contents to come more directly into contact with the narrowed pyloric orifice, the experiment should always be tried, and the patient soon discovers for himself the best position.

Massage and Electricity are always of some use, especially in atonic cases, and the drugs to be most depended upon are Pepsin with Soda and Magnesia (see page 244) and Creosote in capsular form. The writer has seen most remarkable cures from gastro-enterostomy.

STOMACH, Diseases of—See under *Dyspepsia, Gastralgia, Gastritis, Gastric Ulcer, Cancer, &c.*

STOMATITIS.

The treatment of the gangrenous variety of stomatitis is described under *Cancrum Oris*, page 1261. For the catarrhal, ulcerative, and follicular varieties the treatment is simple, and may be carried out upon much the same lines as that of Aphthous Stomatitis (page 571).

Diet should be as nutritious as possible, and for children peptonised milk foods or peptonised beef tea and chicken soups are required. In all cases of severity a liquid food is necessary, and upon investigation something will generally be found to have been wrong with the feeding and general management of the patient prior to the attack. This should be corrected at once. Food should be properly cooked and given at proper intervals. Pure fresh air and sunlight are necessary, and everything that can place the patient in the most favourable hygienic condition should be resorted to. Local treatment is of importance, and all cases generally soon yield to the continuous use of the Glycerin of Borax, applied by a brush or by the finger every hour or two.

For the condition occurring in young infants, and commonly known as "thrush," which is closely allied to stomatitis, the same treatment is successful. It is generally produced by the presence of *saccharomyces albicans*, and yields to the Glycerin of Borax. Where there is evidence that the affection has extended to the gullet, and is associated with gastric and intestinal disturbance, Salol in small doses is indicated. Baginsky recommends $\frac{1}{2}$ to $\frac{1}{4}$ gr Resorcin in solution every two hours. The sterilisation of feeding bottles, teats, and all utensils used by the infant is essential, as the disease may be readily communicated to other infants in lying-in and children's hospitals.

In the cases of minor severity coming on during the course of other diseases in adults, the writer's plan is to give one large crystal of Borax to the patient, with directions that he is to lick it frequently through the day.

Chlorate of Potash, in the form of tablets, is an excellent remedy. One may be kept in the mouth and allowed to dissolve very slowly. Like Borax if its use be continued after the disappearance of the stomatitis, it may set up an irritation of its own, which, however, ceases as soon as its use is suspended. It is frequently used in solution ($\frac{1}{2}$ oz. to 1 pint). Boric Acid (1 in 30), Carbolic Acid (1 in 100), Glycerin of Alum, Salicylate of Soda (1 in 20), or Lime Water may be used.

The occasional use of a weak solution of Corrosive Sublimate, 1 grain in 6 oz. distilled water, is advisable in the stomatitis of adults.

Where ulceration is extensive the sores may be touched with solid Nitrate of Silver, or brushed over with a strong solution. The Sulphate of Copper, Burned Alum, and Strong Hydrochloric Acid are used for this purpose. A weak solution of Permanganate of Potassium may be frequently used where there is much fetor.

Where bleeding from the ulcerated spots occurs vegetable

astringents, as Decoction of Oak Bark, Rhatany, Myrrh, &c. may be useful.

Where the state of the mouth is such as to render feeding very painful, Cocaine may be employed, or even forced feeding with a rubber tube, or rectal alimentation may be resorted to.

Of internal remedies none equals a combination of Iron and Chlorate of Potash, which may be safely given at all ages.—

R. *Potassii Chloratis* ℥ss.
 Tinct. Ferri Perchlor. ℥ss.
 Glycerini ℥i.
 Aquæ Destillatæ ad ℥xii. *misce.*

Fiat mistura. Capiat cochleare magnum quater in die et paululo aquir.

Infants may take a small tea-spoonful of the above.

Tincture of Cinchona may be added where there is much depression, and Cod Liver Oil is always useful.

Mercurial stomatitis is best treated by constant washing out of the mouth by means of Chlorate of Potash washes (1 in 30) in the intervals the tablets of the same substance may be employed, and where there is much fetor Chlorine Solution or Potassium Permanganate may be freely used. At a later stage the vegetable astringents are indicated. Internally Chlorate of Potash is the best remedy and it is hardly necessary to state that mercurials are to be suspended. (See Ptyalism.)

For the not uncommon condition known as "spongy gum," and for the condition where pus wells up between the gum and the tooth (Pyorrhœa Alveolaris or Rigg's Disease), generally depending upon an abnormal condition of the secretions of the mouth, or upon the presence of tartar, attention to the general health, especially to the gastric or digestive functions, and the removal of tartar, are essential. Astringents like Chloride of Zinc, Copper Sulphate, or Chlorate of Potash may be used, and the following local application is of the greatest value:—

R. *Tinct. Myrrhæ*
 Tinct. Krameriæ
 Tinct. Cinchonæ
 Tinct. Catechu ana ℥ss.
 Eau de Cologne ℥i. *misce.*

Fiat mistura. Signa—"A large tea-spoonful in a wine-glassful of water to be used as a mouth wash frequently."

STONE IN THE BLADDER.

In the case of the female the treatment of this affection is a simple matter in the majority of instances. Dilatation of the urethra by the blades of a stout pair of dressing forceps, or by an instrument devised for the purpose, should be performed, and if extraction of the stone is not easily effected after being seized by suitable forceps, it can be crushed by a lithotrite and removed at once. The writer years ago had several cases of stone in children, and no incontinence followed the dilatation of the urethra to the extent of admitting the little finger and exploring the bladder. Soft stones can be safely broken up by a pair of necrosis forceps, and the fragments extracted, taking care not to cause laceration of the passage or injury to the neck of the bladder. Large stones must be crushed with the lithotrite, but if of very great size and hard they may be removed by the vagina or by the supra-pubic method.

In males the operation is, of course, very different. Should solvent treatment have a chance? Nearly every surgeon answers this strongly in the negative, nevertheless there is unquestionably sufficient evidence to show that in a narrow minority of cases it should have a trial. As pointed out by Roberts it is absolutely useless in all cases where the urine is ammoniacal, and in all cases of oxalate of lime and phosphatic calculi, and it is only applicable in those cases of vesical calculi in which *the urine is acid, the stone not large, its composition known to be, or strongly suspected to be, uric acid.*

In a patient who has recently had an attack of renal colic followed by evidence that the stone has descended into the bladder, where the urine is acid, and where a former uric acid stone or uric acid gravel had been passed, the writer is satisfied that the only course open (in the absence of severe bladder disturbance) is to give the continuous alkaline administration a fair trial but it must be rigidly carried out as described upon page 897. He has satisfied himself often that strict adherence to this method will facilitate the passage of uric acid stones through the urethra, which might not otherwise have been voided, but, of course, such an opinion is not worth much if one only lets one's mind dwell upon the fact that the great majority of stones passed down the ureters into the bladder are expelled in the urine.

If upon sounding, a stone is struck, the generally accepted rule is immediately to consider whether the case is one for lithotripsy or lithotomy. It is difficult to decide the size of the calculus, but in the great majority of cases coming under the care of the surgeon this is already so large as to be considered out of the reach of solvents. The writer once got a clear tinkle from a stone not larger than a red currant. Perhaps one of the reasons why the solvent method meets with so little sympathy from the surgeon may be owing to the fact that the specialist does not, as a rule, get the cases in as early a stage as they are met by the physician.

There are sufficient cases on record to show that phosphate calculi may be dissolved by injections of diluted Nitric Acid in the bladder (1 of the dilute acid to 80), but the process is surrounded with such difficulties in carrying it out that it has been little practised. It may, however, be resorted to in the intervals of crushing such stones where phosphatic deposits are taking place, as they do sometimes with rapidity, upon the fragments before their emission. Alkaline injections into the bladder for uric acid calculi are not to be undertaken when the stomach answers the same purpose so readily. The solvent action is to be of use, as already pointed out, must be practically continuous, and must be carried out for many weeks. This can be done without any danger to health, as is seen at Vichy and other alkaline springs.

Notwithstanding all that can be said for the solvent treatment it is a very trivial minority of cases coming under the care of the surgeon in which it can be successful, and the practical question in the treatment of stone is to decide the question of crushing or cutting.

In children the cutting operation has generally been preferred but since the introduction of Litholapaxy by Bigelow, in which the stone is crushed and its fragments removed at one sitting, some boys who formerly would have been submitted to the cutting operation are now successfully operated upon by the crushing method and Marshal, Freyer and many others believe that the cutting operation, even in the case of boys, should be now seldom resorted to. It must, however, be remembered that the cutting plan in children is followed by such a very low mortality that it will be long before it will go out of fashion.

In adults, lithotripsy should have the preference for all cases in which the stone is not too large to be grasped by the lithotrite or too hard to be crushed. The older the patient the greater the reason for lithotripsy in preference to any cutting operation. Large stones should be removed by the supra-pubic method. Very hard uric acid or oxalate of lime calculi may resist the lithotrite, and then lithotomy must be resorted to; but, upon the whole, there cannot be any doubt that lithotripsy is all round a safer operation and the number of cases in which it is inadmissible is small. Stricture of the urethra and enlargement of the prostate are no barriers to crushing. The urethra may be gradually dilated by solid metal bougies up to No. 16 just before the operation, and with prostatic enlargement the washing out apparatus overcomes all difficulty.

For a very interesting account of the relative values of lithotripsy and lithotomy the reader may consult Freyer's "*Modern Treatment of Stone in the Bladder*."

Deformity of the urethra, as may be seen in rare conditions where some old injury or abscess has led to its cicatrization, may demand lithotomy. The scale between the two operations may

also be turned by a very unhealthy and irritable state of the bladder. Where there is evidence that the kidneys are diseased, and an operation is imperative, crushing is safer with any reasonably sized calculus.

Lithotripsy is now carried out, generally at one sitting, by removing all the crushed fragments and debris by means of a suction apparatus. It is considered necessary to give an anæsthetic or inject 1 or 2 drachms of a 4 per cent. Cocaine Solution. Much will depend upon the patient, upon the state of his bladder, and upon the size of the stone. Once the writer had to crush a small stone in a patient who could not bear an anæsthetic (before the days of Cocaine), and he was surprised to see how little pain need be inflicted during the operation. In cases where the crushing, except of very small stones, is to be carried out at one sitting, the use of the anæsthetic is necessary. The patient being placed upon his back, with the pelvis slightly elevated, and the operator standing upon his right, the lithotrite, well lubricated, should be passed gently into the bladder. Before operating it must be seen that the bladder contains at least a couple of hours' urine; if not 4 or 5 ounces of warm Boracic Acid Solution may be gradually injected.

As the lithotrite glides into the bladder the handle is raised and the female blade pushed gently down, so as to slightly depress the floor of the cavity. When this manœuvre is skilfully executed the stone often drops into the blade, and is seized in position by the male portion of the instrument and crushed. When this plan fails, the lithotrite, with its open blades, is turned from side to side or inverted so as to pick up the calculus from the floor of the bladder. This latter method suits best in all cases where the prostate is enlarged.

After screwing home the blades they are again separated, and any large fragments picked up in turn and crushed. The same lithotrite will do in most cases of small stone, but for large ones some operators prefer to crush first with a strong instrument, and then use a small one for the fragments.

The lithotrite should not be withdrawn till it is screwed tightly home. The evacuating catheter is then introduced, and the aspirator attached. A stream of water is sent into the bladder by a sharp squeeze of the rubber bottle and as the pressure is withdrawn, the water is sucked back, bearing detritus and small fragments with it, which fall into the glass reservoir. If the fragments are not all removable a second or third crushing of them may be necessary, using the aspirator after each operation, till every particle of the stone is removed when possible. With a very neat and careful operator no blood may be seen in some cases, and little irritation may result with small stones.

The after-treatment consists in washing out the bladder with a $\frac{1}{2}$ per cent. solution of Nitrate of Silver immediately after operation, a Morphia suppository, diluent drinks, rest in bed, warm baths, a few doses of Boracic Acid, and a restricted diet.

If cystitis follow, it must be met by the remedies detailed under its own heading.

Harrison has recently revised the old operation of *perineal lithotomy* by incising the membranous urethra and entering the bladder upon a fine gorget, and crushing the stone with a modified lithotrite. The operation is very suitable for large stones where there are prostatic difficulties.

Lithotomy aims at removing the stone by an incision into the bladder where it is uncovered by peritoneum, either through the perineum or above the pubes. Only the merest outline of these operations need be given with the view of refreshing the student's memory.

The lateral operation is performed by incising the membranous and prostatic urethra and the left lobe of the prostate.

After the rectum has been emptied, and the patient placed upon a suitable table in the lithotomy position, by the assistance of bandages or anklets or Clover's crutch, and under the influence of an anæsthetic the staff is passed into the bladder and made to strike the stone. The bladder should be moderately full. The staff is then entrusted to a reliable assistant, who holds it firmly & hooked under the pubic arch. The operator introduces his finger into the rectum, and takes the bearings of the various regions feeling for the apex of the prostate and the staff, and, finding an satisfactory, he withdraws the finger again.

An incision about three inches long is made in the shaven perineum, commencing about one inch and a half above the anus just to the left of the middle line, and carried outwards and downwards towards the ischial tuberosity, about one inch and a quarter outside the anus, through skin and superficial fascia but without striking the staff, which is to be felt for by pressing the left index finger into the upper end of the wound. As soon as the groove is felt, the point of the knife is inserted into it, and the membranous portion of the urethra divided as the knife is pushed along the groove till the bladder is reached, cutting the left lobe of the prostate and neck of the bladder. If the stone is a large one, the incision may be increased as the knife is withdrawn by allowing it to leave the groove, or by thoroughly lateralising it, with its back kept firmly in the groove. If the straight staff has been used, the operator at this stage takes the staff in his left hand after inserting the point of the knife into its groove, and rotates it till the proper angle is obtained, when the prostate is divided as the knife enters the bladder.

After the withdrawal of the knife, the left index finger is introduced along the staff into the bladder, and when the stone is touched the staff may be removed. A pair of lithotomy forceps is now guided along the finger, the stone seized, and extracted. The gush of urine following the withdrawal of the left index finger generally carries the stone between the open blades of the forceps.

A careful search is then made for a second stone, which, if present, is also removed.

The patient should be put to bed with a pillow under his knees, and a good draw sheet. An anodyne may be given, and a light diet administered.

The median operation, which is becoming less employed, is only suitable for small stones. After the patient has been placed in the usual lithotomy position, a curved or rectangular staff, with a median groove, is passed into the bladder, and held by an assistant as in the lateral operation. The operator then passes his left index finger into the rectum, with its palmar surface upwards, and the tip resting against the apex of the prostate. A long, straight bistoury is entered half an inch in front of the bowel, passed through the raphe with its back to the bowel, till the staff is reached at the apex of the prostate and after being pressed for a short distance towards the bladder, it is made to cut upwards, dividing the membranous portion of the urethra to the required extent. The finger is then introduced into the bladder on a blunt probe, and the stone caught and extracted as in lateral lithotomy.

The supra-pubic operation is now generally performed for large calculi in the following manner:—The urine is drawn off by the catheter, and the bladder is filled with warm Boracic Lotion, and this is kept in by a ligature round the penis. The rectum is filled by a thin rubber bag, into which 10 to 15 ozs. of warm water are injected. By these means the fold of peritoneum is lifted high up out of danger from the knife, and the bladder pushed up in the pelvis. An incision about three inches long is made in the middle line above the pubes through the linea alba, and by the finger-nail, a blunt director, or the handle of the scalpel, the fat is dissected aside till the bladder is reached. This is fixed by a tenaculum, and opened behind the pubes, so as to make an entrance for the finger, which, after measuring the stone, is withdrawn, and the opening enlarged to the required extent, or the opening may be enlarged, the finger acting as a director, after which the stone is extracted by suitable forceps. As regards the after-steps there is much diversity of opinion, some operators simply leaving the bladder and skin wounds open, others insert a long rubber tube into the bladder, others suture the bladder wound, and some insist upon a catheter being tied in the urethra. Attention should be paid to the posture of the patient, so as to ensure the most thorough drainage.

STONE IN THE KIDNEY.

The treatment of this generally very painful affection will depend upon the stage of the disease or upon the symptoms present when the case first comes under notice.

Renal colic, or the pain produced by the calculus finding its way into the pelvis of the kidney or into the ureter, is best relieved by a hot bath given as soon as possible after the commencement

of the attack. The patient should remain in the bath under the charge of a discreet attendant till the full antispasmodic effect of it is observable, i.e., till he complains of weakness or a feeling of syncope. This is undoubtedly the best routine treatment to adopt whenever it is available. Under its influence the spasm of the ureter may relax, and small calculi may find their way speedily into the bladder. Opium in small doses (15 minims of the Tincture) may be given every half hour for 3 or 4 hours if the agony is severe, and this drug may be commenced whilst the bath is being prepared, and it may be continued during immersion.

Morphia hypodermically gives the speediest and most effective relief, and it may be resorted to immediately when the pain cannot be tolerated. One-third or one-half grain may be injected under the skin in the neighbourhood of the affected kidney, but, upon the whole, it is wiser to wait until after the hot bath has been taken, when, if relief be not obtained, it may be injected as the patient is put to bed with warm water bottles applied to his loins.

The physiological effects of the drug should be produced, and as these require very large doses in many cases, the writer's routine practice is to give first a full dose of Whiskey (1 to 2 oz.), and then the hypodermic of morphia, combined with two minims of the B.P. Solution of Atropine. With these precautions, full doses of the drug may be given safely. Moreover, the action of the atropine assists that of the morphia, whilst it prevents any depressing effect upon the heart. Where the agony is intense, Chloroform may be inhaled. In patients subject to attacks of renal colic it is a good plan to advise a large warm water enema followed by a morphia suppository ($\frac{1}{2}$ grain), to be used as soon as the attack threatens, whilst the bath is being prepared. The temperature of the bath should commence at 100° F., and be raised to 104° or 106°. A hot pack may be resorted to in the absence of the bath.

Hot stupes to the loins, hot poultices, and cupping may be resorted to with advantage. Manipulation of the ureters through the abdominal walls and inversion of the body have sometimes given good results.

Local anodynes have little effect; and the new analgesics, as Antipyrine, Exalgin, &c., generally fail entirely.

During the intervals of the attacks an attempt may be made to carry out Roberts' plan of dissolving the calculus. This need only be thought of where there is reason to believe that it consists of uric acid urates, or cystine, all of which are soluble in alkalis. If the stone should consist of oxalate or lime the alkaline treatment will do no harm, and in all cases where the urine is acid the alkaline solvent method should have a full and fair trial, especially as it can do no harm, and in the majority of cases no other plan is available. The writer believes that he has obtained good results by the use of alkalis in full doses.

Roberts insists that to be of any use, the urine must be kept *continuously* alkaline for long periods. The dose must be given every three hours at least during the waking hours, and during the night when the patient is awake. The Citrate and the Acetate of Potash, in doses of 40 to 60 grains dissolved in 3 or 4 oz. water, are the best alkalis, and he advises that the citrate from the shops is not to be relied upon, but that it should be prepared fresh by neutralising the crystallised bicarbonate with crystallised citric acid, as in the following formula:—

R. *Potassii Bicarb.* ℥xx.
 Acidi Citric. ℥xiv.
 Aque Destill. ad ℥xx. misce.

This yields one drachm of the citrate of potash in each fluid ounce the dose for adults being 6 to 8 drachms in a claret-glassful of water, and for children half this amount.

Hæmaturia and other symptoms, when they show themselves, must be treated by absolute rest and the appropriate remedies mentioned under their separate headings. (See Hæmaturia Pyonephrosis, Hydronephrosis, Pyelitis, &c.)

Surprising results may be obtained in many cases by *absolute rest in bed* for several weeks, during which time the stone may become encysted, and the writer has found all trouble to cease and never to return by this method, the calculus evidently having become fixed in one of the calyces of the kidney.

Here again the surgeon has derived valuable help from the X Rays. Many instances are now on record where the existence of a renal calculus has been positively demonstrated by aid of a radiograph. Renal puncture by a long needle, as an aid to diagnosis, has been shown by Mr Myles, of Dublin, to be a dangerous and unsatisfactory proceeding, and is now rarely employed.

If the symptoms warrant a positive diagnosis, and by their severity render the patient's life unbearable an attempt should be made to remove the stone after prolonged rest has failed. Where there is no evidence of any suppuration or disorganisation of the renal organ present the operation of Nephro-lithotomy has given brilliant results in some cases. Its mortality when performed early is exceedingly low in all cases where there is no disorganisation of the gland. It is practically the same operation as nephrotomy, only, owing to the absence of the great enlargements usually met with in cases where the kidney is enlarged or extensively diseased, the operation is often more difficult.

The operation itself consists in making a free incision into the kidney. The organ is reached by making an incision in the lumbar region between the last rib and the iliac crest at the

external border of the erector spinae. When the kidney is reached it is if possible dislocated into the wound when it can be carefully palpated, and the position of the stone generally detected. A free incision is then made into the substance of the organ from the convex border, in a vertical direction, and the stone removed after which the wound in the kidney is closed by a few deep catgut sutures, which effectually arrest hæmorrhage. The wound in the abdominal wall is then closed, drainage being provided for.

Where extensive disorganisation of the kidney is found to be present the operation of nephrectomy or removal of the whole kidney may have to be carried out. If this is contemplated from the first it may be performed by abdominal section in the middle line or by an incision through the linea semilunaris, or if a nephrotomy or a nephro-lithotomy is attempted at first, the entire organ can be removed through the lumbar incision by modifying the procedure when the examination shows that the kidney itself must be removed.

In those rare cases where a calculus blocks up one ureter the opposite organ having been rendered useless by a similar event some time previously, there is little hope for the patient unless the recently-formed stone descends into the bladder. In such an instance abdominal section may be imperative in order to give the patient the only chance for his life. There have been recent successes following this bold procedure. The writer had such a case lately, but unfortunately the calculus descended into the pervious ureter during parturition, and an abdominal section under such circumstances was regarded as hopeless by the patient's accoucheur.

STONE IN THE URETHRA.

With a calculus impacted in any portion of the passage, it is well not to think of pushing it back into the bladder until other measures fail. By skillful manipulation a small stone may be pressed forward by a gentle kneading movement, executed by grasping the penis between the fingers if in the penile portion of the urethra.

By stopping the flow of urine for a little, and suddenly causing a quick contraction of the bladder and accessory muscles, it may be squirted out if the obstruction is not complete.

A pair of urethral forceps may be passed down to the impediment, and, aided by external manipulation, the operator will often succeed in seizing it.

A scoop or loop, such as is used for the removal of foreign bodies from the ear, may be passed beyond it, care being taken by external pressure to prevent its return to the bladder.

If failure attend these methods, an incision may be made and the stone pushed out from behind by a probe or catheter introduced into the wound. When far back the median lithotomy operation may be tried. In adults it is better, when extraction fails, to push

the stone back into the bladder by a blunt bougie, or by a catheter with the opening at the very point. When forced back it can be easily crushed by a fine lithotrite in the bladder.

As the stone is brought forwards, if extraction by scoop, forceps, or external manipulation succeeds, it may be found to stick fast in the fossa navicularis, from which it may be only possible to release it by incising the meatus.

If an incision be made down upon a stone impacted in the anterior part of the urethra there is considerable danger in the urethral wound refusing to heal, and a permanent fistula may result. Hence most surgeons insist upon the wisdom of pushing the stone backwards as far as the perineum, holding it there by the pressure of the finger, and cutting down upon it in the middle line through the aid of the staff or director by which it was pushed back.

In neglected cases, where extravasation of urine has already occurred, free incisions into the perineum and surrounding tissues must be made without delay, after which the calculus may be removed by cutting down upon a staff passed as far as the obstruction.

STRANGURY.

The cause must first be found out and removed when this is possible. Stone in the bladder, ureter, or urethra, or inflammation of these parts may exist, and their proper treatment will be found detailed under their separate headings. (See Stone, Cystitis, Bright's Disease, &c.)

Where the symptoms are caused by the external or internal use of Cantharides, or by the administration of Copaiba, Sandal Wood, or Turpentine, the use of the drug should be instantly suspended.

A good hot bath or hot sitz bath, with warm diluent drinks, or iced water, a Morphia suppository in the rectum, followed by continuous hot fomentations applied to the perineum, and, in very painful cases, a hypodermic injection of Morphia and leeching may be tried. Blisters should be used with great caution on patients the subjects of Bright's disease or bladder affections, and in young or debilitated folk. When necessary in these cases they should not be kept on for more than two or three hours, and after their removal a poultice should be applied.

STRICTURE OF THE GULLET.

Under Cancer of the Gullet (page 117) the treatment of malignant stricture is described. Under Oesophagus, Stricture of, upon page 627, the treatment of simple stricture is detailed.

STRICTURE OF THE INTESTINES—See under Intestinal Obstruction (Page 476, and also on page 121)

STRICTURE OF THE RECTUM—See under Cancer of the Rectum (Page 122)

STRICTURE OF THE URETHRA.

The method of intermittent or interrupted dilatation is applicable to the great majority of organic strictures through which an instrument can be passed.

Though most successful in strictures of recent formation, owing to its painlessness, simplicity, safety, and convenience, often the surgeon gives it a trial when the aspect of the case, its great duration, and the density of the tissues entering into it, and other characteristics indicating some of the more severe operations, might tempt him to begin with a section of the urethra. It is, moreover, the practice selected in those cases where, owing to serious disease of the kidneys, a radical cure of the contracted region is neither possible nor its attempt commendable.

Various instruments are used, and it need hardly be insisted upon, that, in the absence of retention of urine, catheters should not be employed. Differences of opinion exist as to the preference to be given to soft or solid metal bougies, some surgeons insisting upon the routine employment of one kind to the exclusion of the other. It will be safe to adopt, under ordinary circumstances, the following practice, especially if the operator has not much experience—*i.e.*, to employ soft gum-elastic bougies or, better, a bulbous black French bougie when the opening is as small as a 6-8 English, or less, and to always use metal ones for wider strictures.

There is considerable danger in passing small metal instruments except by the most experienced. Heavy, solid bougies for all sizes of stricture are better in skilled hands than gum-elastic instruments for interrupted dilatation, though it will be safer to begin with the latter in narrow strictures.

The old-fashioned, highly-polished bellied sounds of Sir Henry Thompson are the best. They have a wide curve, and are so tapered that the widest part of the instrument fills the stricture after it has been dilated by the thinner portion, as it is gently pressed on towards the bladder. Tortuous strictures cannot be safely treated with rigid instruments till after partial dilatation by pliable ones.

Having placed the patient in the best possible condition of health, and having his bowels cleared out (and a warm bath given in some cases), he is sent to bed for a few hours earlier than usual, and the treatment may be inaugurated. This latter precaution is a wise one if the operator has not had any previous experience of the patient's power of tolerating urethral interference. It will be well to begin the treatment after he has got warmed in bed, and where he can remain till next morning. In this way rigors, &c., may be prevented till the patient gets accustomed to the use of instruments. (See under Urethral Fever.) At subsequent dilatations this will be unnecessary. It will, however, be always necessary to caution the patient against walking or other exercise, and against exposure to chills for some hours after the passage of instruments.

Beginning with an instrument that will just slip through the stricture upon the lightest pressure, the next size is to be gently passed, and sometimes the succeeding size may be manipulated through at the first sitting. Five minutes will be found a sufficient time for the last bougie to be left in the stricture. Force, in the ordinary sense of the word, is never to be used, and it is better to be content with making gradual headway. The bougies or sounds should be warm and well lubricated with Lard, Vaseline, Carbolic Oil, or Lund's Lubricating Oil. The writer prefers a thick Glycerin of Borax for this purpose, and has never been disappointed with it—it never becomes rancid, and it is always aseptic, and never irritates the urethra.

The length of the intervals between the sittings is to be regulated by the amount of dilatation accomplished, and by the tolerance of the urethra. Every third day till headway is made, then every seventh day is a safe rule. In the case of a stricture which contracts rapidly, it may be safely attacked twice a week.

At the commencement of each sitting it is well to begin with a size smaller than the one last employed at the former sitting. Any irritation of the bladder or urethra should be subdued before commencing or resuming operations.

As the stricture becomes widened, and the larger sizes can be passed it is an excellent plan to leave the instrument in for 10 to 20 minutes before finishing up the sitting; but this practice only excites pain and irritation till the stricture is accustomed by weeks of interrupted dilatation to tolerate the presence of the bougie.

The sittings should be continued till a No. 15 English instrument can be easily passed. To stop at a No. 12 is a mistake, as inevitable shrinkage soon follows. It is the non-observance of this rule which leads to failure in the hands of most men. Though the stricture cannot be regarded as cured in the great majority of cases, nevertheless, by dilating the urethra up to its fullest capacity, the very best results are obtainable, and in some cases no narrowing may be detected for years.

It is essential, however, that the patient be taught to pass at least a No. 12 English gum-elastic bougie every month for three or four months, then every three or six months, returning once a year to have the largest (No. 15) size introduced by the surgeon.

Where the stricture is very narrow at the start, and especially if very tortuous, this plan will sorely tax the operator's patience; and in those cases where it rapidly contracts between the sittings it may have to be given up. In such cases the writer, when formerly engaged in surgical practice, made it a rule to start the treatment by continuous dilatation, and afterwards resort to the interrupted. This plan succeeds admirably in many bad cases, and by a patient trial of it, cutting operations are seldom required.

By continuous dilatation the operator brings a new element into his treatment and the continual, steady pressure of the face of the stricture against the retained bougie soon leads to the establish-

ment of important changes in the inflammatory or cicatricial tissue entering into the formation of the stricture.

The patient is put to bed after a warm bath, and twice a day 10 grs. Boracic Acid are administered after food. This drug is an important branch of the treatment, as it renders the bladder perfectly aseptic, and robs the method of many of its objections. Creosote, 2 minims 3 times a day, may be substituted for the acid when the stomach is irritable.

So prepared and every attention to the patient's health and kidneys having been paid, a soft gum-elastic catheter is passed through the stricture. It is tied in and allowed to remain for 24 or 48 hours, when a larger one is substituted for it. This is again changed at the end of two or three days, and so on till the full size is reached. The bone end of the catheter should be removed and a small plug of wood inserted into the calibre of the instrument. The catheter should be kept free of the neck of the bladder, it may be pushed home as the urine is required to be drawn off every four hours; after this is accomplished, it may be withdrawn for one or two inches, so as not to cause needless irritation to the neck of the bladder. The plug of wood must be carefully inserted each time into the end of the instrument.

This plan as just described is followed by relapse so often that it is now seldom carried out; but if it be discontinued as soon as, say, No. 7 can be passed, the treatment then can be carried out by further interrupted dilations by polished solid metal sounds. Its great value consists in starting treatment in the case of very tight tortuous strictures, where the passage of small-sized rigid instruments is very dangerous from their liability to form false passages.

The plan of treating strictures by rupture or forcible dilatation is carried out in two ways. An instrument consisting of two blades folded together, so as to take the shape of an ordinary sound, is passed into the urethra through the stricture, when the blades or lateral halves are slowly caused to separate by turning a screw on the handle. The stretching ruptures the stricture, as stricture tissue will not yield to any appreciable extent. The operation is carried out at one sitting, lasting over 15 to 30 minutes.

A speedier plan is that sometimes known as Divulsion, in which a somewhat similar instrument is used, but the force is suddenly applied by thrusting a wedge or rod of metal between the parietal halves of the dilator. The sudden expansion of the blades splits or rips open the fibrous tissue of which the stricture is composed.

Both methods are very dangerous, being liable to be followed by the worst complications, and when immediately successful are generally followed by speedy relapse.

The writer has witnessed the practice of a plan in favour with the older school of surgeons, which, though dangerous and objectionable, nevertheless sometimes gave brilliant results in the treatment of recent soft elastic strictures. He tried it on himself many years ago, and was surprised to find how easy it

successful it was. A moderately wide stricture, say one admitting a No. 6 or 5 English solid tapering or bellied sound, is dilated by the next size, and one such instrument after another is passed, the force gradually increasing, though never amounting to anything like strong pressure upon the handle, till a No. 12 is passed at one sitting. The number of strictures to which such heroic treatment would be applicable must be very limited.

Urethrotomy is the operation of cutting through the stricture. This is done internally from the urethra, or externally by cutting down upon it through the skin from without.

Internal urethrotomy is applicable to strictures near to the meatus, to those which contract rapidly after dilatation by bougies, to dense cartilaginous or narrow bridle strictures which cannot be dilated without the use of a force being applied which is not safe, and to strictures in patients subject to rigors and urethral fever of a severe type. Internal should always be preferred to external urethrotomy where possible.

A great variety and number of ingenious instruments are used, each operator selecting one which carries out some requirement that he considers essential to success. These may be divided into two classes—i.e., those designed to sever the stricture from before backwards, and those which are first passed through the stricture, which is then divided as the instrument is withdrawn, cutting from behind forwards.

In very narrow strictures of cartilaginous hardness the former kind of instrument is employed. A fishform guide-bougie is first passed through the stricture into the bladder. Upon this a hollow sound is introduced through the narrowed part, and by means of a shielded blade guided upon a contrivance attached to the halves of this sound, the narrow stricture is divided to the required depth as the blade is pushed against the stricture towards the bladder, cutting from before backwards.

Where the stricture can be dilated to the size of a No. 5 instrument, the urethrotome of Thompson, Civiale, or Otis, is passed through it, and as the instrument is withdrawn the concealed blade is caused to incise the narrowed part for its entire length, the depth of the incision and the "tautness" of the parts being regulated by various mechanical contrivances designed for the purpose. Hill's instrument can be used when the stricture only admits a No. 2. The stricture must be divided on the floor of the urethra and through its entire depth, but care must be taken to leave intact the healthy vascular or erectile tissue lying external to it. In using Thompson's urethrotome the operator gets great assistance by feeling the resistance of the tissues and the progress of the blade, by grasping the penis from the outside with the fingers of the left hand.

After the operation of cutting, a large solid metal sound (No. 14 English) is put into the urethra, and permitted to find its own way into the bladder by gravitation. This gives a practical proof of

the completeness with which the stricture has been divided and should the sound fail to enter the bladder without pressure a second incision of the parts may be considered advisable. Upon withdrawal of the sound the largest sized metal catheter is inserted, and the bladder very thoroughly emptied of all urine. It is a mistake to attempt to tie in a catheter. The patient is placed in bed, gets a Morphia suppository and abstains from drinking liquids, and is kept very warm so as to encourage the action of the skin, whilst a few bits of Ice are used to relieve thirst. In 6, 8, or 10 hours, when he can hold his urine no longer, he is placed in a hot bath and permitted to micturate. Rigors are to be anticipated by a full Opiate, Whiskey, and Quinine, and the bowels which should have been purged before operation, are allowed to remain locked up for the first four days.

The following combination may be used to prevent rigors and fever:—

R. Quinina Sulphatis gr. vj.
Pulveris Doveri gr. xii.
Acidi Boracici gr. v. misce.

Fiat pulvis. Mitte tales vi. Signa—"One to be given immediately after the operation, in a table-spoonful of whiskey, and repeated in three hours, and again in six hours if necessary."

The following may be given where large doses of Quinine cannot be tolerated:—

R. Liquor. Morphina Hydrochlor. ℥ij
Phenazoni gr. xl.
Cocaina Hydrochlor. gr. vi.
Aqua Chloroformi ad ℥iij. misce.

Fiat mistura. Capiat cochleare medium secundis horis et paululo aqua.

Hæmorrhage may be troublesome at any time within a week after the operation, and is especially liable to come on after erections if the incision has been too deep. If from the deep portion of the urethra, firm pressure and an Ice-bag or the crutch of Otis may be used. If very severe, external urethrotomy should at once be performed, and the wound tightly packed with gauze around a catheter, as recommended by Myles, Fenwick, and others. Suprarenal Extract has been strongly recommended in urethral hæmorrhage from this or other causes. If from the penile portion of the canal a firm catheter or lithotomy tube may be passed, and a bandage placed round the penis so as to com-

press the bleeding surface against the instrument till some effort is made at repair.

Extravasation of urine, urethral or septic fever, pyæmia, cystitis, epididymitis, urethritis, or kidney trouble, must be dealt with promptly if they show themselves.

About the seventh day the patient, in a warm bath, should have a well lubricated soft gum-elastic bougie (No. 12 English) passed through the urethra, and he should be confined to bed till this period. About every three days for the next fortnight will suffice for the passage of the bougie, and at the conclusion of the treatment the patient is taught to do this himself, the after-management being exactly the same as if the operation of uninterrupted dilatation had been carried out.

Where long-standing bladder troubles cause fetid or ammoniacal urine and pus to trickle over the wound, the operation of draining the bladder by means of a perineal wound is sometimes considered, but the very marked and reliable effects of Boric Acid when given internally will sometimes do away with this necessity.

The operation of internal urethrotomy is indicated in elastic or resilient and in very irritable strictures, especially when in front of the scrotum. MacGillivray, Otis, and others have devised instruments for cutting the stricture while on the stretch.

In *external* urethrotomy the stricture is reached from without, and there are various operations to suit the requirements of the different cases. The cases in which the operation is indicated are those generally associated with urinary fistula and a dense unyielding stricture, and those instances in which a portion of the urethra is practically obliterated by a tortuous narrow stricture, through which it is impossible to get any instrument towards the bladder, and in which internal urethrotomy would be dangerous or impossible.

When an instrument can be introduced through the stricture into the bladder, Syme's operation is the one usually selected. A staff, grooved upon the convexity of its curve, which is about the size of a No. 2 English catheter, is passed through the stricture into the bladder. The groove is in the middle of the curve, and thus ends abruptly in a broad shoulder which marks the beginning of the anterior portion of the staff, which is about the size of a No. 12 English from the shoulder to the handle. With the patient in the lithotomy position, and the narrow grooved part of the staff through the stricture, the broad shoulder being held against its face, the operator cuts down on it from without by a median incision, enters the groove with his knife and divides the stricture in its whole extent, after which a catheter is passed upon a probe acting as a guide into the bladder. A fine gorget may be used to incise the urethra in the direction of the bladder. A catheter is tied in for the first three or four days, and a bougie or sound passed every second or third day till the perineal wound heals.

Wheelhouse's method is the one generally selected when it is

found impossible to get any guide or instrument into the bladder through the stricture. With the patient in the usual lithotomy position a staff is passed down to the stricture and held there, the button-like point of the staff bearing down against the face of the narrowed tunnel. A median incision is made down to the skin and the urethra fully divided for nearly an inch. The edges of the wound in the urethra are held apart by sutures or forceps and after careful sponging a search is made for the opening of the mouth of the stricture. When this is obtained, a grooved director is passed through it into the bladder, and upon this instrument the tortuous, narrow stricture is divided to its whole extent by a narrow knife or gorget. A large catheter is then passed down the urethra, guided into the incised part, and pushed gently into the bladder, where it is retained, as in Syme's operation.

When it is considered advisable to open the urethra *behind* the stricture, the operation of perineal section is selected in those cases where it is impossible to pass any guide into the bladder.

In the lithotomy position, the operator places his finger in the rectum upon the tip of the prostate. A sharp-pointed bistoury is plunged into the middle line of the perineum, half an inch in front of the anus, with its back towards the bowel, and it aims at opening the distended urethra in its membranous portion, just at the tip of the prostate. When this has been accomplished a grooved probe is passed through the wound into the bladder, and upon this a tapering gorget is guided.

When the bladder has thus been successfully reached, two ways are open for dealing with the stricture—a probe passed into the wound may feel for the posterior opening of the stricture, through which it may be passed, and which may then be divided from behind forwards, or an instrument may be inserted down the urethra, and its point cut upon till it appears in the wound. When this has been achieved, a large catheter should be passed down the urethra, and guided into the bladder, and the most patient dilatation by the passage of sounds must be kept up long after the healing has been established, as such strictures are very prone to contract.

Sometimes it is only possible to effect an entrance into the bladder from behind the stricture, without being able to deal with the latter, and it is astonishing to find afterwards how easily a narrowing, which had foiled all attempts at catheterisation, can be made to yield after a few days rest following perineal section. Shield successfully sutures the urethral wound after perineal section.

Excision of the strictured portion of the urethra has been tried but very generally with indifferent results. Wolfier found that the mucous membrane was reproduced upon a urethra from which he had excised an innodular stricture. He uses the mucous membrane obtained from the "stomach of the frog, the bladder of the rabbit, or from the oesophagus of the pigeon, which are at

easily separable from the muscular layer of the animal, and which all adhere in the human subject, and when properly placed retain their vitality.

Electrolysis (3 to 5 milliamperes) has been employed for the cure of urethral stricture, and improvements in the method have demonstrated that it is safe and often very successful. The negative electrode—a metal tipped gum-elastic bougie—is passed down to the face of the stricture, against which it is held for 15 to 30 minutes, the large moist positive electrode being in contact with the lumbar spines. The current softens and causes decomposition of the cicatricial tissue, and permits the negative electrode to pass into the bladder often in 20 minutes without pain. The operation must be several times repeated till the largest instrument easily passes through into the bladder.

Fort uses linear electrolysis by means of a current of 20 to 40 milliamperes, and an instrument constructed like a *Maisonneuve's* urethrotome. The results are not satisfactory.

STROPHULUS.

The treatment of this affection should be that of a mild form of lichen in infants. Some authorities regard it as identical with lichen, the treatment of which is given upon page 514.

In the infant the affection is regarded by *Morris* as a form of *milharia rubra*, "red gum," caused by too warm clothing. It generally yields rapidly to improved clothing, feeding, and aperients, with some mild alkali, as *Fluid Magnesia*. Locally, any mild unirritating sedative, like the *Oxide of Zinc*, dusted freely over the part, does best.

Strophulus albidus, or *milium*, must be treated in a different way. The small yellowish-white masses consist of dried sebaceous matter covered over by a layer of epidermis and corium, and, as they appear on the eyelids and forehead, may be disfiguring. A fine incision should be made by the point of a lancet or small tenotomy knife, and the contents squeezed out.

STY.

Preventive treatment is of importance, and *Payne* considers that the condition is often produced by infection from the scales of seborrhoea falling down upon the eyelashes from a scurfy scalp. The treatment of the primary affection by mild antiseptics is therefore essential in all recurring cases.

In the early stages epilation will generally at once remove the trouble. By plucking out the eyelash, any matter that may have already formed is thus left free to discharge itself through the minute opening. If matter has not formed, this method may prevent it. A needle dipped in pure Carbolic Acid may be applied to the spot after the removal of the hair. Nitrate of Silver is generally used for this purpose, but it is very painful, and may increase the swelling.

Poultices in the neighbourhood of the eye are very unsatisfactory. Hot fomentations are less objectionable. A very weak Spirit or Carbolic Lotion is preferable, though it is not advisable to cover this in with oiled silk. The relationship of the sty to pus gives the indications for general and local remedies, and practice or any other applications, especially if moist and warm, have a tendency to multiply the local gatherings of pus, if the retained vapour arising from such applications is not speedily permitted to evaporate. Puncture (after cocaine) with the point of a fine narrow-bladed tenotomy knife or cataract needle generally gives immediate relief when matter has formed.

A weak Ointment of the Yellow Oxide of Mercury (6 grs. to 100) is the best after-treatment in all cases, and it appears to prevent further formations if properly used.

The following ointment may be used with benefit when the condition threatens to return:—

R. *Cocainæ Purif.* gr. iv.
Hydrargyr Oxidi Rub. gr. iij.
Vaslini Alb. ℥vj. *misc.*

Tere bene et fiat unguentum. Signa—"To be smeared on the margin of the affected lid three times a day."

SUFFOCATION.

The treatment of this condition will depend upon the cause which must, of course, be immediately removed. Foreign bodies in, or constrictions around, the air passages call for instant remedying. Tracheotomy may be resorted to where the obstruction is above the larynx and cannot be removed. The various methods of performing artificial respiration are described under the article upon Drowning, page 224. (See also under Asphyxia and Poisoning by Chloroform.)

SUNSTROKE.

Preventive treatment will embrace attention to clothing, which should be always as light and cool as possible, open textured woollen garments next to the skin being essential. Excesses in eating and drinking, indulgence in alcohol, violent exercises and constrictions about the throat must all be guarded against, and in the close hot nights nothing is of more importance than free ventilation.

Instant transference to the shade in the open air, with removal of outer clothing and all constrictions about the neck, throat and chest, is the first step. In the pure syncopal or exhaustive variety of insolation this may be all that is necessary, with bathing of the face and hands in cold water in mild cases; but where the symptoms are pronounced the cold downe should be freely used.

and in cases of hyperpyrexia, life can only be saved by a free use of it. In such cases the patient must be treated upon the spot where he falls by the liberal application of cold water, in the form of douche, or cold affusion, the object being to rapidly reduce the temperature of the body by extracting the heat from it by cold water or ice, as in a case of hyperpyrexia in acute rheumatism. The temperature should not, however, be permitted to fall too low. A reduction from, say, 110° F. to 101° or 102° is better than a reduction to 95° or 90° , as some recommend. If there be evidence of great cardiac failure, stimulants may be required, but they should be used with great caution, and the horizontal position rigidly maintained. If removal in such cases is necessary before the urgent symptoms have subsided, it should be accomplished upon a stretcher.

Where the symptoms continue and repeated affusion is necessary to keep the temperature from rising, the thermometer should be kept in the rectum, so as to enable the physician to keep the body heat a little above the normal. Artificial respiration may be needed, and Nitrite of Amyl or Chloroform may be used if convulsions occur.

Copious enemata of iced water have occasionally been found useful, and they may be resorted to in conjunction with cold affusion or the cold bath, or used alone where from any reason these cannot be employed.

After the hyperpyrexia has been combated, symptoms are to be treated as they arise. Headache may be relieved by the ice-cap, by sinapisms or blisters behind the ears or over the occipital region or neck; constipation by smart Saline purgatives, and any remaining febrile temperature by small doses of Antipyrine, to which Digitalis and Quinine may be added.

Strong purges and bleeding are seldom indicated, and they may do serious harm. The same remarks apply to opium or hypodermic injections of morphia. In the after-treatment no animal food should be given for days, and absolute rest in bed must be maintained.

Meningitis and other troubles, should they follow, are to be met by appropriate remedies. As recovery is often imperfect, and followed by an irritable condition of the cerebral centres, Bromides will be indicated, and in some cases, owing to the increased susceptibility to heat, removal to a cold or temperate climate may be imperative, with avoidance of mental work and all sources of worry for a considerable period. Prolonged muscular exercise is also to be guarded against, and the use of alcohol strictly forbidden.

SUPPRESSION OF URINE.

If this be caused by the degeneration of the kidney, as it sometimes is, in the last stages of renal affection, the proper treatment will be that of Bright's Disease, pages 83 to 92.

If the suppression follows the impaction of a calculus in the ureter, this must be promptly treated by the various measures mentioned upon page 895, under Stone in the Kidney.

When the condition results from operations on the genito-urinary tract see under Urethral Fever.

When suppression follows the internal use of such agents as Cantharides and Chlorate of Potash, &c., the measures mentioned under Strangury will be indicated.

When the condition depends upon active congestion of the kidneys, the result of a sudden exposure of the heated body to low temperature, the proper treatment will lie in the use of those remedies calculated to restore the equilibrium of the circulation—hot baths, diaphoretics, warm poultices, sinapisms, or cupping to the loins. In every case the treatment will resolve itself into a removal or amelioration of the cause. When the *anuria* fails to respond in a short time, *uræmia* comes gradually on, and the remedies mentioned in detail under Bright's Disease, upon page 84, will be demanded.

These may be summarised as agents which will hasten elimination of urea and other products by the bowel and skin, as *Salut. Cathartics*—i.e., Sulphate of Magnesia in full and oft-repeated doses, the blanket, hot air, vapour or hot water baths, the hot pill, Pilocarpine, &c. No reliance whatever is to be placed upon diuretics which may seriously intensify the mischief.

In acute cases, as in active congestion from a chill, alone or associated with pneumonia, or with congestion of the lungs or acute bronchitis, a free blood-letting by opening a large vein, and making a rapid impression upon the circulation, may save life. In less urgent cases wet cupping over the kidneys is recommended. The writer, however would advise blood-letting from the arm if the case looks so serious as to at all justify the removal of blood.

SUPPURATION—See Abscess (Page 12)

SWEATING—See Perspiration, Excessive (Page 669)

SYCOSIS.

The treatment of this affection in late years has been much simplified by the advances made in its pathology. It has been demonstrated that two well-marked forms exist. The first is the hyphogenetic variety of *Unna*, or the old *tinea barbae* or *tinea sycosis*, and is really a true ringworm of the beard produced by the parasites which cause the different varieties of *tinea*. The second form is the coccigenetic, which is produced by the presence of pus cocci. Both are markedly contagious, and are caused by infection through the use of infected brushes, &c.

The treatment of the purulent form will be first dealt with.

The first points to settle are whether shaving, clipping or epilation, or allowing the beard to grow, is the best practice. The

hairs should be clipped close with great care and nicety by a sharp-pointed pair of scissors when the case is seen early. Later, epilation must be resorted to, and the loose hairs removed by forceps one by one every day.

The first step in the treatment will be the removal of all crusts or scabs before even clipping or epilation can be performed. A starch poultice is undoubtedly the best application for this purpose when it is properly made. Brocq advises that the starch for a poultice be first blended thoroughly with precisely the proper quantity of tepid water to form a paste. Boiling water is poured on to the paste, and the mixture left upon the fire for about one minute, being very briskly stirred to ensure its being thoroughly homogeneous. It may be then spread upon some soft, flexible fabric, and applied to the part. A little Boracic Acid (10 per cent.) added to the dry starch is a great improvement.

After the removal of the poultice the part may be smeared over freely with oil, and another poultice or a good sponging with hot water may be applied in order to clear away all crusts, after which the hair may be clipped and any loose bristles removed by the forceps. In this way most of the purulent points will be evacuated; any others may be incised with the point of a sharp lancet. The application from which the writer has obtained the most benefit is a Carbolic Oil (1 in 5 or 6). A little perseverance with this will save the physician from trying the innumerable formulae which are published for the specific cure of sycosis, many of which are, no doubt valuable but all of which are useless unless patiently applied for considerable periods.

Crocker recommends shaving using oil instead of soap, after which a 2 or 3 per cent Ointment of Iodoform, Loretin, or Euphorben should be rubbed in. In chronic cases he uses a 1 or 2 per cent Oleate of Mercury Ointment, and in very obstinate cases he applies Liquor Potassæ for half a minute, followed by Boracic Ointment.

Unna, in severe cases, applies a Carbolic-Mercurial or a Resorcin-plaster muslin to be worn constantly, or when night-treatment only can be carried out, he applies all night a Zinc-Sulphur salve muslin, epilating every morning, and touching the suppurating follicles individually with a 5 per cent. Resorcin Spirit, Corrosive Sublimate, or Carbolic Acid.

Rosenthal claims that the following ointment acts as a specific in the great majority of cases—R. Acid Tannici, ʒss; Sulphur, Lactatis, ʒij; Zinci Oxidi, ʒivss; Pulv. Amyli, ʒivss; Vaselin, ʒss, misce. Fiat Unguentum.

The following modification of this is also recommended:—Tannic Acid, 23 grains; Lactate of Sulphur, 48 grains; Vaseline, 1 oz. Excellent results may be obtained by Corrosive Sublimate Ointment of the strength of 1 grain to 1 oz. Lanoiline.

Any antiparasitic agent applied in dilute solution will effect a cure. Thus the B.P. Ointments of Creosote, Eucalyptus, Borax,

Acid, Salicylic Acid, Carbolic Acid, Chrysarobin, Iodide of Sulphur, Tar, Sulphur, Mercury, Ammoniated Mercury, Calomel Nitrate and Oxide of Mercury, or ointments containing Ichthamm (10 per cent.), Oleate of Mercury (5 per cent.), Resorcin (20 per cent.), Pyrogallie Acid (5 per cent.) may be employed.

If, during the use of these agents, irritations arise, the ointment should be stopped immediately, and plain Zinc Ointment or the Linimentum Calcis, be applied in its stead.

Many authorities insist upon the necessity of constitutional remedies, as Cod Liver Oil, Iron, Quinine, and tonics, and the correction of any departure from the standard of health and sometimes Sulphide of Calcium ($\frac{1}{16}$ gr.) is useful.

In the treatment of tinea sycosis the remedies applicable to Ringworm of the Scalp are indicated. (See under Tinea.) Here, as in the common form of the disease, nothing can be done till, by fomentations and starch poultices, all crusts are removed and irritation subdued. The next step will be clipping of the hairs, and epilation of those evidently diseased or suspected.

The further treatment will consist in the steady and patient application of antiparasitic remedies as mentioned upon the previous page. These must, however, be used in more concentrated form, and Lard or Almond Oil can be applied occasionally to subdue the irritation which they generally produce.

Chrysarobin is unquestionably the most reliable, but owing to the irritation of the face, and the discolouration following its use it can be of little service in this affection. Creosote Ointment is an excellent application. The student will almost despair of making a beginning in the treatment of this affection if he ponders at the hosts of formulæ given in the text-books or scattered through the journals, most of which are vaunted as specifics. Success in the practical treatment of this and other allied affections will consist in the physician making himself thoroughly acquainted with the effects of a few good remedies upon the different kinds of skins. By degrees he soon comes to know the strength of the application suitable in each case. A weak Ointment of Iodide of Sulphur is one of the most certain agents we possess, but it is generally worse than useless owing to the careless way in which it is prepared by the chemist. It should not be used for several days after it has been made up. 15 or 20 grains to the ounce will be strong enough for sycosis.

Citrine Ointment (B.P.) stains the skin less than the Iodide of Sulphur. The Oleate of Mercury (5 per cent.) is a workable and efficient destroyer of the germs which cause the disease.

Greasy preparations are better than watery or spirituous solutions, as these latter will not find their way down into the deep parts of the hair follicles where the parasite burrows, and for this reason the ointments should be applied with friction after epilation.

For the other various agents which may be used in this affection see under Tinea.

SYMBLEPHARON.

Or adhesion of the eyelid to the eyeball, exists in so many degrees and in so many forms as to prevent any definite line of operation being applicable as a routine treatment. In minor degrees the condition can be easily dealt with by severing the adhesion or band by scissors. In severer forms, where the adhesive surfaces cover a large extent of the lid, they must be carefully dissected from each other and a transplantation of a small piece of mucous membrane from the lips or labia effected. The conjunctiva of the rabbit has been grafted successfully. Subsequent adhesion of the dissected surfaces may sometimes be prevented by turning the conjunctival flap upon itself and retaining it in this position by sutures.

SYNCOPE.

Though this is but a symptom of some more serious condition requiring active treatment, the first thing to be done is to attend to the symptom without delay. The patient must be placed in the horizontal position, with his head low—a little lower than the level of his body. All constrictions about his neck should be removed without delay, and a current of pure cold air should be allowed to blow over him when possible. If swallowing is for the time impossible a dash of cold water in the face is a powerful reflex stimulant to the heart, and may be safely resorted to. Ammonia, Smelling Salts, or Strong Acetic Acid to the nostrils, with flapping the hands by a wet cloth, may be tried. Where the attack withstands this, and the patient is still unable to swallow, Ether or Ammonia (Sal Volatile, 1 part; water, 5) may be injected hypodermically, or Whiskey and water, Brandy, Wine, or any available stimulant may be injected into the rectum.

As soon as the power of swallowing returns stimulants may be given by the mouth.

In desperate cases Ammonia, or Ether, or Strychnine, may be injected directly into a vein, and Electricity—the interrupted current—applied to the phrenic nerve or heart. Nitrite of Amyl inhalation may be tried. Where hæmorrhage has been the cause of the fainting, sometimes success may follow the rapid elevation of the lower extremities and the application of a rubber bandage to drive the blood which is contained in them towards the heart. Where these measures fail transfusion may be resorted to without delay. Artificial respiration, frictions, electric shocks through the arms, and the application of hot sinapisms may be tried whilst the more serious operation of transfusion or intravenous injection of warm, weak Saline Solution is being proceeded with. (See under Collapse, page 156.) The Laborde or Krong-Mass methods, described under Poisoning by Chloroform, should always be tried.

SYNOVITIS.

Under Joint Diseases and under Hip and Knee-Joint Diseases the treatment of the chronic forms of this affection is detailed,

when the diseased action has eventuated in pulpy degeneration or in more or less disorganisation of the joint.

In acute synovitis absolute rest must be secured for the inflamed joint. This may be done in various ways, as by the use of splints, sand bags, &c., and the joint should be fixed in the most useful position should ankylosis unfortunately follow—e.g. the elbow should be placed beyond a right angle, the knee fully extended. Such appliances, however, are not to interfere with the application of the remedies about to be mentioned.

Cold applications, either in the form of evaporating lotions or what is much better, ice applied freely round the joint are the most successful of all treatments. Leeching may be resorted to when the pain and high tension do not rapidly yield to ice being applied round the joint. Upon an inflamed knee-joint a dozen or more leeches may be placed, and not only are the local symptoms sometimes the constitutional symptoms are rapidly relieved thereby. If grateful to the patient, hot fomentations may follow the local blood letting.

Free Saline purgation by Sulphate of Magnesia, followed by a diaphoretic containing small doses ($\frac{1}{4}$ grain) of Tartar Emetic at short intervals, is the best constitutional treatment in sthenic and traumatic cases occurring in the robust.

The following mixture may be administered:—

R. *Magnesi Sulphatis* ʒj
Antimoni Tartarati gr ij.
Tincture Aconiti ℥xxxij.
Syrupi Auranti ʒj
Aque Menthe Piperite ad ʒxvj *mixe*

Fiat mistura. Capiat cochlearia duo magna secundis horis.

In those instances where a distinct rheumatic element is present large doses of Salicylate of Soda should be given, and where good figures in the caustation *Conchium* may be safely prescribed with a padding of absorbent wool round the joint, which should then be enveloped in oiled silk.

Opium internally must be given with caution, but when severe pain and high constitutional disturbance are present it cannot be withheld. 15 grs. of Dover's Powder, with 2 grs. James's Powder may be given every six or eight hours. In synovitis in syphilitic patients a few full doses of Blue Pill followed by a smart Saline purge, may be used before putting the patient upon large doses of the Iodide of Potassium.

Where a large quantity of fluid has been poured out into the joint, and there is danger of disintegration occurring from the very high tension, no harm can come from aspiration, followed by rest.

As soon as the acute symptoms have subsided prolonged rest may do harm, and if the joint has passed into the chronic stage a reversal of the treatment may be the first and only line of practice followed by relief. If much fluid remain in the joint after the subsidence of the pain and local heat, elastic pressure by layers of cotton wool, beneath a calico bandage firmly applied, or by a perforated rubber bandage will be found very effective, and in addition counter-irritants are to be employed. Small blisters may be applied in three or four places over a large joint like the knee, or the actual cautery may be lightly pressed against the skin in a few places. These are also the most important agents to use in the treatment of *sub-acute* or *chronic* synovitis. Combined with them massage and friction with stimulating liniments, or painting of the joint with strong Iodine, may be tried.

When the fluid resists these measures it may be drawn off by the aspirator and a soft india-rubber bandage applied for some days. Indeed, it is sometimes wonderful to observe the rapid effect of a rubber bandage over a distended knee-joint when the aspirator has not been employed. Some cases of hydrops articuli yield to this. In other cases strapping by adhesive plaster spread upon some strong fabric serves the same purpose, provided the plaster be removed and reapplied at short intervals as the swelling diminishes. Scott's dressing or a mild Mercurial preparation spread upon lint may be applied to the joint, under the strapping. By these means much fluid and even thickening of the synovial membrane may be got rid of, by the assistance of passive motion and gentle exercise of the joint and the internal administration of Iodide of Potassium.

The French method of injecting the joint with one or two drachms of Tincture of Iodine exactly as for the radical cure of hydrocele is applicable in those passive cases of chronic synovitis or hydrops articuli, and gives splendid results sometimes. A few ounces of fluid are removed, the iodine diluted with two parts of water is injected and allowed to remain for 3 or 4 minutes, when all the fluid is allowed to flow out. The acute synovitis which results is treated by rest and cold.

When the synovitis is due to the presence of a loose cartilage in the joint, attempts may be made to fix the body in some position in which it will not cause irritation, failing this it must be removed.

When suppuration occurs in the joint there need be no time lost in the trying of these remedies. The only thing open to the surgeon in such cases is to make at least two free incisions into the joint in the most dependent aspect, wash it out thoroughly by a stream of warm antiseptic solution and insert a drainage tube under a liberal supply of antiseptic dressing. Continuous irrigation of such joints has given satisfactory results in many instances. The limb should be placed in the most desirable position for

an anchylosis, though the hope of a movable joint is not to be altogether abandoned. In highly septic cases amputation may offer the only hope of saving life.

Excision, and the various operative and constitutional measures applicable to very chronic cases, which have resisted all the above plans of treatment and gone on into pulpy degeneration, are described under Joint Disease.

SYPHILIS.

The question of treating the local sore or chancre is a simple one. By the time that induration is established all authorities are satisfied that destruction by caustics or excision by the knife is useless as a means of aborting the disease.

When a sore is seen at an earlier stage, before induration appears, the question is different. Hutchinson still insists that if the patient be seen at any time within a fortnight after contagion with a non-indurated sore it should be completely destroyed. The shorter the period, the greater the hope of success, and the excision of the sore by means of the galvano-cautery is the best practice. It is, however, highly improbable that the secondary symptoms can be prevented or modified by excision, even when carried out at the earliest stage.

After its destruction, or in those cases too far advanced for cauterisation, a host of remedies may be employed with the view of assisting the healing process. Perhaps the best routine agent for use is the Black Wash, applied on lint and changed frequently. It is no doubt inferior to Iodoform, which answers every indication perfectly, but owing to its easily recognised and penetrating odour this latter must often be laid aside. Where the sore is inside a long prepice this objection hardly maintains, as there is little chance of its volatilisation or the escape of its odour, but, as a rule, Iodoform has far more striking effect upon the soft sore.

Where the sore refuses to heal under this treatment it may be occasionally touched lightly with the Liq. Hydrarg. Permut. or if any marked tendency to spread is noticeable the fuming Nitric Acid should be at once freely resorted to. Phagedæna must be met by the agents detailed under Gangrene (Hospital). In every case of chancre the most rigid attention to absolute cleanliness is necessary.

The vast majority of cases heal up under black wash. Where there is much moisture about the sore Calomel is an excellent remedy when freely dusted over it. Where the sores are placed upon the outside of the penis much trouble may be saved by Bloxam's simple plan of applying a small piece of the B.P. Emplastrum Hydrargyri spread upon wash leather. In the case of female patients, cleanliness can only be obtained by the constant use of the sitz warm bath twice a day.

The constitutional treatment at this stage of the disease will embrace everything calculated to improve the general health—i

light nutritious diet, abundance of fresh air, moderate amount of work and a fair proportion of exercise, and a total cessation from all indulgence in alcohol in every shape and form. Tobacco may be permitted, but only in strict moderation, and over feeding and all excesses must be discountenanced. It is hardly necessary to state that sexual indulgence must be strictly forbidden.

Mercury is the only reliable drug in syphilis. Where failure follows, it is owing to some error in its administration.

Many points still remain to be proven as to the time, methods of administration, &c., but these are being gradually set at rest by the researches and observations of reliable authorities all over the world. The first real step in advance was made when it was demonstrated that in order to cure syphilis by mercury, salivation is unnecessary. This important fact is the key-note to success in the treatment of the disease, and its clear recognition means more than what lies upon the surface. It is not merely because salivation in the old sense of the term is now known to be injurious to the patient, but because of what follows in connection with the action of the drug. When mercury was given in heroic doses to produce salivation as rapidly as possible, the administration of the drug had to be suspended for a very considerable period, and with many physicians was never again resumed in the case; we know now that the best results are only to be obtained by *small doses of the remedy administered uninterruptedly over long periods*. Later on, the different methods, hypodermic, epidermic, &c., will be detailed.

The first great question to be settled is—Should the drug be administered in the primary stage of the disease? Some affirm that it is useless or even injurious. Hutchinson says—"I believe that it is quite possible by the early and continuous use of Mercury to suppress the secondary stage—in other words, to make it abortive. In exceedingly few cases where it has been possible to use mercury without interruption in this way have I known a well characterised secondary eruption or a typical sore throat to occur. In cases where diarrhoea or sudden pyalism has caused the course to be interrupted the success has been less complete; but where the patient is careful and can bear the drug I may repeat that I believe that it is easily possible to prevent secondary symptoms." At a later date he states "that if treatment be faithfully carried out, syphilis may be wholly suppressed, and the patient may never know anything about his malady beyond its primary symptoms. In many cases he may come to doubt the diagnosis on account of the completeness of his cure." Of the truth of this statement the writer is perfectly satisfied by clinical observation, and he accepts the principles of the abortive plan without any reservation as one of the most certain and brilliant advances in therapeutics.

As soon, then, as a patient presents himself with an indurated chancre, he should be placed under small doses of mercury, as 5 grs. Plummer's Pill, morning and evening, 1 gr. Grey Powder, in

pill, four or five times a day, or 1 gr. Blue Pill, or $\frac{1}{10}$ gr. Perchloride thrice daily.

The following combination has many advantages. —

R. *Hydrargyri Cum Creta* gr. i.
 Quinina Sulphatis gr. i.
 Pulv. Opii gr. $\frac{1}{2}$.
 Extracti Quassia q. s. *misce*

Fiat pilula. Mitte c. Sumat unam quater in die post cibos.

In a fortnight or three weeks the chancre is markedly changed for the better, and the induration is greatly reduced and rapidly disappears as the system gets under the influence of the antidote. The treatment should be steadily persisted in for 6 or 9 months, the gums being watched closely, and the dose diminished upon any marked sponginess or pyalism. In Aix, where the closest attention is given to every detail that facilitates the admission of the largest amount of the drug into the system without affecting the gums great care is exercised by the use of tooth powders and astringent mouth washes to keep the gums in a perfectly healthy condition.

The following is used extensively at Aix-la-Chapelle —

R. *Liq. Alumin Acet. (P.G.)* ℥i.
 Aqua Flor. Auranti ad ℥viij. *misce.*

Fiat lotio pro ore, saepe ulenda.

The writer has seen many failures in the treatment of syphilis within the last 25 years, but he has been generally able to trace these to the nervousness of the physician, who was afraid to continue the drug for a sufficiently long period in sufficient doses, or to the carelessness of the patient, who ceased to take it. Seldom, if ever, has he chanced to see injury done by overdoses, unless in the hands of quacks or irresponsible persons. He is, therefore, led to conclude that much greater injury is done by withholding the drug than by giving it too generously. When giving mercurials for this long period he often found himself anxious lest the patient might be permanently weakened by the drug, but he has never witnessed such a result.

He adopts in these cases a rule of his own, which he ventures to hope will become established by the testimony of other observers who will try it. As long as the patient continues to gain in weight, or as long as he steadily keeps to his normal standard of weight there is little danger to be feared from the action of the drug upon the system. Accurate weighings should be accomplished once a week or once in a fortnight in the physician's study after the patient has been taking the drug for

several months. (Since the above was written many years ago, the importance of the body weight as a test of the dosage is recognised by most observers, and a further advance has been made by improved methods of examination of the blood.) Under this abortive treatment the rash may not appear at all, or if it appears, it is so much modified as not to be easily recognisable. The same may be said of the sore throat and other phenomena. It is, therefore, advisable, if not imperative, that mercury should be given as soon as an indurated chancre comes under notice, without waiting for the appearance of the rash or sore throat. Should mercury be given before induration appears in the sore? In other words given a sore, which may not be syphilitic, are we justified in waiting for changes to take place in it to settle our diagnosis before exhibiting mercury. This question should be easily answered.

Hutchinson thinks that it is possible to cause abortion of the primary stage itself. Whether this is correct or not need not deter the physician from beginning small doses of mercury when he considers that such treatment cannot possibly do the patient any harm.

The writer adopts the practice of beginning mercurials in every case of sore whose history warrants a fair suspicion of its being syphilitic, but he always gives a small dose, one that in ordinary cases would not be likely to prevent induration of the sore taking place. If full mercurial treatment be commenced under such circumstances, it is more than possible that induration in the chancre might never become marked, and the physician, say at the end of a month or six weeks, would be uncertain, or in absolute ignorance of whether he was treating syphilis or not. Under such circumstances he would not be justified in going on with a nine months' course. If syphilitic, however, he probably would find that the secondary symptoms would begin to show themselves soon after the cessation of the mercurial treatment, even at the end of the third or fourth month. By beginning in these doubtful chancres with a very small dose say one Plummer's Pill every night, and watching closely for induration, upon the first proof of which the dose is to be doubled or trebled, the best thing will be done for the patient. By giving the small doses of mercury before the nature of the affection is declared, the physician will have the satisfaction of feeling that he has the disease well in hand, and upon the appearance of induration he has but to tighten the reins.

Grey Powder, 1 grain, four times a day is, perhaps, the most frequently prescribed dose in this country. The Green Iodide of Mercury, formerly a very favoured preparation, is now less frequently employed: it certainly possesses no advantage over the perchloride, Iodate, Calomel, or grey powder.

This continuous treatment should be kept up for 6 months, the dosage being from time to time diminished, but if possible not suspended, as symptoms demand. Then a two or three months'

rest may be given, after which a mild mercurial and iodide course every six weeks, followed by another rest and a final 3 months course of iodides, making in all about 24 months. The entire period may be passed without the patient taking to bed or giving up business, and ordinary exposure to variations of weather if met by ordinary precautions, are harmless, and need not interfere with the treatment.

Many authorities believe that the system soon becomes accustomed to the *continuous* use of the drug, and they recommend its suspension for weeks or months, after which it is to be resumed in full doses. This is known as the *interrupted* method of treatment. The writer does not hesitate to advise the continuous plan, chiefly because he is satisfied that relapses and tertiary manifestations are less frequent under it.

The method of inunction is much in vogue as a routine treatment on the Continent, especially at Aix, where the usual dose is about 75 grains of the German Pharmacopœia Ointment (1 in 3) rubbed in once a day for 20 minutes over the sides of the chest and abdomen and inner aspects of the arms and thighs. These doses would appear to be better borne there than at home. Oleate of Mercury or the Calomel Bath may be substituted. Where the Ointment is employed, it must be rubbed into different parts of the body in succession, otherwise local irritation may supervene. Where the patient is compelled to remain at his business, inunction is not easily carried out, but where he can devote his full time to the cure of his disease, as is done at Aix, this method is preferable to all others. Where a rapid effect is desired, as in cases of neglected syphilis, or where pressing brain symptoms arise in the later forms of the disease, this method may be imperative, or wherever we wish to obtain the full physiological action of the drug. In such cases at Aix 120 grains are rubbed in twice daily.

The Aix method can be well carried out in Harrogate and Bath, but it must be regretted that up to the present the perfect arrangements and skilled nurses, which can be had upon the Continent, are not ordinarily available in England.

Welanders's method of causing the patient to wear a mercurial shirt is based upon the erroneous idea that inunction by the ointment the drug finds its way into the blood by inhalation of the evaporated metal. It may, however, prove a handy plan of treating the disease in some cases where inunction and secretory are both necessary.

Mercuriol, which is an amalgam of magnesium and aluminium, is a very suitable drug for Welanders's method as it decomposes under the heat of the body, leaving the mercurial vapour free for inhalation; it may be worn as a sachet. This drug is not to be confounded with Mercuriol, which is a compound of mercury with the nucleonic acid of yeast; it is a brown soluble powder, and is given in syphilis, and used as an injection, 2 per cent., in gonorrhœa.

The intra-muscular or hypodermic injection of the drug in various forms has been very extensively used on the Continent; the writer has very limited experience of it. Bloxam, who has injected many thousands of times, justly remarks that it is only by this method that the physician can form any correct idea of the quantity of mercury absorbed into the system. Formerly he used the intra-muscular injection of a Solution of Corrosive Sublimate (8 grs. to 1 oz. water), and the dose was 20 minims once a week into the gluteal region. 1,924 injections were made. Only one case gave any trouble, and this was where the solution was injected by mistake into the subcutaneous tissue.

Though these results were highly satisfactory, he found that the pain and smarting often lasted two or three days, and he has obtained better results by using a Solution of Sal Alembroth—a double Chloride of Mercury and Ammonium. The following is his formula:—

R. *Hydrarg. Perchloridi* gr. xxxij.
 Ammonii Chloridi Pur. gr. xvj.
 Aquæ Destillatæ ad ℥ij. *misce.*

Fiat solutio.

The dose of the above is 10 minims—equal to one-third of a grain of Mercuric Chloride. It produces comparatively slight pain, and the least trace of induration. After two injections equalling two-thirds of a grain of Mercuric Chloride, the physiological action of the drug was produced and could be maintained by an injection once a week, whilst the symptoms of the disease, both local and constitutional, underwent most rapid and favourable change.

After decided mercurialism has been established, the injections are to be made every fortnight only, and when the glandular and throat symptoms have disappeared, once a month. This is kept up from 15 to 23 months, and the average total quantity of mercury used in Bloxam's cases only amounted to about 8 grains of the perchloride during the entire treatment.

Lewin gives his verdict strongly in favour of the injection of 6 per cent. Sublimate Solution in distilled water, his dose being 30 minims of the liquid daily. His experience embraces 80,000 cases.

Vollert recommends the Succinimide of Mercury as the best form for injection. His formula is:—

R. *Hydrarg. Succinimidi* gr. iij.
 Cocainæ Hydrochloridi gr. ij.
 Aquæ Destillatæ ℥v. *misce.*

Of this clear solution 20 minims should be injected daily and it is claimed for it to be the least irritating of all the mercury salts.

There are still great differences of opinion about the injection of the insoluble salts of Mercury, and reports are most contradictory concerning the untoward events which follow. *Lang* affirmed that he had neither abscesses nor other accident in 400 injections of 10 centigrammes ($\frac{1}{10}$ grs.) of the Yellow Oxide in grains of Vaseline Oil. The Mercury is detected in the urine in less than twelve hours after the injections, which should be made deeply into the buttock. Other observers confirm these statements, whilst many report that abscesses and pain have been the rule.

Calomel, Oxybenzoate of Mercury, and other salts, are used in the same way. "Grey Oil" is a favourite form of injection, having been used first by *Lang*. It consists of a weak lanolin ointment of mercury rubbed up with olive oil, and contains about 30 per cent. mercury. The dose is '2 or '3 c.cm. injected into the back.

Leloir uses a third of a syringeful every nine days of Grey Oil, made by mixing 80 parts Oil of Vaseline, 10 of ether, 2 Timetre of Benzoin, and 40 of pure Mercury. Salicylate of Mercury rubbed up with Vaseline or Mucilage is also highly spoken of.

Recently *Bureau* injects 8 minims of a mixture of Salicylate of Mercury 1, and Oil of Vaseline 7, and it is claimed to be the best method of treating syphilis.

Lambkin urges the advantages of his Grey Oil in the treatment of soldiers in India, where it is of vital importance that the surgeon can see that the drug is really administered; he injects into the gluteal muscles 10 minims once a week of the following: Mercury, 1; Lanoline 2; Carbolic Oil (5 per cent.), 4 parts; platinum-iridium needles are used.

Upon the whole, it cannot be said that the routine administration of Mercury by deep muscular injections has been gaining ground, and several authorities condemn the method without reservation. Others think it may have an application whereunction fails, and in cerebral syphilis where urgency is manifest. In these latter cases there can be no doubt that *intra venous* injections of 5 minims of a 1 per cent. Cyanide of Mercury solution, as practised by *Bacelli*, are perfectly justifiable. The writer concludes from an extensive study of the literature of the injection method that its great drawback is the percentage of relapses, and he concludes that any plan which does not provide for the continuous uninterrupted administration of the drug for long periods cannot be satisfactory.

The various complications or local manifestations which appear during the course of the disease, as a rule, steadily disappear as the

curial treatment is pushed, and this is all that is necessary in vast majority of cases in the secondary stage.

The serum treatment of syphilis has been tried in various ways, by infecting horses, goats, sheep, &c. with syphilis, and taking the serum of their blood into syphilitic patients, and also injecting the serum of cured syphilitic patients into patients suffering from secondary symptoms. The results at present published show that the latter method is highly efficacious, but is very unlikely that the plan will ever come into general

use, merely will it be necessary to inaugurate any special treatment for the skin eruptions. When these occur about the face, so as to render it highly desirable to hasten matters, a mild mercurial treatment, as Calomel or White Precipitate, 20 grs. to 1 oz. Lano may be used. Where the skin eruption is very formidable a calomel bath may be resorted to, the patient sitting upon a t-bottomed chair, or with his body in a chamber devised for purpose. As he receives a vapour bath, calomel is sublimed by the heat of the lamp which boils the water, and it is deposited as dust over the surface of his skin, after which he lies down under blankets. The Turkish bath during the mercurial course is believed to hasten the disappearance of the rash.

Mucous patches on the throat and mouth, and about the vulva and anus, though they yield in time to the steady use of the mild mercurial, have their disappearance hastened by a light friction of the Solution of the Permanganate of Mercury, and the writer often applied this to the tonsils. Warts upon the tongue may similarly be treated in these cases, as any form of local irritation greatly aggravate matters. Smoking must be strictly forbidden. Where the ulcers are deep a little of the powdered calomel may be blown into them with the insufflator. The surface may be dusted over condylomata, but a mixture of Calomel and Oxide of Zinc answers very well.

Through the mercurial course diarrhoea is to be avoided, and for this reason a small quantity of Dover's Powder or Laudanum may be combined with the mercury when any tendency in this direction is observed. When rapid action is desired the patient should be advised to give himself up to the treatment, and either remain in bed or in a warm room, as free exposure to the air retards the action of the drug, probably by hastening elimination. During the treatment of the secondary stage with mercury it may be necessary to give iodides especially when the temperature is high, when the bone pains are marked, or where there is evidence that the mucous membranes are extensively involved. Iodides may be used in the later months of treatment with great benefit, and in the intervals during the suspension of the mercurial. They are sometimes used in the early stages too freely to the detriment of the patient. Cod Liver Oil often comes in well in

the late stages in thin subjects. The following may often be met with advantage at this stage. —

R. *Tinctura Podophylli* ℥iv.
 Tinctura Quininae ℥iiss.
 Tinctura Chiratae ℥iiss. misce.

Fiat mistura. Capiat cochlcare min. ter in die ante cibum paululo vin. serici.

There is no doubt, as pointed out by Murray that Quinine is of great value in the late secondary stage, and it can be advantageously combined in full doses with large doses of iodide. He gives 5 grs. of quinine with 15 grs. iodide three times a day.

Chlorate of Potash is a drug of much use for its local action upon the mucous membrane of the mouth and throat, and when pyhalism occurs it may be resorted to at once as a mouth wash and gargle (1 in 40). It has no action in the blood upon the disease, as some have thought. The following may be used —

R. *Potassii Chloratis* ℥iv.
 Glycerini Boracis ℥j
 Aqua Rosa ℥xv. misce.

Fiat Gargarisma. Signa—"To be used as a gargle frequently and one table-spoonful to be swallowed after meals, three times a day."

In single subjects contemplating marriage the administration of the drug in small doses should be continued up till after the event has been consummated when this occurs inside two years. Marriage should always be put off for at least two years from the period of contracting the disease. Where this law cannot be carried out the writer makes it a rule to insist upon the absolute necessity for a mild Mercurial course being followed by the female as soon as conception has been known to occur. He considers this latter point a matter of the gravest importance, and with a little tact it can nearly always be managed without the risk of exciting suspicions which might lead to serious unhappiness.

So much for the treatment of the secondary and intermediate stages. The tertiary manifestations of the disease will require another drug for their destruction. Iodide of Sodium or Potassium has been already referred to; seldom is it indicated in the secondary period, but occasionally it has been found necessary to give it where the early periostitis of bones causes much pain and where the ulceration of the throat does not readily yield to mercury, and it certainly has a marked influence over the high

temperature often met with during the secondary stage. Nevertheless, it is regarded as a drug to be reserved for the treatment of the later or tertiary stage.

Continuous doses of mercury, if administered for a long time, very materially diminish the chance of tertiary symptoms. This view is at least held by several, and it is accepted by the writer, notwithstanding Groen's statistics of the disease in Norway where mercury is seldom used. It has its influence upon the treatment of the sequelæ in this way—that, given marked tertiary symptoms in a patient who has had little mercury administered to him in his secondary period, this drug will be found to act very rapidly in removing them.

Iodide of potassium is given for every tertiary symptom. Under its use large gummatous tumours melt away, and nodes, which had withstood all other agents, disappear as if by magic. Many affirm that its effects are transitory, and that relapses always occur, and that in no sense is it curative. This is quite true, if its use be not continued long after the apparent removal of the local affection; but there is sufficient clinical evidence to show that in many cases without the use of any other remedy the iodide has effected a removal which had become permanent. In dealing with tertiary manifestations, and the effect of iodides upon them one can be quite satisfied that when they disappear it is not spontaneously, but by the result of the action of the drug as these affections, if let alone, seldom show any tendency whatever to resolve.

Notwithstanding these considerations, it will be a safe rule for the physician to make for his own practice, that in no case should the action of the iodide be depended upon unless followed immediately before or after, or used in conjunction with, mercury in some form or other.

For the group of symptoms known as "intermediate" the best treatment will be a combination of the iodide with the usual mercurial dose. Under this plan choroiditis, testicular sarcocèle and various early cerebral affections disappear, and the specific action of the iodide seems to increase as the affections become more and more separated from the primary stages, as pointed out by Hutchinson.

Given a case of read and unmistakeable tertiary nature, the question will arise—Should the iodide be commenced at once without waiting for the action of mercury? This will depend upon various points in the history of the treatment of the case, and also upon the exact locality and gravity of the lesion. Where mercurial treatment had not been patiently carried out in the secondary stage, the best results are to be expected from it. It is in these cases that the Aix method, or the Vaseline Oil and Yellow Oxide of Mercury injections do so well, even after the failure of the drug by the mouth.

If, then, the tertiary lesion resists mercury, or if it appears, say,

in the form of a cerebral tumour, the iodide should be commenced at once. As a rule, it is useless to begin with small doses. The writer has never observed that the best effects may be noticed from small doses. Hutchinson states that he has known patients cured in the most definite manner by doses of less than a single grain, and he also remarks that the most severe untoward effects have followed very small doses.

The writer's plan is to begin with 5 grains three times a day and gradually increase till 20 grains are taken in each dose. It is a very remarkable fact, about which there cannot be a shadow of doubt, that the irritation and troubles following small doses, say 2 grains of the iodide, speedily disappear upon doubling or trebling the dose. Idiosyncrasy is not affected in this manner.

It is not an uncommon experience to find a patient who has taken far doses of the iodide for many months for nodes with out the least result. If the dose be suddenly increased, say to 20 or 30 grains, the nodes begin to disappear as if by magic.

The American system of giving half-ounce doses is not to be recommended. One drachm in the day meets the requirements of the great majority of cases, and, as just mentioned, it is remarkable how soon all coryza and other unpleasant symptoms disappear when full doses are given. Wood lays down the law that where such doses as these are tolerated, it amounts to a proof that the disease under treatment is syphilitic, so satisfied is he of the great toleration of the drug which this disease establishes. This law is at variance with all clinical experience; one sees very large doses constantly tolerated even for long periods in the treatment of many diseases as psoriasis, diabetes, &c., where there is no reason to suspect that the patient had ever contracted syphilis.

Recent experience shows that in treating tertiary affections of the brain and cord, and in chronic affections of the blood vessels following syphilis, the action of the iodide is considerably augmented by combining with it a nitrite. Nitroglycerin and Tetranitrate of Erythrol, being slower in their action, are to be preferred.

Thyroid Extract has been successfully given in cachectic cases in the tertiary stage, and it may prove a valuable adjunct, but it cannot be regarded as in any sense antidotal.

One very important therapeutic law may be formulated about which there can be little question—*i.e.*, that in tertiary syphilis the local action of mercury and iodides is incomparably greater than in the secondary lesions, and just in proportion to the remoteness of the tertiary affection from the secondary, so does the importance of local treatment increase. This is demonstrated in cases of rupia, serpiginous ulcerations, lupoid growths and ozæna, where iodotomies or mercurial applications act speedily after failure of internal treatment with both iodides and mercury.

The choice of local applications will lie, in the majority of cases, between the Acid Nitrate of Mercury Solution and Exsiccans

applied in powder freely or as a strong ointment. The internal administration of iodides and mercury must be persevered with at the same time, but oftener mercury is found to disagree with tertiary patients than with those suffering from the primary or secondary stages of the disease. It is in such cases that the Calomel bath, injections, orunction do so well when the drug by the mouth appears to fail.

Various forms for administering mercury and iodine together in tertiary syphilis are used. The Biniodide of Mercury in the form of pills, each containing $\frac{1}{4}$ grain, is very effective.

Donovan's Solution has long maintained its reputation, and the B.P. formula (containing 1 in 100) may be given for long periods in doses of 20 minims. Perhaps the best of all combinations is Corrosive Sublimate, prescribed in Iodide of Potassium Solution. Its great advantage lies in the facility with which the iodide or the mercury can be increased or diminished at pleasure according to the effects required :

R. *Hydrag. Perchloridi* gr. iss.
 Potassii Iodidi ʒiij.
 Aqua Destill. ʒxij. misc.

Fiat mistura. Capiat coek. mag. ter in die ex aqua post cibos.

This mixture may be given for a month at a time, when the mercury may be stopped, the iodide being administered without it. At the end of the second month the mercury can be added, and so on each alternate month. Tannate of Mercury is recommended in tertiary syphilis in doses of 1 grain twice or three times a day, but it has no advantages over other preparations.

Where large doses of the iodide are to be continued for long periods, the Iodide of Sodium should be selected, as it has a less depressing effect. Some authorities advise the use of a combination of the Iodides of Sodium, Potassium, and Ammonium.

Iodalbacid is vaunted by Blum, it is a compound of iodine with a proteid nucleus containing 10 per cent. of iodine and it is claimed for it that it is more suitable than ordinary iodides where a long continuous effect is desired.

Szudek has been employing Iodol in tertiary syphilis with success, and its use may be a distinct gain in a certain class of case where a slower and more continuous effect is required than that of the iodide of soda or potash. Its action is identical with these salts, but it is more slowly eliminated. He gives it in 15 grain doses in powder, enclosed in unleavened bread. It may be applied locally, and though less efficacious than iodoform, it is devoid of its disgusting odour.

When very large doses of the iodides are considered necessary, it is well to stop the administration of mercurials for a time, and it

appears probable that a small proportion of arsenic diminishes the tendency to skin eruptions.

The following combination may be used. —

R. *Sodii Iodidi* *ʒiv.*
 Potassii Iodidi *ʒiiss.*
 Ammonii Iodidi *ʒiiss.*
 Liquoris Fowleri *ʒij*
 Glycerini Purificati *ʒa.*
 Liquor. Sarsæ Co. Com. ad *ʒxxx. m℥ss.*

Fiat mistura. Capiat cochleare magnum post cibos ter in die cum cochleare magno aquæ.

The iodide treatment may require, in some cases, a longer period than the original mercurial course. Some patients may be kept upon it, with occasional breaks, for two years. It must be persisted in till every trace of the local affection has long disappeared.

Gowers lays great stress upon the dangers of iodides when administered for longer periods than a few weeks at a time. The writer has seen large doses administered for one to two years without a break, and no ill effects whatever were observable. It is well, however, to give a rest of 14 days every two or three months when the symptoms are not urgent.

It is hardly necessary to emphasize the necessity for close attention to the state of the general health in tertiary syphilis. Change of air to the sea-side and a long sea voyage may be necessary in tedious cases.

Congenital syphilis must be treated upon the same general principles as in the ordinary acquired variety. Success is likely to crown the efforts of the physician in the most unpromising cases. Failure is too often caused by timidity in pushing mercury. It must be borne in mind that children bear large doses of the drug safely, and the writer elsewhere ("Pharmacy, Materia Medica and Therapeutics," 7th Edition) has pointed out that it is almost impossible to do harm with Grey Powder to infants poisoned by syphilis as long as their tissues are saturated with the syphilitic virus, as this latter acts as a vital antidote to the mercury. When the disease is destroyed by the drug, the child begins to show signs of not tolerating it so well. Salivation is almost impossible and it may be laid down as a safe rule that it may be pushed as long as the child continues to thrive.

For an infant four months old $\frac{1}{2}$ to $\frac{3}{4}$ grain of Grey Powder may be given three times a day for several days. Then the same dose once a day may be continued for many weeks. If the physician have doubts about pushing it further, he should make

careful weighings of the patient, and any steady diminution of weight will be a strong indication that the treatment should be suspended.

The writer is satisfied of the truth of the following statement which he made some years ago:—"Weak, emaciated infants bear larger doses when poisoned with syphilis than they can when afterwards apparently cured and fattened; but if, after a period of neglect, syphilitic symptoms come on markedly, then they bear very large doses again."

The old-fashioned method of smearing weak Mercurial Ointment upon a flannel roller wound round the abdomen is a very good one. The movements of the body rub in the drug as in the ordinary operation ofunction, but the physician has no guide to the amount absorbed. The writer has had excellent results by using a roller saturated with Cod Liver Oil, to which a small quantity of the ointment had been added. Over this a broad binder of mackintosh is applied, and the oil renewed every morning or evening without changing the roller. Marked increase of weight always follows this simple but invaluable plan.

The Mercurial may be suspended from time to time, but should not be discontinued for at least one year.

Cod Liver Oil and Syrup of Iodide of Iron, to which a small quantity of Iodide of Potassium has been added, should be given at various opportunities during the course.

The milk of the child's mother may be given to it with advantage if she be also put upon a mild mercurial course at the same time, and in very mild cases this treatment may possibly be sufficient. It is, of course, out of the question to put the child to the breasts of a healthy wet nurse owing to the danger of infecting her through the nipples. If hand feeding must be adopted, unusual care will have to be taken during the first six or nine months, and beef juice should be given at least once a day. The milk of the ass is said to do well in such cases.

The treatment of the mother during pregnancy is of vital importance, and the writer has never seen a case of death from congenital syphilis where this was skilfully carried out.

Riehl has pointed out why the results of treatment have been so unsatisfactory in those cases where maternal infection and conception have been synchronous. It is in these cases that the greatest danger to the fetus exists. He maintains that to get the best effects of Mercury the drug must be used *locally* as well as by the mouth or unction. He accordingly gives 15 grs. of the G.P. Ungt. Hyd. in the form of pessary in addition.

TALIPES—See under Club Foot (Page 151).

TAPE-WORM.

A very large number of drugs are known to act as poisons to these parasites when administered in the ordinary way to the patient in whose intestines they have taken up their abode. Every year brings out new agents for this purpose but in spite of the great activity in this department of therapeutics, the Liquid Extract of Male Fern still maintains its supremacy as being the most reliable of all vermifuges. By care in its administration, and by a knowledge of the way in which it acts, the physician will very seldom have to resort to any other agent. Its only drawback is its very nauseous taste and its liability to upset the stomach but these objections can be overcome by improved pharmacy.

It is efficacious against the *tænia solium* and *bothriocephalus* but it must be given in larger doses than those usually prescribed. Less than one drachm is generally of no value. Some authorities recommend a dose of 4 drachms, and J. O. de Man publishes a list of 28 cases where the dose was from 2 to 9 drachms, the average dose being about 6 drachms.

This dose would probably be generally fatal if the extract was skilfully prepared from an active rhizome. The male fern is of varying activity, according to the soil and climate in which it has been grown, and the only way to reconcile the doses of Man is to assume that he had an inferior extract. Potain has pointed out that certain parts of Normandy, for example, produce male fern which has no effect. The writer thinks that the various discrepancies regarding dosage may also to a large extent be explained by the difficulty in distinguishing the fronds and rhizomes of *Aspidium Filix-mas*, *Aspidium Filix-femina* and others; the filix-mas exhibits eight fibro-vascular bundles on a transverse section of the petiole base. The identity of the fern should be carefully made out before the extract is prepared, and the physician should be very particular about the pharmacist to whom the dispensing of this drug is entrusted. Of an active extract four drachms has several times caused death. One drachm is, however a fair average safe dose.

Several precautions are necessary in order to make the attack upon a tape-worm a success, and these maintain in the case of all other vermifuges or vermicides. Thus the alimentary canal must be as empty as possible, so as to permit the drug to exercise its undiluted effect upon the parasite. For this reason these drugs should be given after a long fast, or better still, after a brisk saline cathartic. It is also advisable to recommend the patient to maintain the recumbent posture for a few hours, as vertigo and even syncope, may follow the action of a full anthelmintic dose of most of the agents employed in tape-worm disease. Then as many of these agents simply act by killing the worm, a purgative should be given soon after or along with the vermicide. The fragments of the worm must be very closely examined after expulsion. Very often only a large number of the so-called "joints" are passed and

the head is left behind. Failure then, of course, results, as the head goes on growing, and the dose should be repeated in such a case after a day or two of a rest.

There may be more than one worm—an event much more frequent than is usually supposed, and only a very close scrutiny of the detached portions will enable the physician to be sure of this. The writer has seen this condition of matters several times.

Given then a case of *tenia solium*, the physician should give about 4 or 6 drachms of Sulphate of Magnesia in a bottle of lemonade, late at night, or very early in the morning by daybreak. A few hours after purgation a dose of not less than 1 drachm (in strong subjects 90 minims) of the fluid extract of male fern is to be administered. This may be followed in about four hours by a full dose, 6 to 8 drachms of Castor Oil, alone or combined with about a drachm of pure Spirit of Turpentine, but, as a rule, this purgative dose is not required, the male fern, if of good quality, acts generally as a smart cathartic. The worm is speedily expelled dead, and the patient should be warned to gently wash it and look out for its head.

There is, as already mentioned, much difficulty in administering the drug. The following is a good working formula —

R. *Ext. Filicis Liq.* *min.* lxxv.
 Ovi Vitellum *℥*.
 Aquæ Chloroformi *℥*
 Syr. Simp. q. s. ad *℥ij misc.*

Fiat haustus, mane sumendus.

Many advise Turpentine to be added to this draught, and some put in 5 grs. of Calomel, whilst others insist upon combining small quantities of every vermicide with which they are acquainted. This latter practice is to be condemned, and so is the calomel, which is too slow in its action, but the turpentine seems to do good. Manson advises three or four doses of half a drachm each of the male fern at intervals of half an hour, to be given in emulsion or in milk, and to be followed by Calomel, Scammony, or Castor Oil.

Ether and Chloroform are sometimes combined with the male fern with the view of increasing its effect and preventing griping. The simpler the form in which the drug is administered the better.

Now and then a patient presents himself who cannot possibly keep down a draught such as the above. The best thing to do in such a case is to get a known and reliable chemist to send a good sample of the liquid extract to a capsule maker, and have it *freshly* made into capsules, containing 10 or 15 minims in each. 4 to 6 of these swallowed during fasting may glide through the stomach,

and as they rapidly dissolve in the intestine they exercise their lethal action upon the parasite.

The following formula of the London Hospital may be tried -

R. *Ext. Filicis Liq.* ʒj.
 Syr. Zingiberis ʒj.
 Tinct. Quillanæ ʒss.
 Aquæ Destillatæ ad ʒiiss. *misce.*

Fiat haustus.

It is not a bad plan to give a small dose of Laudanum, Brandy, Antipyrine, or other sedative, such as Peppermint, along with the subsequent draught of Castor Oil, to prevent griping and irregular contractions of the bowel, which might tend to break off the worm at the neck. There may be no grounds for such a belief, but such a plan can do no harm.

Duchesne advises the following made into a firm jelly, which can be easily taken by children:—*Ext. Filicis Liq.* ʒj. ; *Hydræ Subchlor.* gr. vj. ; *Sacch. Alb.* ʒii ; *Gelatin* q. s. *ut fiat electuarium.*

This quantity would certainly be too much for a very young child. A boy five or six years old might take the half of it.

Rothe recommends that Chloral Hydrate (believed to be a vermicide by some) should be combined with the male fern in combination with a smart cathartic in the form of a capsule the whole given together, thus avoiding subsequent pain and the administration of a purgative. His formula is—Chloral, 18 grs., Extract of Male Fern, 30 grs.; Croton Oil, 1 or 2 drops. This is a severe dose, though he says it prevents pain and griping, and acts inside three hours.

Whatever the form in which male fern is given it should only be prescribed in two doses at the most, one to be taken the morning following or, perhaps, within four or six hours after the first dose. The plan of ordering several doses in a mixture to be taken continuously after short intervals is apt to lead to severe intestinal inflammation, and may cause death.

The following brief summary of our chief anthelmintic agents may be useful for reference when male fern fails —

Turpentine has long enjoyed the reputation of being a valuable agent in killing tape-worm, but to be of any use it must be given in doses of at least 4 fluid drachms. This quantity often excites strangury and serious symptoms. Moreover, it is most objectionable as to taste and smell, and now it is seldom employed for these reasons. If selected after the failure of male fern, it should always be given with about 1 fluid ounce of Castor Oil after fasting. The parasite is expelled dead; and it also affects the round worm.

Koussou should be given in doses of 4 drachms infused in boiling water, which is swallowed without straining as soon as the infusion is cold. This dose generally not only kills the worm, but causes its expulsion in fragments without any further purgative. Merck has isolated the active principle, Koussin, which may be given in capsules in doses of about 40 grs. Bedall's Koussin may also be given in the same form, and in similar doses. Wafer paper answers all requirements, and these preparations are more certain than the crude drug, which is much valued in Abyssinia.

Kamala acts in the same manner as koussou: 2 drachms kill and generally expel the worm when given (after a long fast) suspended in syrup, mucilage, or gruel. Anderson's Tincture is made by macerating 9 oz. of Kamala in 21 oz. strong Alcohol, the dose of which is a large tea-spoonful. Large doses may purge very severely.

Pomegranate (the bark or rind of the root and stem) is one of the most certain vermicides we possess. Many prefer it to the male fern. It may be administered in the ordinary decoction (4 oz. to 20). Of this 1 to 2 oz. may be swallowed every hour for three doses after fasting.

The drug deteriorates by keeping, but a great advance has been made in its therapeutics by the isolation of the active principle by Tanret, who extracted an alkaloid, which he calls Pelletierine. The Sulphate or Tannate of this alkaloid is the best form for administration. It may be given in 6 grain doses. Its efficacy is said to be increased markedly by a 10 grain dose of Tannin given immediately before it, though Manson denies this, and says that the tannin only acts as a stomachic and prevents vomiting. He also states that the alkaloid should not be administered at all to children under eight or ten years old.

Schröder has demonstrated that the one ten-thousandth part of this substance, when added to the fluid in which a living tape-worm is placed outside the body, causes its death in a few minutes.

It should be given fasting, and followed in from a quarter to half an hour by a smart purgative.

Bepo—the seeds of the common yellow pumpkin are found to be harmless and often efficient, and, upon the whole, in the present state of our knowledge, they are the best agent for children. A table-spoonful of them may be pounded into an electuary, with sugar, and given to a fasting child, a purge following in three or four hours. Wood gives the adult dose as 2 ozs. The greenish resin obtained from the perisperm may be given in 10 to 20 gr. doses.

Embeha Ribes seeds, given in similar dose and form as in the case of the latter drug, is a favourite East Indian remedy.

Areca Nuts are highly vaunted, and they have been long prized in veterinary practice. 1 to 6 drachms have been frequently

given. The proper dose is, perhaps, about 2 drachms given in milk after a long fast, and followed by a very brisk purge. The active principle is a liquid alkaloid resembling pelletterine in which the name *Arecoline* has been given. It has an action resembling Muscarin.

Cocoa Nut has certainly some action, but the milk and the albumin of an entire nut must be taken to produce any effect. It may be given safely to children.

Ether and Chloroform, and, more recently, the Hydrate of Chloral have been used with considerable success in full doses with the view of poisoning the worm, which is then to be expelled by a very strong drastic. The writer, if compelled to use the two drugs, would combine them with a large dose of Castor Oil, and in the same way the chloral might be given with 1 to 2 drops of Croton Oil. Rothe gives chloral and male fern together in the capsular form, as previously mentioned.

Thymol in large doses has been recently recommended and found most efficacious, but it is a drug which must be administered with great caution. 15 grs. in capsules or cachets should be given, and this dose may be repeated in two hours for three times. As solvents of the drug should be administered for several hours after; thus all fats, oils, glycerin, alkalies, turpentine, spirits, &c. must be avoided, and a smart cathartic should follow in six or eight hours if purging does not follow, the physician aiming at prevention of the absorption of the drug from the alimentary canal.

Myrtol, in doses of 2 grains in capsules, has been recommended, and Menthol would, no doubt, also act in the same way.

Naphthaline, the intestinal disinfectant, has been tried successfully for tape-worm. 10 to 20 grains may be given in water after

Papaine in large doses has been recently recommended. 10 grs. may be administered after fasting.

Lactate of Strontium in drachm doses has been recommended.

Balsam of Copalva (4 drachms), Salicylic Acid (45 grs.), have been tried successfully in a few cases.

No mention need be made of the old mechanical remedies intended to dislodge the worm from its moorings by irritating, as powdered tin, iron filings, zinc, charcoal, mucuna, &c. Max. If not all, of the strong drastics occasionally act as vermifuges or wrenching the parasite from its position in the bowel.

TENESMUS.

The treatment of this symptom will depend upon the cause and removal of which must be carried out before relief can be obtained. Till the remedying of the cause is effected, some case may be obtained by local anodynes, as Morphia suppositories, small enemata of Laudanum, 40 minims in 2 oz. starch-water, enemata of Ice water, or injections of large quantities of very warm water. The writer's Unguentum Conu is very valuable in some cases.

When the tenesmus is caused by inflamed or enlarged prostate or fissures a suppository consisting of 10 grs. Ichthyol with the ointment and cacao butter is invaluable.

(See under Proctitis, Hemorrhoids, Anus, Fissure of, &c &c.)

Tenesmus of the bladder will be relieved by the agents mentioned under Bladder Affections, Stone in the Bladder, &c., &c.

TESTICLE, Diseases of—See under Hematocele, Varicocele, Hydrocele, Oancer, Orchitis, &c.

TETANUS.

Owing to the great diversity that exists in the severity of the cases, the exact value of drugs in this disease is open to serious differences of opinion; many believe that the cases which recover would have got well without drugs at all. Anyone who studies the clinical aspects of the disease cannot fail to observe how near to a fatal issue are some of the cases which recover, and how near to recovery seem some of those chronic examples of the disease which end fatally. It is obvious that a very little may turn the scale in either way, and the value of good nursing and certain drugs should be regarded as beyond a doubt.

The patient should be put to bed upon a good mattress, in a dark quiet room to which only the physician, nurses, and one or two of his most intimate friends are allowed access. Cotton wool is placed in his ears to keep out sounds, a thick carpet being spread upon the floor. Renzi insists that the physician should grope his way about the room with a dark lantern. The importance of absolute stillness and protection from cold draughts is doubtless very great, and the patient should only be permitted to speak when absolute necessity dictates. By these precautions, the authority just mentioned claims to have cured 3 out of 4 cases.

Feeding is beyond all doubt of more importance than drug administration, and Humphry states that long ago, after the trial of nearly every known drug praised in the treatment of tetanus, he has concluded that the administration of nourishment is the only hopeful treatment. Liquid nutritious foods are to be poured into the mouth. Stimulants are indicated in full doses in the majority of cases, and where swallowing is impossible or very difficult, rectal feeding by strong, peptonised broths may be resorted to. As this often proves unsatisfactory, Rose's method of giving Chloroform twice a day may be resorted to, and when complete anaesthesia has been obtained, the stomach may be filled through a rubber tube with nutritious liquid food, and Humphry goes so far as to recommend the operation of gastrostomy with the view of facilitating feeding.

Constipation may be left alone, as purgatives do a great deal more harm than good, and cold or warm baths are to be condemned owing to the difficulty in administering them, but diaphoretics

and diuretics are called for to hasten the elimination of the poison.

Excision, thorough and radical, of the tissues around the wound when this is on the trunk and the amputation of limbs which are the site of the wound, should be instantly carried out upon the first symptoms of the disease appearing. It is also essential that all peripheral irritation should be met by soothing or anodyne dressings, and rigid antiseptic precautions should be maintained.

Of drugs there is practically no end, every known sedative having been at some time or other tried, and supposed to have turned the tide against the microbe. They may be used to keep the patient alive till the poison exhausts itself by elimination, and in the very worst cases relief of suffering may be obtained.

Bromide of Potassium in full doses generally somewhat diminishes the spasms, and a few mild chronic cases have been reported as cured under its influence, but it need not be relied upon where the symptoms are severe, unless it be given in combination with the next drug.

Chloral Hydrate has been used in many cases which have recovered, and there are some grounds for believing that it may save life occasionally. It must be pushed till the full physiological effects are observed, 30 grain doses being given every three hours or 15 grains every hour or every second hour till some impression is made upon the symptoms.

In prescribing narcotics in this disease, it must be borne in mind that enormous doses may be given.

Opium by mouth, or Morphia hypodermically may be pushed with less danger than chloral, whose depressing influence upon the heart may make itself felt before drowsiness appears. These drugs should be given in proportion to the spasm and pain, no attention being paid to the amount of the dose. 4 to 6 or even 8 drachms of solid opium have been administered in 24 hours without injury. Some physicians combine chloral and opium. Cannabis Indica may be pushed like opium, it is often given with chloral.

Alcohol in *very large* doses, Tobacco in nauseating doses, Nicotine, and Tartar Emetic may be pushed till sickness comes on. Apomorphine, Lobelia, and other depressants have been tried and in a limited number of cases appear to have done some good. Of the series, Alcohol is the safest; most of them are dangerous.

Chloroform or Ether affords the only relief in very acute cases coming on soon after the wound has been inflicted. In this group of cases anaesthesia may be kept up for many hours at a time, and it may be pushed even when death is evidently approaching, as the only way of relieving suffering.

Calabar Bean has been frequently tried, and it certainly has appeared to do good in some cases.

Curare, after a fair trial, has likewise lost ground, and though now and then cases are reported which seem to show that it has done good, just as often are those set aside by complete failures.

Pilocarpine, $\frac{1}{2}$ gr. hypodermically, has given good results in a few cases, and may be tried when other agents have failed.

Antipyrine and Amfebrin have already received the credit of a few successes, and Cocaine has been recommended upon the result of its action in a few doubtful cases.

Atropine injected into the muscles, or Belladonna and Hyoscyamus, Gelsemium and Conium by the mouth, in doses sufficient to produce toxic symptoms, have been recommended.

Nitrite of Amyl and Nitroglycerin occasionally appear to give some relief according to several reports, and the former drug should be resorted to the moment that a spasm threatens.

Quinine in large doses (1 drachm to 2 drachms) has been several times reported as successful.

Baccelli has reported a series of cases successfully treated by the subcutaneous injection of 1 per cent. solution of Carbolic Acid.

Much interest has been created by the discovery that the serum of animals, rendered immune to tetanus, has the power of neutralising the poison of the disease when injected before, at the same time, or immediately after the virus. Enormous doses of the poison may be given to unprotected animals if the serum be injected immediately afterwards. Animals may be protected by previous dosage of the serum, so as to be uninfluenced by doses many thousands of times greater than the lethal dose. There can hardly be a doubt that tetanus in man would be immediately cured in every case by the Antitoxin were it administered very soon after the injury which introduced the virus, but since tetanic symptoms often do not show themselves for many days after the introduction of the microbes they have time to increase and multiply to such an extent that the serum often fails. Behring, who introduced the treatment, has had several successes. Roux and Vaillard, though failing in five cases out of seven, believe that success would have been constant had the injections been given earlier, and they affirm that the serum affords the only rational treatment for the disease. It is quite harmless and destroys the poison circulating in the blood, or else so neutralises the activity of the poison on the nerve cells that they go on performing their functions as if no toxin were present. They recommend *excision of the wound* in every case, and the daily injection of 100 c.c. of active serum as long as the symptoms last. They are perfectly certain of its powerful preventive influence, and they recommend that it may be used in cases of severe wounds where tetanus may be suspected to follow.

Tizzoni and Cattani recommend the injection of the alcoholic precipitate prepared from the serum, but they calculate that in the presence of the advanced symptoms of the disease it will

require in man a dose of the liquid serum of about 7 ozs. or of the alcoholic precipitate of about 3 drachms.

Attempts have been made to intensify the action of the serum by injecting it into the cranial cavity after trephining, and large doses have even been injected into the frontal lobes of the brain.

Notwithstanding all the reported successes, there is little evidence of the value of injections of the antitetanic serum. Great numbers of cures are recorded in those cases where the period of incubation was prolonged much beyond the average noticed in severe cases, and it must be remembered that these are the class of cases where a spontaneous cure is the most likely to occur, and many reported successes would doubtless have been safe without the serum. Nevertheless, the comparative failure of serumtherapy in tetanus in no wise weakens the solid foundation upon which this new department of therapeutics rests, since it is exactly what we are bound to expect from a study of the pathology of the disease. If the writer himself were seized with the symptoms of the disease soon after the receipt of an injury he would not hesitate to have the measures carried out which he put recently into operation in an acute case (under the care of Dr. Magill) where he amputated the limb under chloroform, and injected all the serum available. There can hardly be a doubt that the serum will save life in those cases referred to in the opening paragraph of this article, and therefore it should *always* be tried, but it is needless to say that it must not be permitted to interfere with feeding or the other recognised plans of treatment.

The serum may be injected—

- (1) Into a vein.
- (2) Into the cellular tissue.
- (3) Into the brain.

Intravenous injection is said by Hammond and others to be more efficient than intra-cellular, as it acts more rapidly. In either case, 30-50 c.c. should be regarded as a minimum dose, and repeated once or twice daily till improvement sets in.

Copley reports three cases, all of which recovered under serum injections.

Roux and Borrel have pointed out that the toxins in this disease become fixed in the central nerve cells, and are not likely to be reached through the blood. They have therefore recommended that the serum should be injected directly into the brain. The operation is carried out as follows.—

A line is drawn from one auditory meatus to the other, a second line is drawn from the centre of this to the outer angle of the orbit; the middle of the second line is the point at which the injection is to be made. At this point the skull is perforated by an ordinary piercer under strict asepsis. Through the opening thus made the needle of the antitoxin syringe is introduced into the frontal lobe, or even into the basal ganglia, and the serum very slowly injected. A solution of the dried serum is employed in

dose being 5-6 c.c. The operation may be repeated on the other side. In addition, subcutaneous injections should be continued for some days.

Carless has tabulated 25 cases treated in this way, with 11 recoveries and 14 deaths. This is probably a favourable estimate. The operation is by no means free from danger, and may give rise to apoplectic symptoms, hence the necessity for injecting the fluid very slowly.

Cobb records a case which recovered from the tetanus, but died from cerebral abscess eight weeks after the last injection.

Tetanus or Trismus Neonatorum may be regarded as the same affection as tetanus in the adult, and must be met by the same remedies. In addition to serumtherapy, which has recently been reported as successful in a few cases, Chloral is the only drug to be depended upon, and the writer has satisfied himself about the great value of it when steadily pushed in the case of infants. One grain may be given by the mouth or by the bowel every hour. The utmost cleanliness in the dressing of the stump of the umbilical cord must be attended to, as this affection is liable to spread amongst new-born infants. Soltman recommends $\frac{1}{2}$ grain of Musk every three hours when hourly doses of Chloral for 24 times have failed. Morphia, Calabar Bean, Curare, and the other potent agents should not be thought of.

Dr. J. McCaw has recently reported a case of infantile tetanus treated solely by the serum with success.

TETANY.

The first element in the treatment of this interesting affection is to find out the cause when this is possible; in a fair proportion of cases this is not very difficult, and the cause is sometimes remediable. Thus when tetany is the result of thyroid removal or disease feeding by tabloids of dried gland gives satisfactory results. Where the symptoms supervene during pregnancy they often cease after delivery, and when they first appear during lactation there is a fair hope that they may be removed by weaning the infant. In some of these cases thyroid feeding has also proved beneficial. When tetany shows itself during rickets, the dietetic measures indicated in this disease may be fairly expected to prove satisfactory, especially when combined with free Phosphorus and Cod Liver Oil.

The most formidable cases are those associated with dilatation of the stomach, especially when this is caused by the cicatrization of a pyloric or duodenal ulcer. Here the spasms are not rarely fatal, and though the attack is often excited by washing out the dilated organ, constant lavage must be resorted to. All the measures detailed upon pages 888 and 314 must be carefully carried out, including gastric and intestinal antiseptics, &c., and above all, judicious feeding. The theory that some poison is generated in the fermenting bag which has to do duty for a stomach is probably

correct, hence washing out or the free administration of emetics is valuable. Where the intestinal canal lower down is affected the administration of intestinal antiseptics like Salol, Carbolic, or Naphthol is called for. The presence of tape and round worms must be met by anthelmintics. Search should be made for a toxic agent upon whose presence the symptoms may be supposed to depend, and where this cannot be found or remedied the rational indication is for such stimulation of the excretory organs—skin, urine, and bowels—as will hasten elimination.

For the relief of the spasms a warm bath (90° F.) is quite valuable, and the cautious administration of Chloroform or Paraldehyde or a hypodermic injection of Pilocarpine ($\frac{1}{4}$ gr.) Haubert employs Massage successfully whilst the patient is fully under the anæsthetic. Nitrite of Amyl may be tried. Ice to the spine or a hot fomentation over the sternum has been advocated by Trousseau. Electricity is of very doubtful value.

Bromides in large doses, as in epilepsy, combined with Chloral in severe cases, and combined with Valerianates in chronic cases afford considerable relief.

Eserine, Belladonna, Asafoetida, Hyoscyne, Cannabis Indica and nearly every known general antispasmodic have been tried in. Gowers advocates Digitalis in the nocturnal form. Protection from cold and all depressing causes as overwork, &c., must be insisted upon.

THORACIC ANEURISM—See Aneurism (Page 46).

THREAD-WORM.

Once these parasites have gained admission to the intestinal canal their ova, which are invisible, get under the finger nail in scratching, and are conveyed to the patient's mouth again so that re-infection is constantly occurring. Absolute cleanliness is therefore, an essential, and children should be made to sleep in garments which render this method of infection impossible. It is also highly probable that as they wander about the anus and vagina they may be communicated from one person to another sleeping in the same bed. Their origin in the human system arises from eating uncooked vegetables and fruits, and from drinking water containing their ova. They chiefly infest the lower end of the great intestine, but Cobbold insists that their presence here is accidental, their real locality being as high up as the cæcum. The males and young embryos are found in the lower part of the small intestine, whilst the impregnated females are found in the cæcum, and descend to the rectum to lay their eggs there, after which they pass out of the body in the faeces.

The symptoms caused by the presence of these pests are generally best speedily relieved by enemata containing a large spoonful of Chloride of Sodium in a tumblerful of water. Lime water, Infusion of Quassia, Solutions of Alum, of Aloes, of Ether

in water), of Eucalyptus Oil, of Tincture of Iron, of weak Carbolic Acid, of Turpentine, of Vinegar, of Tansy, of Olive Oil, of Chloride of Ammonium and many other substances, are very useful, and, in the case of children, are generally successful after a few repetitions of the enema.

A little weak Mercurial Ointment just placed within the sphincter keeps them from migrating at night.

Cobboid attaches most importance to internal remedies, and he advises Iron in tonic doses, with Aloes and Asafoetida occasionally, followed by repeated Saline cathartics, as the Friedrichshall and Hunyadi waters. Others recommend large draughts of Quassia or Gentian in infusion, swallowed fasting, and followed by a Saline. Santonin has been given with success.

The writer has always succeeded with salt and water enemata, administered every second night, and in troublesome cases with the internal administration of a course of Iron and Arsenic, giving an occasional purge of Scammony and Calomel.

Naphthaline has been given by the mouth. A child two years old may get 3 grs., and a child of ten may get 5 or 6 grs. with sugar four times a day for two days between meals.

THROAT, Sore.

The treatment of this affection, which is known under various names as Sore Throat, Ulcerated Sore Throat, Hospital Sore Throat, Follicular Tonsillitis, &c., is simple, and it is identical with the treatment of acute septic inflammations of the pharynx and larynx, because all these conditions depend upon the invasion of this region by pathogenic organisms (streptococci, staphylococci, &c.) The constitutional symptoms, which may be very severe in some cases, demand attention even before local treatment. Of the various drugs none act so satisfactorily as Antipyrine. The backache and headache and high temperature speedily subside under a few to grain doses of this drug. Salol in 15 grain doses and Salicylate of Soda give relief also, but the writer finds nothing so good as the Antipyrine, and he has had the personal experience of many attacks. Where this drug cannot be tolerated (which is seldom), the plan of small doses (2 minims) of Tincture of Aconite every 15 or 30 minutes for 8 or 10 times is very valuable. Veratrum Viride acts in the same way. These drugs may be combined with Mindererus Spirit and Nitrous Ether. Quinine in full doses, 10 grs. immediately, and 5 grs. every hour for two or three times, an emetic dose of Ipecacuanha, Cinnamon, large doses of Guaiacum, a full Saline purge, have all proved efficacious in relieving or cutting short the early symptoms.

A milk diet with strong soups, and, in debilitated subjects, a liberal allowance of Port, Claret, or a weak Milk Punch may be ordered. Abundance of pure air and good ventilation are as essential to the patient as they are to those coming in contact with

him, for the disease is highly infectious, and easily spread through sewer gas and polluted water. Locally, the best gargle is that formulated on page 709.

This may be used as a spray or gargle alternately when diluted with an equal quantity of water. It is the best treatment of children when sprayed over the throat every half hour.

Insufflations of powdered Bicarbonate of Soda every 15 minutes are said to sometimes abort the disease but are exceedingly unpleasant, owing to the painful choking sensation caused by the dry powder.

Cold compresses or iced cloths to the outside of the throat may be employed in the early stages, and hot compresses or poultices later, the selection of each being made upon the report of the sensations of the patient.

Raymond swabs the tonsils with pure Guaiacol.

Painting the tonsils and pharynx with a strong solution of Nitrate of Silver (3i to ʒss) occasionally cuts short the attack, and is reported to give speedy relief. It far more frequently aggravates the suffering and does no manner of good, and as a routine remedy should not be employed in the early stage of the affection. At a later stage it very often does great good, specially if the affection tends to become chronic.

In the early stage the whitish mucous secretion may appear to resemble diphtheritic membrane, and if the physician be in doubt he may apply the mixture which Loeffler found so fatal to the diphtheritic microbe. It consists of Alcohol, 64 parts, ~~Eucal~~ 36 parts, Liq. Ferri Perchlor., 4 parts. Strubing adds to parts of Menthol. This, if applied every four hours to the false membrane in diphtheria for 10 seconds, claims results equal to the serum treatment. Loeffler states that it kills the bacillus in 5 seconds when added to cultures containing it.

When the dysphagia is very severe no remedy gives the relief which may be obtained by a good steaming over boiling water but the various inhalers, when used for this purpose, are worthless. A large basin of boiling or very hot water should be placed at the head beside the patient's head, and a linen sheet thrown loosely over all, so as to make a tent, is the best way to utilise the hot vapour. At a later stage alterative or astringent gargles may be used, and these also can be employed as sprays.

1 oz Chlorate of Potassium in 40 oz. water is a favourite gargle, but it is a mistake to persist too long in its use as it may keep up the irritation. The following may be tried. —

R. *Acidi Borici* ʒj.

Glycerini Boracis ʒss.

Infusi Rosæ ʒiiss misc.

Fiat gargarisma

The great advantage of Carbolic Acid lies in its power of paralysing the palatal muscles, and preventing the painful and useless attempts at swallowing of saliva and mucus, acting also as it does as a local anæsthetic. The lozenges may be slowly sucked in the mouth instead of using the drug as a spray or gargle.

Balls of Nitre, pieces of Guaiacum Resin, compressed tablets of Chlorate of Potash and Cocaine, crystals of Borax, pieces of Ice, and Catechu Lozenges are favourite local remedies when permitted to slowly dissolve in the mouth.

As the acute symptoms pass off the value of astringents in hastening recovery is obvious. The following formula is useful. —

R. *Tinct. Ferri Perchlor.* ʒiij.
Glycerin Aluminis ʒiv.
Aque Destillatæ ad ʒx. *misce.*

Fiat gargarisma.

This is indicated where there is much redness of the entire mucous membrane—a condition spoken of as Erythematous Tonsillitis, or when very acute or formidable as Phlegmonous Tonsillitis. In both these conditions the Tincture of Iron should be given internally in full doses (30 to 60 minims) at the same time and combined with this treatment large doses of stimulants are clearly indicated.

A good astringent gargle may be made by mixing 1 oz. of the B.P. Glycerin of Alum with 9 ozs. Rose Water, or Tannic Acid, 1 drachm in 10 ozs. Infusion of Roses.

At a later stage the throat may be swabbed out with the official glycerins of the two last mentioned drugs. Capsicum is only available in the very last stages.

Where there is fetor, weak solutions of Chlorine, Permanganate of Potassium, Creolin, Iodine, Sulphurous Acid, Chloride of Zinc, or very dilute Perchloride of Mercury are indicated.

As convalescence is approached, tonics with the Mineral Acids, Iron, Quinine, and Bitters may be indicated.

Acute Tonsillitis is to be treated upon exactly the same lines as the Follicular Tonsillitis or sore throat—many cases of either disease running into the other or becoming undistinguishable.

Antipyrine or Salicylates internally, hot poultices externally, with steaming over boiling water and sprays of Carbolic Acid, to which a little Glycerin of Borax and Cocaine have been added, are the main drugs to be relied upon. (See formula on page 709.)

Abscesses in the tonsil should be opened as soon as their presence is ascertained. This may be accomplished by taking a sharp pointed bistoury, and protecting its blade with a layer of strapping to within $\frac{1}{2}$ or $\frac{3}{4}$ inch of its point, it may be thrust into the prominent part of the tonsil, the cutting edge being directed

inwards, so as to avoid danger to the internal carotid artery. The opening of large abscesses may be imperative, as death has occurred from suffocation caused by their pressure or by the pus being discharged into the air passages, especially during sleep, or by the supervention of œdema of the glottis. Tracheostomy may be demanded, but the indications for its performance are very rare indeed.

Cocaine, 4 to 6 per cent. solution, should be well swabbed over the tonsils and pharynx before the knife is used, and the local anæsthesia produced by it will enable the surgeon to insert the index finger against the swollen tonsil, whilst the fingers of the opposite hand are made to cause firm pressure against the tonsil from without at the angle of the jaw as he feels for fluctuation. As the abscess has been often known to burst during the act of vomiting, it has been suggested that an emetic should be given with the view of causing its rupture.

Where the acute septic inflammation extends to the opening of the larynx, œdema must be promptly met by scarifying the parts or by intubation or tracheotomy.

The treatment of enlargement of the tonsils may, for convenience, be here referred to.

The first step in the treatment should be to remedy the constitutional condition, of which the chronically inflamed or hypertrophied tonsils may be regarded as the local manifestation.

In many cases this will be found to be associated with the tubercular diathesis, and the various agents found useful in the treatment of chronically-enlarged strumous lymphatic glands may be tried with the view of reducing the lymphatic growths in the tonsils. Iodine internally, combined with Iron and Cod Liver Oil, and Hypophosphites, sea air, good food, and the various remedies mentioned under Scrofula, upon page 872, should be resorted to with some hope of success, even in very indolent cases.

Local astringents, as the Glycerin of Tannin, may be painted night and morning over the tonsils, but the result is generally disappointing. Tincture of Iodine or Perchloride of Iron may be painted on twice a day; but of all applications the writer has obtained the best results from the following applied twice daily by means of a large camel's hair pencil.—

R. *Tinctura Iodii* ʒiij.
Glycerini Aluminis ʒj. *misce.*

Fiat applicatio. M. d. n.

Where the iodine causes nausea or irritation the plain glycerin of alum may be used, or the iodine may be replaced by ʒ drachm of the Glycerin of Carbolic Acid. Alum in fine powder may be insufflated, or the recesses of the tonsils may be filled up with it.

but, as a rule, this treatment causes so much discomfort and yields so little apparent benefit, that it is given up very soon. Gargles in every form are useless, save in allaying attacks of acute catarrhal inflammation upon the top of the old hypertrophy.

Hemenway recommends the mild continuous current for flabby tonsils, with the negative electrode on the tonsil.

Where constitutional remedies and the local agents fail after a reasonable time (say three months) to make an impression upon the size of the organs, operative measures are clearly indicated. Injection of the gland with Carbolic Acid, Iodine Trichloride, and other agents has been carried out, but as yet with results not very satisfactory. Puncture, after Cocaine has been used, may be tried next. The fine point of the galvano-cautery at a dull, red heat is to be pushed into the tissue of the gland in several places. This treatment is to be practised every third day for about a month. Barrett carries out this method till he destroys the greater part of the gland. Adenoids should be removed at the same time.

Where failure ensues the tonsil should be removed, or the hypertrophied growth sheered off. This can be readily done by seizing the gland on its inner aspect by a forceps or vulsellum, and slicing off a sufficient amount by a sharp blunt-pointed bistoury, with the blade protected by lint or plaster for about $\frac{1}{2}$ of an inch from the point, the incision being made upwards and inwards. The 'guillotine' is, however, nearly always used. By this simple contrivance any depth of growth can be removed without danger. The writer had, however, experienced difficulty in using it where the tissue of the tonsil was very tough and firm, until he learned by applying with his index finger pressure from without to steady the swollen gland before the advancing blade of the instrument; by this plan the worst cases are easily sliced.

As a rule, the hæmorrhage is slight, and is easily checked by sucking small lumps of ice, but if severe is best stopped by the galvano-cautery, or by strong solution of Perchloride of Iron, or better still, by seizing the bleeding point and twisting the vessel with the torsion forceps. Where the hæmorrhage is formidable, ligature of the external carotid may be imperative. The Suprarenal Extract applied locally, or hypodermic injections of Gelatin may be resorted to.

Ruault, by strong specially-devised cutting forceps, clips out pieces from the surface of the tonsils bit by bit instead of slicing. See under Phthisis, page 743, for the relationship of diseased tonsils and tubercle. See also under Laryngitis, Pharyngitis, and Hoarseness.

Malignant disease of the tonsil has been studied by Newman, who reports several cases. The tumour has been removed through the mouth by caustics, guillotine, curette, ligature, écraseur, cautery, incision, and electrolysis. It has also been removed by external incision. A previous tracheotomy is often necessary. Barker has also reported successful cases.

TINEA.

Under this term is included Ringworm, as it affects the different parts of the body. Thus, when the parasite—*trichophyton tonsurans*—infests the beard it generally receives the name of Tinea Sycosis, and its treatment is detailed under Sycosis on page 910, but it will be observed that there are two varieties of that affection, the remedies suitable for each being detailed.

Recent researches prove that there are at least two distinct parasites which produce ordinary ringworm—the *trichophyton* and the *Microsporon* Audouini. When ringworm affects the body, it is generally spoken of as Herpes or Tinea Circinata and the treatment of this condition may be first detailed, as it is simpler than when the parasite attacks the hairy scalp—*Tinea Tonsurans*.

In ringworm of the body almost any antiparasitic remedy will suffice to stamp out the disease in a very short time if in the early stages. The writer, in a pasture-land district, had a very large experience of this complaint upon his entry into the profession. The disease is communicated directly by cows, and often assumes a formidable appearance in those individuals contracting it directly from the animals. Even in severe cases he noticed that the scalp and hairy parts of the face were very rarely affected, and a few applications of the Ointment of the Iodide of Sulphur $\frac{1}{2}$ drachm to 1 oz. lard very soon caused its destruction.

Of the hundreds of agents used against tinea, there is none to be compared with this for quickness of action and efficacy. It has, however, its drawbacks, especially when rubbed into sensitive skins, as it causes eczema and often severe irritation. The thin skin of the agricultural labourer, exposed to the various vicissitudes of an out-door life will bear an ointment of 1 in 8, but the clerk or school-girl may suffer from the application of even quarter this strength.

As stated under Sycosis, this ointment should be very carefully compounded, and it is best to have it prepared for some time before being used. When these precautions are taken the Iodine Ointment may be used for some time without causing much irritation and it will be found exceedingly satisfactory in all forms of the disease.

Laniment of Iodine often suffices after a few applications.

Chrysarobin Ointment is also highly efficacious, and Unna's compound ointment is the best form. (See page 939.)

Oleate of Mercury, Citrine or White Precipitate Ointments, Carbolic Acid, Iodine Ointment, Strong Acetic Acid, Creosote, Menthol, Thymol, Corrosive Sublimate, Sulphurous Acid, Gunpowder made into a paste, even Writing Ink, and, as already stated, almost any of the hosts of parasitocides, suffice to destroy ringworm on the smooth parts of the skin. The physician must always remember that the eczema produced by these agents may remain long after the parasite is dead, and it is liable to be kept up for an indefinite period as long as the use of the remedy is persisted in. It is thus not a rare occurrence for patients to present themselves to a physician who are suffering from the abuse of agents long after the necessity for their application has passed away. The cessation of the irritating ointment or lotion, and the application of a little lard, lanoline, or oil, suffice in a few days to demonstrate the nature of the case.

When the parasite attacks the hairy scalp the treatment of the disease will often weary the patience of both physician and victim. If seen to at the very beginning of its progress, prompt treatment will sometimes prove nearly as satisfactory as in ringworm of the body.

The Ungt. Sulph. Iod. may be tried with every hope of a speedy cure if the parasite has not already got a good start in its march towards the recesses of the hair follicles. Before applying remedies the hair must be carefully clipped as short as possible over and around the diseased area. At a later stage shaving and epilation may be necessary. The R.P. Ointment is then to be rubbed into the spots, the margins receiving a fair share of attention, the application being repeated as often as possible without causing undue irritation.

In about ten days the applications may be discontinued, and as the irritation caused by the remedy subsides, a fair idea of the success or failure of the battle will be obtained by a careful examination of the hairs in the affected region. If these show the characteristic stumpy, broken, and irregular appearance, it is clear that more radical measures are necessary.

The great majority of cases presenting themselves for treatment for the first time will be found in this stage. If many such spots exist, it will be advisable to clip or shave the entire scalp, but the irregularly-formed hairs or stumps must be removed singly or in limited groups by pulling them out with epilation forceps. This process will require many repetitions during the tedious treatment of all bad cases and it will be necessary to teach the nurse or relatives of the patient how to perform it skilfully.

After epilation the Ungt. Sulph. Iod. may be rubbed in; and as the object of the physician is now to cause irritation or blistering, so as to loosen the remaining stumps and permit the remedy to get into the recesses of the tissue, a stronger ointment than that of the B.P. may be resorted to. It may be necessary at intervals to cause actual vesication by repeated applications of Blistering Liquid or

of the strongest Acetic Acid. Poultices or warm fomentation may be employed for the removal of the scabs caused by the blister, after which the parasiticide may be freely rubbed in. This treatment, coupled with epilation and a thorough washing of the scalp once every week or ten days, will in time eradicate the disease.

As long as a single broken or brittle hair-stump remains the affection if let alone will break out again. At this stage it will be necessary to go over the diseased area with a lens in a good light and as soon as the young, well-formed downy hairs are found sprout over the region, hostilities may be suspended and the patient permitted to mix amongst other healthy children.

To the student the treatment of this affection is most perplexing, chiefly because of the hosts of different agents recommended by every specialist urging the superiority of some particular parasiticide; and it must be clearly recognised that it is not to any great degree in the choice of the drug which he selects, but to his skill and, above all, to the patience which he exercises in its use that success depends. Though the writer begins and ends the treatment of ringworm with the Iodide of Sulphur in most cases sometimes during the progress of the disease this agent may be left aside and less irritating substances substituted. A close study of a few typical cases from day to day will soon show him what variations are necessary in the remedies or in the manner in which they are to be employed. It is advised sometimes to change the remedy after another every week or fortnight till the disease vanishes and the writer has heard a celebrated specialist recommend physicians to "ring the changes" till a remedy is lighted upon which will destroy the parasite. This is not to be seriously accepted. It is only by the constant observance of the action of a few good agents, when employed under the ceaseless change of conditions such as take place in chronic tinea tonsurans, that skill in the treatment of this affection can be acquired.

Oleate of Mercury ointment (5 to 20 per cent.) may be used from the very beginning, and it gives excellent results, and in many cases it is preferable to the Iodide of Sulphur in thin-skinned patients.

Crocker uses an ointment of Oleate of Copper, 1-4 drs. to 1 oz. lard.

Some of the French physicians adhere to the application of one per cent. ointment of Protochloride of Iodine in Lanolin rubbed in after spraying the scalp with warm water and thorough drying, and they affirm that epilation is never needed under this treatment.

Vidal maintains that the parasite is aerobic, that all that is necessary is to deprive it of oxygen and it must die, and that this can be achieved by covering the part with Vaseline. Nevertheless he uses a weak Iodine Ointment (5 grs. to 1 oz.) and covers the gutta-percha tissue. He is probably correct in his assertion that

but the experience of every physician proves that ringworm of the scalp may cease to grow but still may exist for many months or years under a layer of greasy ointment or pomade.

Thun, with more reason, maintains that ringworm of the scalp can be certainly cured by agents which do not destroy or even lower the vitality of the spores, and this he has ably demonstrated to take place under the use of Croton Oil. He has shown that spores which are soaked in the pure oil grow luxuriantly after their removal from it, and he has satisfied himself and many others that it is the irritation or inflammation produced by ringworm remedies and not by virtue of their parasitocidal properties that they cure the disease in the scalp. Croton Oil is, however, liable to cause much irritation, and baldness may result from it.

If the views of Thun be correct there is no difficulty in seeing how the Iodide of Sulphur acts so efficiently, but even if these views are to be accepted as correct it still stands to reason that such an agent should *more quickly* destroy the disease than a pure irritant.

Harrison recommends a prophylactic pomade for the heads of all children in a house where ringworm has broken out. Its formula is—Ointments of Eucalyptus and Boracic Acid, of each 2 oz., Cocoa Nut Oil, 2 oz.; and Oil of Cloves, half a drachm. He strongly recommends the following ointment for the established disease:—Caustic Potash, 9 grs., Carbohc Acid, 24 grs.; Lanoline and Oil of Cocoa Nut, of each 4 drachms, perfumed with Cloves or Rosemary.

Hutchinson's plan of treatment is undoubtedly a good one in all very chronic cases. He advises the hair to be shaved or cut close, and the scalp to be washed well twice a week with a tea-spoonful of Liquor Carb. Deterg, in a pint of water, and the following ointment to be rubbed in once or twice daily according to the effect produced:—

R. *Chrysarobini* ʒj.
 Hydr. Ammon. Chlor. gr. xx.
 Lanolin. Purif. ʒj.
 Adip. Benzoi ʒvj.
 Liq. Carb. Deterg. ℥x. misc.

Fiat unguentum.

He wisely states that "the secret of success consists in the patient continuance of the same remedy. I usually promise with great confidence a cure to the persevering, but never a rapid one. It is only the impatient who are disappointed. Those who change every few weeks from one remedy to another find ringworm almost incurable." He further states that he has never seen chronic ringworm resist careful and persistent applications of

Chrysarobin. Unna also depends upon it. The formula for Unna's ointment is Chrysarobin 5 parts, Ichthvol 5 parts, Salicylic Acid 2 parts, Simple Ointment 88 parts. Bertarelli employs Pitch Plaster for epilation before applying the Perchloride of Mercury.

Carbolic, Boracic, and Salicylic Acids, Tar, and Sulphur B.P. Ointments have been used by some who consider time no object. They will cure if persisted in, and cause very little irritation. The same may be said of Oil of Cade, Oil of Naphtha, Ichthvol, Thymol, Menthol, and nearly every essential B.P. Oil. Even Cod Liver Oil has its list of cures when applied locally.

Some authorities reject greasy applications altogether and adhere to watery or spirituous solutions, and these appear to do well in some cases. One of the most drastic applications is that of Quinquad. He applies it daily after shampooing the head -

R. *Hydrarg. Bimioduli* gr. iij.
 Hydrarg. Perchloridi gr xv.
 Spl. Vini Rectif. 3x.
 Aqua Destillata ʒviij. *misce.*

Fiat solutio.

After applying this he cures all the diseased spots, and in a week he epilates and applies a plaster of the Bimiodide of Mercury.

Cavafy's Lotion is used in the early stages of superficial but extensive ringworm of the scalp. Its formula is -

R. *Acid Boracici* ʒj.
 Ether. Sulphuric. ʒj.
 Spirit. Vini Rectif. ʒv. *misce.*

Fiat solutio.

This should be sponged over the affected spots several times a day. It is of no use whatever when the disease has already invaded the hair bulbs.

The Liniment of Iodine is, perhaps, the best of all the liquid preparations. Very inveterate spots may be touched occasionally with Iodized Phenol (1 oz. Iodine and 4 oz. Carbolic Acid), or with Coster's Paint, consisting of Iodine 120 grs. and Light Oil of Wood Tar 1 oz. Strong Acetic Acid is sometimes used all through the treatment when oily or greasy preparations are objected to, and every known soluble parasiticide drug may be used in the form of lotion.

Morris, when the disease is seen early, applies 5 grs. Salicylic Acid dissolved in 1 oz. Chloroform. He says it loosens the hairs, dehydrates, dissolves the fats, and attacks the fungus, and if

applied before the fungus gets to the deeper parts of the follicle rapid cure may be effected if no fatty substance is used.

Sulphurous Acid is frequently employed and Hyposulphite of Sodium and Formalin, but they do not penetrate to a sufficient depth. This is the objection to watery solutions—viz., that they do not penetrate into the bottom of the hair follicles.

When lotions are employed, the scalp should be washed daily, and the best way to do this is to employ Borax instead of Soap in the water used for washing.

Shoemaker's method of treating ringworm of the scalp deserves special mention. He condemns cutting, shaving, epilation, and blistering as worse than useless, and begins the treatment of a case by sponging the diseased spots over with a weak Alcoholic Solution of Thymol, Borax, Naphthol, or Mercuric Chloride, and then thoroughly saturates them with a 50 per cent. Solution of Boroglyceride, which latter remedy he feels cannot be too highly extolled. It is mopped on with a brush, and rubbed in with the fingers. If this fails, without epilating he proceeds to rub in the Ointment of the Oleate of Copper, prepared with either 4 or 9 parts of a fatty base. A little only need be applied. In chronic cases he alternates this treatment with applications of the Oleate of Mercury of 5 per cent. strength for children, and 20 to 30 per cent. for adults.

He states that he has never once seen salivation produced by this remedy though he rubs it in twice daily for weeks till the parasite is completely extirpated.

In the form of ringworm of the most chronic and inveterate type where the parasite has got down deep into the hair follicles before the disease has been noticed, and where it is scattered over the entire scalp in very small detached spots here and there, the treatment is most tedious and disheartening. A modification of Aldersmith's method may be tried in such cases. The scalp is to be searched over with a lens, and wherever a stumpy hair or small group of such appears, the spot is to be touched with a very fine camel's hair pencil dipped in Croton Oil. This should be done for several days in succession, and if free pustulation does not occur, a warm linseed poultice may be applied over all.

This method is very different from the routine application of the Oil to large tracts of the scalp, a plan, though efficacious in many instances, is, as already mentioned, liable to be followed by severe irritation and even baldness. The suppuration around and in the minute spots causes the broken hairs to be protruded from their sockets, as in the variety of ringworm known as kerion. As a final touch to the parasite, a strong Oleate of Mercury Ointment may be rubbed into each spot.

In tinea kerion nature has already almost effected a cure, and the inflammation caused by the parasite has led to the falling out of most of the hairs. In this case epilation of the remaining loose hairs, and the application of a weak Perchloride of Mercury or a

strong Lead and Opium lotion, suffices to speedily perfect the cure. Boroglyceride does well in these cases.

During the entire period of treatment the patient's head should be covered by a small silk cap, and rigid precautions are to be taken, especially in the case of schools, where each child should have separate sleeping accommodation, with washing and toilet requisites.

Living warns against the use of greasy or sticky prophylactics, and insists upon the head being well washed daily with warm water and soap, but Hutchinson believes that it is to the decline in the fashion of using greasy pomades that the prevalence of ringworm is now due.

In schools, the writer depends upon a pomade or oil containing crude Petroleum Oil, and the immediate application of the Ointment of the Iodide of Sulphur to all suspicious spots as they appear. Hutchinson recommends his own treatment highly in the case of schools, but the writer has had experience of the Iodide of Sulphur in several outbreaks of ringworm in a large charity school and he believes it cannot be improved upon.

Though there is not so much in constitutional treatment as many writers claim, nevertheless, successful management of chronic cases may not be possible until the general health is improved. This is especially true in those cases where troublesome eczema or impetigo complicates the disorder. Cod Liver Oil, Quinine, Iron, Arsenic, and other tonics, in combination with pure sea air and good food, may be tried.

Where the finger nails are attacked by the parasite, they should be scraped thin, and a solution of Liquor Potassæ (50 per cent.) be brushed on, followed afterwards by Spirit Lotion containing 1 per cent. Corrosive Sublimate applied under oiled silk.

TINEA VERSICOLOR—See Pityriasis Versicolor (Page 745).

TINNITUS.

The treatment of this sometimes distressing symptom will depend entirely upon the cause. Thus, where wax or any foreign body lies against the tympanum, its removal is followed by instant relief.

In throat affections and in Eustachian obstructions air must be permitted to enter the tympanic cavity. Inflammation of the middle or internal ear may give rise to it. (See Ear Diseases, page 252) Though any local cause sufficient to produce irritation of the acoustic nerve or alterations in the local blood pressure will commonly produce tinnitus, it must not be forgotten that it may

be reflex—produced by dyspepsia, renal, and hepatic diseases, and by the irritation arising from decayed teeth, etc.

Where the symptom is associated with Menière's disease, or where it arises from incurable local conditions or from central nervous affections, some relief may be obtained from a combination like the following:—

R. *Sodii Bromidi* ℥ss.
 Liquor. Fowleri ℥j.
 Spt. Ammon. Arom. ℥ss.
 Aquæ Camphoræ ad ℥xii. *misc.*

Fiat mistura. Sumat ℥ss. ter in die ex cyatho vinario aquæ post cibos.

Chloride of Ammonium alone, or with Bromide of Ammonium in doses of 15 grs. each, has often given relief in the writer's hands in very chronic cases. Locally, blisters behind the ears or Veratrine Ointment may give relief; sometimes air charged with Vapour of Chloroform injected into the Eustachian tube for a time dispels the discomfort.

Quinine and Salicylates have been recommended, pushed to the extent of producing slight physiological symptoms, and a combination of bromide of soda and salicylates often does well. Hypodermics of Pilocarpine, $\frac{1}{2}$ grain and less, have sometimes given much relief, and the writer has recently obtained good results by placing a small hypodermic tabloid under the tongue.

TONGUE—Diseases of.

Under Cancer, upon page 117, the treatment of malignant affection of this organ is briefly detailed.

Removal of the entire organ may be achieved by the use of the cætereur through the mouth, or through an incision in the floor of the mouth, so as to apply it as far back as possible. The galvanocætery has also been used, but both these operations are now not so frequently done, owing to the sloughing of the tissues following them. The cætereur is, however, still much used in conjunction with the knife and scissors, as the hæmorrhage is more under control by its use. Thus Baker splits the tongue for its entire length through the middle line. After cutting all the muscular and mucous attachments of each half with scissors, he then draws it well forward by stout threads passed through each half and lays the cætereur on well behind the diseased structure. Each half is removed separately. He employs stout whalecord instead of the chain.

Whitehead excises the entire organ by means of scissors only. The tip is well drawn forward from the gagged mouth by a strong thread passed through it. After snipping through the frænum

and all the muscular and mucous attachments, the organ is easily removed with but slight hemorrhage, the lingual arteries being tied or twisted as they are cut, and a ligature through the base is left in for a day.

Many complicated operations are planned for the removal of the organ after dividing the lower jaw. Those of Syme, Langenbeck, Sedillot, Bilroth, Regnoli, and Kocher are done in this way. All modern operators make it a routine practice to clear out the submaxillary triangles, whether secondary deposits can be felt at the time of the operation or not. For this, as for similar manifestations of malignant disease elsewhere, the tendency is toward very early and very thorough removal.

The floor of the mouth should be well packed with iodoform gauze, and the powdered drug dusted freely over the stump several times daily. Cheyne endeavours to prevent sepsis by injection of 20 c.c. of Antistreptococcic Serum 36 hours, and a further dose of 10 c.c. 12 hours before operation. He also pays careful attention to the cleaning of the mouth for 3 days before removing the tongue. Butlin lays the greatest stress upon the importance of keeping the mouth aseptic and thus preventing pneumonia, &c. After operating by Whitehead's method he feeds by the rectum or with a stomach-tube for a short time, and has only had one death in 46 cases.

Food is administered by a rubber oesophageal tube and by the rectum. Hemorrhage may be controlled by ice, by the pull-tail, or by pressure.

Inflammation of the tongue is to be treated as described under the article Glossitis, upon page 323.

Superficial ulcerations are to be dealt with as mentioned under Stomatitis, upon page 889, and under Aphthae, page 57.

Syphilitic affections of the tongue are to be treated by the rules and principles mentioned under Syphilis page 916. Ulceration may be freely touched with the Acid Nitrate of Mercury, or with the solid caustic stick.

Hypertrophy of the tongue or macroglossia has been, when of limited extent, successfully treated by pressure in a few cases. Any concentrated astringent solution which does not produce irritation may be applied on strips of lint wrapped around the enlarged and protruding organ. Over these, strips of Tangle-Plaster may be placed so as to exert moderate pressure in a uniform manner.

In some instances when the tongue can be retained inside the mouth, benefit has been obtained by pushing it back and keeping the jaws together by a rubber or other bandage passed over the head.

As a rule, where the enlargement is great, the question of operation will have to be met. This may be done by the knife, visors, *écraseur*, thermo- or galvano-cautery. A few stout needles are passed through the enlarged organ in front of the spot where

the section is to occur, the tip being well pulled forward, the écarateur is laid on, and the anterior portion of the tongue removed.

Where the deformity is not so great the favourite operation is to make a Λ shaped incision, and remove the wedge of tissue by the knife or scissors, after which the edges of the incision may be brought together by a series of deep and superficial wire sutures after any bleeding vessels have been secured and twisted or ligatured with catgut. When the surgeon has the choice of time he may defer operation till about the end of the fourth month, but where feeding is rendered difficult he must operate sooner.

All authorities who have written upon this peculiar malformation recommend the administration of Cod Liver Oil, though it does seem to the writer very difficult to conceive how it can possibly do any good.

Neuralgia of the tongue is a rare disease; but, by a strange coincidence, a typical case presented itself to the writer when engaged in writing this brief article on diseases of the tongue. The only hope in this affection of any permanent relief will lie in the persevering use of the remedies mentioned under *Neuralgia*, upon page 592. Beginning with large doses of Quinine, combined with Chloride of Ammonium and a little Morphia, the various anti-neuralgic agents should get a fair trial, whilst, by improved food, change of air, freedom from worry and other ills, the general health is brought up to the highest standard. A weak continuous current passed through the organ gives good results, if steadily adhered to, and relief has been known to follow even a few applications of the battery.

Locally much may be done to afford ease. Cocaine dissolved in Glycerin (12 grs. to 1 oz.) may be tried, or tabloids of Cocaine, or lozenges of Carbolic Acid.

The writer has found the following combination give almost instant relief:—

R. Cocaine Hydrochlor. gr. xx.
Glycerini Boracis ℥j. misce.

Fiat applicatio. Signa—"A little of this liquid to be brushed over the tongue every hour or two hours during the day, and always a short time before taking food."

In the instances of this affection which have come under the writer's notice, the pain was so much aggravated by movements of the tongue that the patients were compelled to keep it at rest, and this led to retained secretions filling the floor of the mouth. To prevent this it will be necessary to wash out the mouth frequently, and the best wash for this purpose is a weak Carbolic Acid Lotion. Condy's Fluid may be tried when there is any decomposition. The sensitiveness of the tongue interferes with

the feeding, and hence it is well to have the food administered in the liquid form. Section or stretching of the gustatory nerve may be resorted to when the ordinary anti neuralgic remedies fail.

The injection of various anodyne solutions, as Morphine &c. into the substance of the tongue is not to be recommended, but a full dose of the last mentioned drug may have to be administered under the skin below the lower jaw if the paroxysms of pain become very severe.

Bathin recommends the local application of Menthol.

The peculiar condition of the tongue known under the various names of *Psoriasis*, *Ichthyosis*, *Tylosis*, *Keratosis*, and *Leucoplakia* and regarded by some authorities as of the same pathological nature as corns or callosities, gives little satisfaction to the therapist.

It resists drugs, and often resents interference of all kinds, and finally may become the seat of a disease not to be distinguished from epithelial cancer. The keynote to treatment lies in the fact that this affection is often the result of the action of an irritant, either in the form of a ragged decayed tooth, or it may be produced by smoking or drinking alcoholic liquids, probably by these practices combined. Hence the extraction of any irritating tooth, or teeth, or the hling down and polishing of their crowns, and total abstinence from tobacco and alcohol should be insisted upon. Very hot liquids are likewise to be forbidden.

Solutions of Bichloride of Mercury, Lactic Acid, and Chromic Acid have been recommended. Rosenberg states that he obtains results which he describes as "wonderful," by pencilling the tongue with a 20 per cent. solution of Iodide of Potassium: the patches disappear in a few days. Leistikow applies a paste of 22½ grs. Terre Silica, 45 grs. Resorcin, and 1 oz. Lard seven times a day.

Excision of the patch, when this is small, gives the best results, but all authorities are agreed that caustics only increase the mischief.

The galvano-cautery may be used to advantage in some cases.

Tongue-tie is remedied by the simple operation of snipping the frenum, which is generally resorted to much more frequently than is necessary. The most satisfactory method of operating is to pass in the index finger and the next one under the tongue, the frenum being put upon the stretch between them, and with curved scissors, the point being held downwards, the constricting band is divided by a single snip, care being taken not to divide the ranine vessels as the child struggles. (For the treatment of Ranula, see page 832.)

TONSILS.

The treatment of inflammation and enlargement of the tonsils is detailed under Throat (Sore), upon pages 941—945.

TOOTHACHE.

This is but a symptom of caries, periostitis, exostosis, impaction of a wisdom tooth, inflammation of the tooth-pulp, or other local cause, which must be carefully distinguished from neuralgia. When possible, the cause is to be found out and remedied, and in the great majority of cases this will be found to be owing to irritation produced by caries. Thus in children when the pain is excited by hot or cold water, sugar, salt, &c., and is not increased by pressure on the tooth, it is evident that the nerve is exposed. The best treatment in such cases is to very gently syringe the cavity out with warm water and insert *without pressure* a little cotton wool saturated with Creosote or Carbolic Acid, which after a few applications causes the death of the pulp. Sometimes Chloroform, or Oil of Cloves may be advantageously used before resorting to the acid.

The packing of the pulp-cavity with drugs in the dry state is sometimes resorted to. Thus Cocaine, Chloral, Butyl-Chloral, Camphor, Menthol, Morphine, Opium, Antipyrine, or Exalgin, may be placed in the hollow, and kept in position by a little cotton wool loosely packed upon the top.

In adults where there is very severe pain originating in the living pulp of a carious tooth, the most satisfactory method will be to remove any stoppings, if such exist, or to gently remove any carious dentine till the pulp-cavity is well exposed, and then by a minute quantity of powdered White Arsenic left *in situ* by a plug of cotton wool the vitality of the pulp will be entirely destroyed. Chloride of Zinc and Nitric Acid or solid Nitrate of Silver may be used in the same way.

Tomes points out that for the relief of pain a dead tooth should be left quite open and a live tooth sealed closely up. This is seen where the pain results from pus in the pulp-cavity. No relief can be expected till the pulp-cavity is opened up and the matter evacuated, and further tension prevented by leaving a way for free exit.

The best routine local anæsthetic for relieving the pain of an inflamed pulp-cavity is a mixture of Carbolic Acid and Collodion. This obliterates sensibility, and seals up the chamber if applied carefully upon cotton wool. Cocaine may be combined with the Acid. It will be remembered that this application should not be used to seal up a dead pulp-cavity in a tooth where acute pain is produced by some inflammatory action in the neighbourhood of the tooth or in its roots.

R. Collodin B.P. ʒiij.
 Acidi Carbolici (Cryst.) ʒiij.
 Cocainæ Hydrochlor. gr. x. mssc.

Fiat solutio. Signa—"A small portion to be applied upon cotton wool to the dried-out pulp-cavity of the painful tooth."

Where severe pain is caused by septic absorption from a dead pulp, the only remedy which affords any immediate relief is extraction of the dead tooth. If the pain be not very severe however, relief may be obtained by injecting pure Carbolic Acid through the dead pulp down into the hollow fangs or root canal.

The popular remedies for external application are of little use, and the plan of rubbing Aconite, Belladonna, or Chloroform along the gums does more harm than good. The anti-neuralgic remedies internally are also not to be relied upon as long as the local conditions remain unattended to. It is hardly necessary to rest upon the importance of saving the tooth. Extraction should only be resorted to when the disease in the tooth substance is so extensive to permit of the hope of a solid stopping being inserted after the subsidence of the acute symptoms.

It is almost impossible to exaggerate the importance of the treatment of dental caries, as so much harm is done by the absorption of pus and microbes from the cavities of suppurating teeth. In many instances of dyspepsia, ear disease, tuberculous adenitis, &c., the first step should be the clearing out of these culture grounds. Turner insists upon the importance of sacrificing every temporary tooth and the first permanent molars rather than leaving a child with painful or foul teeth in its mouth, and he even mentions septic endocarditis as a condition which may arise from neglect of this rule. The writer has had brilliant results in dyspepsia in young subjects by no other treatment than the extraction of a series of foul suppurating teeth. (See also page 743.)

Chewing of Pellitory Root sometimes relieves the pain depending upon congestion of the fangs or of the periosteum.

Extraction may be the only means of giving relief where the pain is caused by the impaction of a wisdom tooth. If possible, the wisdom tooth itself should be removed, as it is generally much less valuable than the molar in front of it, but this latter may have to be sacrificed if the wisdom tooth cannot be brought within the grasp of the forceps.

TORTICOLLIS.

As this condition arises from several distinct causes, the treatment cannot be commenced till the cause at work is thoroughly made clear. In those cases occurring soon after birth where a hard tumour can be felt along the course of the sterno-mastoid muscle, the deviation of the neck is clearly owing to the rupture of the muscle during labour. The writer has seen a considerable number of these cases during many years practice in the extern department of a children's hospital, and he has never known an instance where the affection did not pass away completely. Friction with any mild lubricating oil or the Liq. Pot. Iod. Cum Saponē, and the envelopment of the neck in a

thick collar of cotton wool, always was followed by disappearance of the tumour and of the deformity.

Where wry-neck is *spasmodic*, it presents sometimes one of the most obstinate complaints that can come before the physician. This acquired form has been submitted to a great variety of treatments. As a rule, it may be laid down that mere tenotomy is never successful, and that very often it considerably aggravates the deformity.

Stretching or resection of a portion of the spinal accessory nerve has succeeded sometimes in spasmodic torticollis, but it has also failed, nevertheless the division and removal of $\frac{1}{2}$ to 1 inch of the nerve, though sometimes unsuccessful, must be regarded as the only surgical remedy holding out any reasonable hope of cure. The writer had a case in which this was done by A. B. Mitchell. The improvement was slight for the first three months, after which the patient got steadily and slowly better, and is now—four years after the operation—quite well.

Nurectomy of the spinal accessory should certainly be advocated in every severe case, and when it fails the nerve supply of the other affected muscles should be dealt with. Often complete success follows this secondary operation when excision of the spinal accessory in a previous operation had entirely failed. Chiene recommends trephining and the removal of a portion of the cerebral cortex when these measures fail, other authorities support this recommendation, believing that the affection is always centric. The mere adjustment of an apparatus with the view of tiring out the opposing muscle has been tried, and in a few cases has succeeded, but, as a rule, it fails, and during the period in which it is tried the patient often suffers great discomfort.

Some surgeons have reported successful cases after division of the tendon or muscle through an open skin wound. This is the best method, as the surgeon is enabled to divide every tense structure, and any hæmorrhage can at the same time be easily arrested. Collier reported a very interesting and successful case in which he cut down and placed a loop of silver wire upon the spinal accessory, twisting the ends to ensure slight compression, and leaving the ends of the loop protruding from the wound. The entire sterno-mastoid muscle, or a portion of it, has been removed in some cases by Kocher, who maintains that this gives better results than nerve excision.

Galvanism has been beneficial in some cases, but its failures are much more numerous than its successes. Gowers never found any benefit from it, even when applied for long periods. It must, however, be persevered with for some time. There are various plans for using this agent. The best is to begin with a very mild *continuous* current to the affected or constantly contracting muscle for 15 minutes three times a day, and when the spasm is controlled to educate the patient to use the affected muscle in various ways, as in turning the head in different

directions. Fifteen Léclanché cells will suffice, with one pole (the positive) near the mastoid bone and the other near to the clavicle.

The opposing muscle is generally found weak, and it should have the interrupted current passed through it from time to time, in order to cause lively contractions, massage being employed twice a day. By increasing in this way the tone and power of the weakened antagonising muscles, and controlling or modifying the spasm in the affected sterno-mastoid and other muscles, great good or permanent cure may be obtained in some cases. This plan has succeeded sometimes in the writer's hands in mild cases in young subjects. Absolute rest in bed with the head upon a low pillow and spoon-feeding, as in cervical caries, has been credited with some successes.

Bromide of Potassium in large doses, with Arsenic internally, may be always tried, and some cases have been reported as cured by the hypodermic injection of Gelsemium. Weir Mitchell recommends very large doses of this latter drug, so as to produce very pronounced physiological action. He begins with 3 minims of Wyeth's Fluid Extract three times a day, till eight times this amount is taken.

Curare has been injected, Conium and Indian Hemp, Valerianates, and Asafetida given in large doses, and Hyoscine administered, but their effects rapidly pass off. They may be used, however, to great advantage when other means, as galvanism, are having a trial.

Gowers has found the best results from Morphia hypodermically, and it has been often curative, but only when used for long periods and in full doses, and he warns that it comes to be the choice of two evils, (1) the relief of the spasm or its cure, (2) the establishment of the morphia habit. $\frac{1}{2}$ to 1 gr. daily must be given for months, and the patient should not pass out of the physician's hands till he undergoes treatment for the morphia habit.

In syphilitic cases cure has sometimes followed brisk mercurialisation.

In those cases of false torticollis, following old disease of the bones in the neck, tenotomy is generally of much value. The tenotome is entered a little above the clavicle, and both portions of origin may require to be cut. After the wound has healed exercises are to be commenced, and carried out with great persistence, whilst massage is to be done two or three times daily.

TRACHOMA—See Conjunctivitis (Page 161).

TRANCE.

Under Hysteria on page 437 the treatment moral and mechanical for the condition which generally underlies trance will be found. If the state of trance be not very "deep," the treatment described under Catalepsy will be successful. Electricity in the form of a strong interrupted current should be used in all cases, and when

there is any evidence of a return to half-consciousness the battery should be at once applied to the arms and legs. Snuff, strong Ammonia, Nitrite of Amyl, &c., may be used at the same time, but they are of little value in genuine trance. When these measures are used at the same hour each day, as Gowers recommends, there may be induced a tendency to periodical waking, which will ultimately culminate in a cessation of the attack. Till then every attention must be paid to the maintenance of life. Feeding should be carried on by the rubber tube of the stomach-pump, introduced through the nose or mouth.

Rectal alimentation may be essential also in prolonged cases. Strong tea and coffee are indicated.

By the judicious application of warmth and skilful nursing much may be done to minimise the exhaustion sure to follow, especially in those cases where food cannot be administered.

Antispasmodics, as Bromides, Musk, Valerian, Asafoetida, Sumbul, and other anti-hysterical agents may be given by the bowel or by the nasal tube, but they do little good, and the first-mentioned drug may do harm.

Reasoning from the observation that Strychnine so often aggravates the abnormal sensations complained of by the hysterical patient, the writer believes that the best drug treatment in this affection may be found to be the steady administration of strychnine by the hypodermic syringe with the view of increasing the sensitiveness of the nerve centres and the peripheries of the sensory nerves and nerves of special sense. He has never had the opportunity of testing the drug.

TRICHIASIS—See under Entropion (Page 277).

Epilation of the irregularly growing hair may be all that is required in mild cases to give temporary relief, but as the hair grows again the trouble is almost certain to return.

The hair bulbs must be destroyed. This is most easily accomplished if there are but a limited number of them producing the mischievous lashes by inserting a needle into the hair follicle connecting it to the negative pole of a battery, whilst the positive pole is placed over the skin in the vicinity of the eye; a current such as is produced by three or four ordinary cells, passed for half a minute or so, is usually sufficient, but some dexterity is needed to insert the fine needle exactly in the follicle, as otherwise the operation is useless.

Where a considerable number of the hairs are at fault the best plan is to make two parallel incisions along the margin of the lid and to carefully dissect out the hairs and their hair-bulbs.

The operation of transplantation is to be performed when the entire row of hairs is faulty: it is done by splitting the lid along its marginal surface between the hair-bulbs and the Meibomian follicles and excising an elongated or elliptical piece of skin from

the outer margin of the eye-lid and fastening the cut surfaces by sutures, so as to draw away the ingrowing hairs (page 278).

TRICHINOSIS.

The preventive treatment of this serious disorder is practically all that need be considered, as we know of no agent which will destroy the parasites once they have become encapsuled in the muscles. In the case of food it is satisfactorily proven that there is no chance of the disease being communicated if the cooking has been very thorough, and it must be remembered that trichinae may find their way into the human body, not only from the uncooked flesh of the pig, but also from that of eels and pigeons. A temperature of 160° F. will destroy the parasite, but it will resist freezing for considerable periods, and the process of curing by the ordinary brine solutions has no effect upon it. If the statement be true that the temperature in the middle of a leg-ham after boiling for two hours only reaches about 92° F. it shows how little reliance is to be placed upon ordinary cooking.

After the ingestion of trichinised food in the stage in which nausea, vertigo, diarrhoea, and fever are present, the best treatment will be to clear out the stomach by means of a good emetic followed by a large dose of some smart purgative, as 1 or 2 ounces of Castor Oil, 10 or 20 grs. of Calomel, or 2 or 3 ounces of Blue Draught or White Mixture. The only drug likely to be of any use in the early stage, before the parasites have left the intestinal canal, is Thymol in doses of 15 to 30 grs. every two hours for three or four times. The colon should be thoroughly irrigated and the parasites have been found for weeks coming away in the washings. These may be repeated for two or three weeks. Fever is afterwards to be combated by the administration of small doses of Antipyrine, and every effort made to keep the patient's strength supported by means of absolute rest in bed and by feeding with peptonised foods in order to tide him over the period of acute danger, whilst the progeny of trichina-embryos are migrating into the muscles. Rectal feeding may be necessary, and free supply of stimulants are called for in some cases.

The administration of anthelmintics or of antiparasitic agents like Arsenic, Picrate of Potash, Corrosive Sublimate, Salicylate, and other powerful drugs may do much harm, but can do no good, and by universal consent their use is now discontinued, reliance being placed upon supporting treatment.

TRISMUS—See Tetanus Neonatorum (Page 939).

TUBERCULOSIS.

The broad question of the treatment of tubercle has been already discussed under Phthisis and other headings. In former editions of the present work much space was given to the con-

sideration of Koch's lymph as a remedy.' The agent is now almost discredited, though some authorities hope that its marvellous selective power may yet be utilized in the treatment of tubercle.

A considerable amount of interest is still taken in this agent, and McCall Anderson has recently reported most favourably upon the value of the improved preparation—i.e., Tuberculin R. in phthisis. Others however, have reported nothing but failures, and the price of the maximum dose (17 shillings) is practically prohibitive. As a method of dealing with tubercular disease of joints and bones the injection of small quantities of Tuberculin is still recommended by some Continental surgeons, but this plan is rapidly becoming obsolete.

Le Peigne's goat's blood and Richet's dog's serum methods have now only an historical interest, but several authorities still continue to use the anti-tubercular serum of Maragliano, and Dr Renzi states that after its use the tubercular patient ceases to respond or react to tuberculin. There is little to be said of Viqueral's donkey serum, Paquin's horse serum, and Emmerich's sheep serum, and Liebreich's Cantharidinate of Potash cure has followed into obscurity the numerous vaunted specifics which preceded it.

Sidney Martin, in his exhaustive article on Tuberculosis in Allbutt's system, concludes with the melancholy statement that 'There is no specific treatment for tuberculosis. Nothing has yet been discovered to counteract the invasion of the tissues by the bacillus tuberculosis. Prof. Ruata (*Medical Annual*) states quite recently that "remedies given by the mouth are useless, and for two thousand years have not saved one single consumptive person from death. To be effective, they must be diluted beforehand in our fourteen pints of blood, and till now we have no medicine whatever which could be prescribed in such a concentrated form as to destroy the specific bacillus without first killing the less resistant cells of which our body is formed."

Notwithstanding the truth of these statements, it is most encouraging to turn to the Registrar-General's Statistics of the death rates in England, which show that the deaths from consumption have fallen from 26.8 for every 100,000 inhabitants to 14.6 during the last fifty years.

The mortality of pulmonary phthisis is certainly and rapidly diminishing under improved sanitation and the open-air treatment. Surgery is achieving results in the treatment of tubercular peritonitis, lymphatic tubercle and lupus, which are little short of the marvellous.

Finsen's Phototherapy in tubercular disease of the skin has opened up a view of possibilities in the treatment of other tubercular lesions full of hope. In former editions of this work many methods of attacking tubercular disease by injections into the tissues or into the blood of various antiseptic substances were described. Most of these are now discarded. Where they have

stood the test of time they will be found described under *Phthisis*, *Lupus*, or other heading.

Lannelongue's plan of injecting deeply dilute solutions of Chloride of Zinc into the tissues surrounding tubercular deposits has not held its ground. He maintains that by this method the bacilli are rapidly "fixed" and destroyed, the tissues for a considerable distance becoming sclerosed and finally absorbed. He injects a few minims of a 10 per cent solution of the Zinc Chloride into numerous points around the tubercular zone. It is reported that lymphatic growths rapidly shrivel up and disappear under this treatment.

Under the different headings of *Phthisis*, *Scrofula*, *Peritonitis* (Tubercular), *Lupus*, *Caries*, *Mesenteric Glands*, *Orethritis*, *Meningitis*, *Joint Diseases*, &c., &c., the treatment of tubercular affections will be found.

The present activity in the recently created lay and professional organisations for the prevention of tuberculosis augurs well for the success of the campaign, which is now earnestly engaging the attention of all scientific men, against this terrible scourge. As remarked under *Phthisis*, the recent statements made by Koch in which he denies the identity of human and bovine tuberculosis has attracted keen attention, and his view that no measures need be taken against the spread of tubercle by the milk, butter and flesh of tubercular animals has been received with amazement in this country. (See page 743.) Already Professor Hueppe in the *Berliner Klinische Wochenschrift*, August, 1901, strongly protested against such conclusions, and exposes the fallacies of Koch's reasoning. He quotes the interesting fact that Weleminsky has demonstrated that micro-organisms taken in with the fluids are more likely to be attracted to carious teeth and tonsils than to the intestinal wall. From the tonsil he points to the danger to the pulmonary tract. Clinical observation is most decidedly opposed to the statements of Koch about the comparative rarity of infection of the intestinal tract. Heller, including *Tuberculosis mesenterica*, puts the incidence of tubercular intestinal lesions in children as 50 per cent, and points out that when the cows are kept on the pastures around the German Alps, raw milk being drunk indiscriminately, far less tuberculosis appears than when the cows are cooped up close in stalls, where they obviously carry the infection from one to another.

TUMOURS.

Under various headings the treatment of tumours are referred to throughout this volume, as under *Ovary*, *Diseases of*, *Spermatic Bristle*, *Lymphatic Glands*, *Nævi*, *Hydatids*, *Cancer*, *Sarcoma*, &c., so that any general remarks here are unnecessary.

The removal or non-removal of tumours, both innocent and malignant, and the best methods for removal in each particular

case, are to be laid down upon general surgical principles, after the anatomical and clinical peculiarities have been fully recognised.

TYLOSIS.

Where the increased or hypertrophied epithelium is situated upon the skin, the treatment to be adopted is that noticed under Corns and Callosities (page 175). In tylosis of the tongue, the measures detailed under Tongue Diseases, upon page 956, are indicated.

TYMPANITIS.

The treatment of this symptom will depend entirely upon the causes producing it. The treatment of these has already been detailed under their various headings, so that no further notice here is necessary. The reader is referred to the articles upon Dyspepsia, Intestinal Obstruction, &c.

Where the causes are not removable, agents may be employed in each case suitable to the condition of the patient. Thus, in hopeless cases of abdominal obstruction from cancer, where colotomy or other operation is contra-indicated, the abdominal wall and intestines may be pierced by a fine aspirator needle, and the imprisoned flatus let free. As a rule, this affords but little relief. A much better plan is to make a small opening in the middle line, and, having secured the first coil of distended bowel presenting, to open this and leave it *in situ* in the abdominal wound. Elsewhere the writer has stated his experience of the uselessness of the long tube introduced into the rectum. Enemata of Turpentine, Creosote, Asafetida, and the internal administration of these agents at the same time, alone, or combined with Galbanum, Musk, Ammonia, Alcohol, Charcoal, Ginger, Capsicum, Cajuput, Peppermint, &c., may be tried.

TYPHILITIS.

The treatment of this condition will be found detailed under Pertyphlitis, upon page 656.

TYPHOID OR ENTERIC FEVER.

There are few diseases in the entire range of medicine in which so much has been done to reduce the mortality as in the affection under notice.

It will be seen, however, that not in drugs, but in skilful nursing, dieting, and other measures, is our faith to be centred. At the outset, it will be recognised that the siege may be a very long one, and arrangements must be made accordingly. Perhaps there is no single factor or combination of factors, of such vital importance in the treatment of typhoid fever as the *period or stage in the disease* at which the case is placed under treatment. The earlier the stage in which the measures about to be described are brought to bear upon the patient the greater is the probability of a successful issue.

The application of *Widal's* test in the early diagnosis of the disease is of great importance, and cannot fail in reducing the mortality, as it often enables the physician to insist upon the patient taking to bed without waiting for the symptoms of the advanced disease.

The sick room should be selected by the physician and it should be quiet, well ventilated, large, and airy, with abundance of light which can be easily cut off when desired. Where a very large room can be obtained it should be selected, even in winter, and with a few screens placed around, but at a distance from the bed an agreeable aspect of comfort can be easily produced. The less furniture the better, and carpets should be removed, their place being taken by a few thin rugs.

Jenner's plan of having two rooms, one for the night and one for the day is theoretically a good one, but in practice a dangerous one, owing to the serious consequences which may arise from moving the patient about. It may however, be adopted in those cases where two good rooms open directly into each other the patient and his bed being carried (not rolled) from the one to the other. An upstairs room is preferable (this is most desirable in typhus), and the question of having an open fire, night and day will be settled by the state of the weather, &c. The temperature of the room should be kept at about 60° F.

There should always be two moderately small beds of precisely the same height from the floor, so that, when drawn up exactly alongside each other, the patient can be shifted from the one to the other as safely as from one part of a large bed to the other. There is nothing so suitable as a firm straw pallassie, with a good hair mattress upon the top. A wire mattress, instead of the straw pallassie, is preferred by some, as being cooler, but it lacks in firmness. The bed should be so placed—not in a corner—as to permit of the nurse and physician being able to walk all round it. Everything in the shape of hangings is to be forbidden. The bed-clothing must be light and it is a good plan to replace the ordinary counterpane by a linen sheet, which can be frequently renewed. Mackintosh sheeting underneath is to be regarded as a questionable adjuvant.

The services of two good skilled nurses, one for the day and the other for the night, are to be secured when possible and it should be insisted that they regularly keep up a written report or journal of the temperature, bowels, doses, nourishment, &c.

In summarising the effects of different treatments and in arriving at a conclusion about the advisability of altering any of the details of treatment in a case, it is essential for the physician to have a chart before him giving him a graphic or bird's-eye view of the variations in the temperature, &c.

The patient is to be put to bed at the earliest possible moment and from thenceforth till convalescence, a position of absolute rest is to be maintained throughout his illness. The bed-pan and

the urinal must be used always. Cases where perforation, hæmorrhage, and death have followed the exertion of the patient's getting up to the night-chair are numerous. It must, however, be acknowledged that the bed-pan is the greatest difficulty in the nursing of typhoid fever, some patients cannot tolerate its use, and in some rare cases the physician may feel himself compelled to select the lesser of two evils, and permit the patient to be assisted to the night-chair. Ewart points out the importance of keeping the patient as much as possible lying in a position of slight inclination towards the left side. This is effected by putting a bolster under the right side of the mattress, so as to prop the body forwards, or by raising the two right feet of the bed on blocks whilst the patient lies on his back, the object being to cause emptying of what he calls the cæcal pool—i.e., the retention of the liquid faeces in the right iliac fossa, which he believes causes the toxic typhoid state.

A draw-sheet should be constantly worn, and scrupulous cleanliness insisted upon. It is a good plan to have the motions disinfected by some antiseptic as Chlorinated Lime, Terebene, &c., as soon as they are passed. One of these may be placed in the urinal each time before being used.

Diet is of the utmost consequence; indeed, except, perhaps, in the case of diabetes, there is no affection in which the question of dietary is of such vital importance, and the young physician must recognise that there is no point in connection with this subject which he can afford to regard as too trivial for his consideration. Few men can be in practice long without being able to testify to the disastrous or fatal consequences which occur from the patient's indiscretion in this matter. A good rule to have ever before the mind is to forbid every form of food all through the attack, except such as would *readily pass through the meshes of a fine sieve*. Not that it will be necessary to sift any food, but to have clearly before the mind of the patient and nurse that only substances in the liquid form or those containing impalpable powders are admissible.

Milk meets all requirements for the majority of patients, and when they can take it, which is nearly always the case, there need be little trouble about the dietary in the early and acute stages of the disease. It is needless to say it should be pure and fresh.

The quantity should, for adults, be not less than three or four pints in the twenty-four hours. Some patients will be found who can take and digest twice this amount, and when very large quantities are taken it may be advisable to skim it occasionally.

The method by which this liquid nourishment is to be administered is of quite as great importance as is the quantity. It must be given in small amounts at short intervals, so as to prevent the patient filling his stomach by a large drink. A wine-glassful every hour would represent three pints in the twenty-four hours; but, then, in ordinary cases the patient should not be disturbed frequently during the night, and, therefore, double this amount

may have to be given during the day and evening. The nurse must, therefore, be permitted to use her discretion according to the individual peculiarities or tastes of the patient, the main idea being adhered to that, as far as possible, the total amount of nourishment should be as evenly as possible divided over the time. In the early morning the patient generally needs his food most, and in typhoid and typhus fevers in their advanced stages the diet of the patient may be depending upon the conscientious discharge of the nurse's duties in this particular.

The opposite extreme must be guarded against. There is nothing but injury can follow the administration of quantities of milk beyond the digestive powers of the patient, and the physician by inspecting the motions from time to time can gain valuable information upon this point. It is hard to hit off the requisite amount necessary, but upon the whole it will be better to err a little on the side of giving too much. The milk may be given warm, cold, or even iced to suit any strong inclination upon the part of the patient. It will be better to give it iced when possible.

Soda, kali, or plain carbonated water may be mixed with it in varying amounts according to the requirements of the case. It is desirable to give an occasional draught of water or iced water when the patient craves for it, the only objection to this is when water or ice is allowed to take the place of nourishment in patients who have little appetite, as may often be seen in the case of children. One sound system of treating typhoid fever consists in the administration of large quantities of water with the view of promoting elimination. It should always be kept in mind that the patient requires water in some form, and hence the necessity for diluting his milk. Yeo recommends Semmola's glycerine drink as an occasional remedy for thirst and dryness of the throat; it is made by mixing 1 oz. glycerin and 30 grs. citric acid with 1 pint of water. It may be better to double the acid and water where there is much thirst.

The question of peptonising the milk is one which must be considered, and it is the opinion of the writer that it is not advisable to adopt this as a routine practice in every case. With patients possessing good digestive powers it is generally unnecessary, and sometimes turns them against the food. An inspection of the motions may settle the question. If much firm curd, and in liquid motions the undigested flaky coagula are clearly visible the diet must be altered. Either the patient is not being fed at proper intervals, or he is having more than it is possible for him to be expected to digest, or else his digestive powers are weakened or else the irritability of the bowel is hurrying its contents too rapidly along the canal to permit of digestion and absorption.

A little reflection will dictate the best course in such cases. Lime water or kali water may effect the desired change by its action upon the milk, and occasionally barley water is agreeable. Sometimes a change to weak tea or cold chicken jelly

may set matters right, or a little good arrowroot may be boiled with the milk, or a very pure isinglass may be added.

If the patient's vital powers are low the milk may then be peptonised by adding a little of the *Liquor Pancreaticus*. In such a case the question of stimulants will have to come to the front, as will be presently discussed, and if these are indicated the requisite dose of brandy or whiskey may be mixed with the milk before administration. This latter plan often succeeds better than any other even in those cases where the patient occasionally vomits solid curds.

In cases where milk cannot be taken in sufficient amount, the question of liquid animal food must be considered. Some physicians give beef tea and soups in all cases as a matter of routine. These certainly may be given in typhus always, but in many cases of typhoid fever they excite or increase diarrhoea, and may do harm.

In many cases, and, indeed, in nearly all cases at some period of their progress in typhoid fever, beef tea, strengthened by meat extracts, and good soups, carefully strained, are advantageous.

The equivalent of one pound of butcher's meat made into beef tea may be given during the twenty-four hours alternately with the doses of milk in most cases from the very beginning. If care be taken to suspend its administration upon the onset of diarrhoea. Constipation is often present throughout the attack, and it is then that the value of animal soups is most apparent.

The routine custom of the writer in hospital and private practice is to adhere to milk till constipation declares itself, and then either to suspend the milk entirely for a time, or to give an equal amount of beef tea or strained chicken soup alternately with it. At a later stage an occasional dose of mutton broth, carefully strained through a fine sieve and deprived of all fatty matters, will prove a substitute for Castor Oil or the enema. Raw beef juice and barley and oatmeal gruels well strained, are praised by Ziemssen. Calves-foot jelly and gelatin blanc-mange are admissible, but only in cases where the patient is able to take a sufficient amount of milk or other valuable nourishment. Rennet, with a little carefully-prepared currant jelly or strained fruit juice, may be permitted.

When any change from the pure milk diet is made the temperature chart is to be closely scanned, and it will be often observed that the rise which sometimes follows can be attributed to the animal food.

Starchy foods are not to be employed except under special circumstances. They do not appear to be digested easily in typhoid fever, and diarrhoea has often been the result. The writer enters a protest against eggs, though their use is advocated by Murchison, Cayley, and others. He has seen them so frequently excite intestinal irritation and favour decomposition or fermentation in the alimentary canal that he has of late years given up their use as a food entirely in all stages of typhoid. In the convalescent

period eggs seem to act in the opposite way, and to produce an obstinate constipation. Ziemssen thinks that three eggs ~~per~~ are enough.

After the subsidence of the fever the physician will be tempted to permit a change in the diet. In contemplating this it will be advisable to summon up the mental picture of the possible state of the ulcerated Peyer's patches and solitary glands. It will be advisable to refuse the patient's request for solid food for 10 or 12 days after the normal temperature has been reached.

Boiled white fish is, perhaps, the first solid meat which can be safely permitted, with tea or weak coffee, in which any plain food may be soaked. Oid advises a return to solid food at an early date if the patient clamours for it. He states that he has learned to give in to this strongly stated desire upon the part of the patient for solid food. The writer has not yet learned to do so.

Medicines are of very secondary importance in mild uncomplicated typhoid fever. As yet we do not know of any agent capable of cutting short the attack at any stage of its existence. Much interest has been excited by the discovery that the serum of animals rendered immune to any of the zymotic diseases contains a substance capable of neutralising the zymotic poison when injected into another animal suffering from it. Various attempts have been made to treat the disease in man by sterilised, attenuated bacillary cultures, by the serum of immune animals, and by serum drawn from patients recently recovered from the disease; but the results have upon the whole been unsatisfactory. Jez immunised guinea pigs by intraperitoneal injections of the typhoid bacillus, and administers an extract made from their crushed organs to patients suffering from the disease; the results were reported as satisfactory. The value of the injection of attenuated cultures as a preventive, and of their influence upon the mortality of the disease in those who had submitted to them but were afterwards affected by the fever, will be mentioned later on (see page 987).

Calomel in 10 grain doses was much used, and still is in some places on the Continent in the early stages, with the view of cutting short the disease. Liebermeister gave three or four such doses during the first 24 hours, and was satisfied that he caused the attack to abort in a number of cases. There is no doubt that calomel is one of the best of intestinal antiseptics, and some authorities give it in small doses (1-2 grs. once or twice daily) for this reason all through the attack without using any other drug. The older plan of giving emetics and drastics has now been ~~long~~ exploded.

There seems every reason to hope that an agent will be discovered which will be found to cut short the disease. When such a discovery is made it will be probably found to be some well known remedy used upon a new plan.

Boric Acid was tried by the writer as a routine treatment, and it promised very well, but he eventually had to discontinue it as

the doses which he hoped would prove useful, owing to its disturbing effect upon the stomach. He is totally at a loss to comprehend the reports of Tortchinsky, who treated 240 consecutive cases by giving 10-15 grs. 3 or 4 times a day, and states that no untoward effects were ever noticed from the acid.

Hydrochloric Acid, in 15 to 20 minim doses, diluted with 1 oz. water, is the most popular, agreeable, and harmless drug which can be used in the routine treatment of this fever, typhus, or small-pox. It acts as a febrifuge only by virtue of its effects upon the parched tongue, mouth, and throat, whereby it increases the salivary secretion, and in the stomach supplies an element probably very deficient in febrile conditions. Moreover, it forms an agreeable medium for the administration of other drugs indicated in the various complications which may arise during the course of the disease.

Yeo uses Chlorine as a routine treatment, and his formula is—15 grs. powdered Chlorate of Potassium are put into a 12 oz. bottle, and 60 mins. strong hydrochloric acid are poured in, and the bottle corked and shaken till it becomes filled with yellow fumes; water is gradually poured in, and frequently shaken, so as to absorb all the gas. To the full of the bottle of solution he adds 24 to 36 grs. Quinine and 1 oz. Syrup of Orange, and of this he gives 1 oz. every 2, 3, or 4 hours, according to the severity of the case. The writer has seen excellent results from this treatment in hospital, but patients often object to it after a time. Sulphurous Acid appears to act in a similar manner as an intestinal antiseptic; 10 mins. diluted may be given every 3 or 4 hours.

There is scarcely a known antiseptic agent which has not been tried in this disease, from Corrosive Sublimato or the Bimodide down to the Carboic Acid compounds, each in its turn earning a doubtful reputation. It would profit little to take up our limited space with a rehearsal of the hopes and disappointments caused by the reports and trials of these so-called abortive specifics.

Thymol, Camphor, Turpentine, Chloroform, Alpha-Naphthol, Naphthalin Dioxide, Naphthaline, Betol or Naphtholol, Naphthol or Beta- or Iso-Naphthol or Hydronaphthol, and several other bodies of this series are still being tried. Clarke states that the best intestinal disinfectant is Hydronaphthol, given in doses of 2 or 3 grains in the form of a pill coated with kolatine, every two or three hours or it may be given suspended in milk. Petherut and others give larger doses—up to 60 grains daily. Little need be said of the Continental method of giving large doses of Iodide of Potassium; it has met with few advocates in this country. Urotropine has been extolled by Horton-Smith, who recommends it as a routine treatment ($\frac{1}{4}$ dr. daily). It certainly causes the bacillus to disappear from the urine.

Salol produces intestinal asepsis when given in fair doses, and Carbonate of Guaiacol and Carboic Acid have their enthusiastic advocates. Ewart strongly advocates Wedgwood's mercurial

treatment, which consists of 20 mins. Liq. Hyd. Bichlor. (about 4 grains), 15 to 20 mins. Tr. Ferri Perchlor., 1 dr. Syr. Aurantii & Syr. Limonis in 1 oz. water every six hours, and he affirms that anchelation always takes place and that he has never once seen salvation.

The antipyretic treatment of typhoid fever is a large subject, and very contradictory views are held by different authorities. The agents employed in this method may be divided into two groups—viz., chemical antipyretics and hydropathy. The former class will be discussed first. It contains a host of agents, and includes all the new and old drugs possessing the power of reducing fever heat, such as Quinine, Antipyrine, Antifebrin, Salicylates, Picric acid, Guaiacol, Eucalyptus, Lactophenin, Creosote, Thalline, Picric acid, Salicylate of Quinine is supposed by many to be an ideal drug in this disease, combining in itself both treatments, i.e., the antiseptic and the antipyretic.

Before referring to the relative values of any of these agents, it must be stated that there are still some who maintain that the fever heat is conservative, and, if checked, the patient is either injured or the attack prolonged. Though the writer has not seen much to encourage him in the routine employment of antipyretic drugs in typhoid or other continuous fever, nevertheless he is perfectly satisfied that the principle of combating the fever now is a perfectly sound one. It is only with the imperfections in our present agents the fault is to be found. As soon as a perfectly innocent antipyretic, possessing slow but continuous action is discovered, then there may be safely predicted a great drop in the mortality of the continued fevers. Quinine has been long used for this purpose, but for producing a definite and marked depression of very high fever temperature it is, perhaps, the least reliable of all our agents. It has, nevertheless, great advantages over its rivals in some respects. Thus its powerfully tonic properties and its slow but more steady and continuous action, when carefully administered, make up for its deficiencies in other respects.

In the writer's hands it has generally failed in satisfactorily reducing the fever heat when this has been very high—i.e. when approaching to 105°, except in the case of children. This experience may be partially accounted for by the fact that he has generally only resorted to it in bad cases, and then it very often fails entirely. Its best effects are to be obtained in conjunction with hydropathy. Less than 30 grains will be of little use, and sometimes the dose may be repeated three or four times at the twenty-four hours without appreciably telling upon the temperature.

At this point it may be well to remark that hyperpyrexia cannot be safely treated by any known antipyretic drug.

There is a group of cases where a moderately high and sustained temperature persists for many days in which Quinine often acts

fairly well if given steadily at the rate of 5 grains three or four times a day for about a week or more. Its good effects may be proved in these cases by suspending it, when the temperature will generally be found to rise again. There can be little doubt that it is beneficial if it be only capable of keeping down the heat steadily for 1 or 2 degrees. In the case of children a 5 grain dose often lowers the temperature 3 or 4 degrees. It is best given in wafer paper. Upon the whole however, Quinine, as a routine antipyretic remedy, is not very satisfactory, and where the temperature is very high it is useless. Occasionally it excites severe vomiting and distressing cinchonism. Yeo insists upon the value of Quinine in small doses, 2 or 3 grains in solution, especially with Chlorine. He condemns the large doses of the solid drug.

Digitalis is open to the same objections, and also labours under the great disadvantage of proving poisonous when given in large doses; its proper place seems to be when given in combination with moderately large doses of Quinine—10 grains of Quinine and 30 minims of the Tincture.

Antipyrine seldom fails to make a very decided impression upon the temperature. The same is also true of Antifebrin. By these agents a drop of 4 or 5 degrees can be easily and constantly effected. Formerly 30 grains of Antipyrine were given, followed by 15 grains in one hour or half an hour, and 15 grains again inside another hour if the temperature had not fallen. By this plan it was not unusual to see a fall of 8 or more degrees. Dangerous collapse has often followed these doses, which are now generally abandoned. 10 grains or even 5 grains of Antipyrine, or 3 or 4 grains of Antifebrin every four, five, or six hours, is the usual method of administering these drugs, and in a few cases the physician may be able to satisfy himself that he can, by this plan, keep the temperature within bounds. He will, however, far more frequently find that after the drop there will be a marked tendency towards a greater rise, and after altering the doses and changing the length of the intervals, he soon begins to find that the depression and profuse sweating, and other untoward effects, produce greater mischief than any good obtained by their antipyretic action.

A very important result of which the writer has satisfied himself repeatedly is the unevenness of the effects of these agents in the same patient during different days of his illness. Thus, a severe typhoid case which bore 20 grains of Antipyrine well for several days was almost snuffed out by a 5 grain dose given at a later stage. He has also seen one case in which a single grain of Antifebrin would keep the temperature depressed for 24 or 36 hours, though this patient at first bore moderate doses well.

Where, owing to some passing complication, the temperature rises so high as to threaten exhaustion during the middle of a typhoid attack, these agents are of value in reducing the fever heat, and assisting the patient through the additional danger, but

in keeping steadily down the temperature for any length of time in a severe continuous high fever, their value is open to doubt. Antifebrin appears to exert a more continuous effect but its cyanosis and other symptoms which occasionally follow are great drawbacks.

Phenacetin, Salicylates, Malakine, and the newer antipyretics do not appear to give any more promising results, but though their action in cutting short the attack is yet to be proved and their failure in keeping the temperature uniformly reduced is recognised, it cannot be questioned that the employment when carried out judiciously, of the different members of this class of agents may occasionally greatly aid the patient in his struggle against the disease. His general distress may be much relieved and paroxysms will be soothed and sleeplessness may disappear along with headaches and anxiety, by their occasional exhibition.

Hydropathy in the routine treatment of typhoid fever has excited great attention of late years. The effects of the cold tepid bath in reducing the fever heat with certainty, safety and precision is becoming more and more clearly recognised. In the severe cases or in hyperpyrexia there is really no other method of treatment available, as the agents just mentioned are not to be relied upon. About this there cannot be any difference of opinion, but when we come to consider the advisability of employing the cooling bath as a routine agent in all cases of the disease differences of opinion still exist, but it may be truthfully said that under clearer knowledge and more improved methods of administering this agent, and a steadily diminishing rate of mortality these differences are disappearing. There are, therefore, many reasons to tempt one to believe that the routine administration of cold or tepid water as an antipyretic will become as generally practised as is the rest and liquid diet treatments, except in the very mildest cases.

The plan first carried out by Brand is still adhered to in bad cases, but for routine use it is variously modified. He places the patient four to eight times a day, after a small dose of stimulant, in a bath of water at a temperature of about 68° F. for 15 to 25 minutes till he feels chilled and begins to shiver. A very important element in the bath treatment is the constant friction employed, the limbs and thorax being rubbed all the time, and cold compresses applied to the head. Ten to 15 minutes suffice and brisk reaction should always be looked for. His temperature is 102.2° F. in the rectum. As soon as the thermometer reaches this height the bath is ordered. When the mercury registers a drop of 2½ degrees he is to be taken out of the bath, all the surface of the body save that of the abdomen being wiped dry. He is then put to bed, and a little hot stimulant given. Very mild cases will not come under this rule, as the temperature may never reach 102.2°. Lichermaster recommends the routine use of the bath only when a temperature of 103° is reached.

The mortality under Brand's treatment has fallen from 15 or 20 per cent to 3 or 4 per cent. Taking all the different reports from favourable and unfavourable reporters, one is safe in saying that the *routine* employment of the cold bath has diminished the mortality by 25 to 50 per cent.

There are many modifications of Brand's treatment, and some of them are improvements. It is demonstrated that a *cold* bath is unnecessary, and many have obtained excellent results with water at a temperature from 90° to 95° F. The higher the temperature of the patient the lower should be that of the bath.

Ziemssen highly praises the bath at about 90° F. He advises that the water in it should be constantly stirred, and that the patient's body be wholly immersed in it. It should be gradually cooled down to 80° F. by pouring in cold water at the patient's feet. The duration of the immersion should be over 15, but not exceeding 30 minutes. By this plan, which has been much practised, the prejudice against the dangers of cold water is removed, and the sensations of the patient are much more pleasant. Shock is avoided.

Always, however, in hyperpyrexia—a temperature of about 68° or 70° should be employed, but the very cold or ice bath should be condemned. Ziemssen uses a *warm* bath in adynamic cases.

Under the cool bath the heart beats more vigorously and slowly, and the pulse improves in tension, whilst appetite and digestion are greatly assisted, but it does not seem that there is any proof that the ulcerative process is altered in the intestinal regions.

Anuschat strongly advises warm baths instead of cold. He insists that it is the water, and not its temperature, which is the most important factor. His baths vary from 95° to 90°, under which last figure he does not go, even if the temperature reaches 105°. He claims that decided improvement sets in in three or four days of treatment. There is almost entire absence of secondary symptoms, and a much shorter duration of illness, 145 out of 150 patients being less than four weeks and many less than three weeks in bed.

Upon the other hand, some physicians insist upon the value of cold affusions very frequently repeated. The writer has resorted to this method when a bath was not available, the patient being enveloped in a thin sheet, and cold water poured freely over him.

Barr has employed a tank about 6 × 3 × 1 feet, lined with lead, and filled with water varying from 90° to 98°. In this he keeps the patient for a period of one to four or more weeks. A blanket is wrapped round the body, and a pillow to keep the head above water, and a half lid to the tank constitute the machinery for carrying out this treatment. There is the great difficulty of the bowels, which he permits to be relieved in the bath, the water being made antiseptic. Success has been reported as the result of this—not very æsthetic—method of treatment.

Simple sponging of the body in detachments has been resorted

to by those who believe in the antipyretic treatment, but who are afraid to insist upon the cold bath. The wet pack is even better, and there is no doubt that systematic sponging patiently with cold or tepid water will bring down and keep down the temperature considerably. Sponging of the upper and lower extremities and the head and neck now constitutes a part of the routine in every case of the writer's where the temperature reaches 102°. Excellent results are obtainable by rubbing the limbs and then over with a large, smooth piece of ice, and this should be followed by friction with a towel or by hand rubbing.

The great difficulty in the use of the cold or tepid bath is the movement of the body which it entails. A simple appliance yet to be devised to obviate this. Every three or four hours, if the temperature shows a rise up to 102.2 (Brand), or to 103 (Liebermeister), will not be too often for a 15 minute immersion through the day and night. Severe hæmorrhage and great tympanites, peritonitis, with serious cardiac depression, are the only contra-indications to the use of the bath. The writer thinks that coldness of the extremities should be a contra-indication even when no other sign of cardiac failure is present. Renal complications appear to do well under the baths.

Recently attempts have been made to replace the cold water treatment of typhoid by cold air, and chambers have been designed where the temperature of the surrounding air and of the bed upon which the patient lies can be kept at a reduced level for hours or days. By means of tubular mattresses in connection with the pipes from a suitable freezing apparatus the local application of cold can be also effectively accomplished without the inconveniences and dangers of moving the patient, which are inseparable from Brand's method.

Alcohol.—The question of giving stimulants in typhoid and other fevers has been already referred to. There are certain general principles which will meet with almost universal acceptance, whilst some disputed points will be considered later on. The majority of cases do not require any stimulants at any stage of their progress. The routine practice of administering stimulants in fevers is growing gradually less and less. Seldom if ever are they indicated in the early stages of the disease unless in the case of those addicted to their habitual or daily consumption. A patient who appears to have the indications for alcohol during the first week of his attack will, in all probability, be beyond the influence of remedial agents. The writer does not hesitate to give alcohol when indicated in the way to be presently mentioned, and when he gives it, it is with no sparing hand, but he is decidedly opposed to it as a routine treatment. Statistics, if impartially considered, would seem to prove that the routine use of alcohol and the rigid exclusion of alcohol all round will bring the mortality to about the same thing. This may be put in either of two ways—

- (1) Either that alcohol is useless or unnecessary, or that it is at

least not injurious, since it does not lower, if it does not raise the rate of mortality.

(2) There is, however, another way in which to look at the unanimity of the two classes of statistics which may be nearer the truth and it is this:—Those who stoutly refuse to administer alcohol in all cases will probably lose some lives by withholding it, and those who give alcohol in every case will probably sacrifice some lives by its use. The number influenced will probably be a *very* small percentage of the whole.

Every case must, therefore, be weighed upon its merits, and a decision should only be arrived at after weighing the indications for and against, just in the same way as if opium, or calomel, or antipyrine were being discussed for administration to meet certain clear indications. The debatable question of giving alcohol as a food need hardly be discussed here, though there can scarcely be a doubt that a considerable portion of it is burned or used up in the body just as other foods are. A small percentage of cases may be improved, and the patient's chances of recovery increased by giving small doses of alcohol along with the milk food where there is good reason to believe that the digestive powers are weak, and where close observation proves in the case before the physician that the addition of a tea-spoonful of good whiskey or brandy actually does assist the digestion of other nourishment when given along with each dose of it or immediately afterwards. There are various indications which are relied upon as calling for alcohol in severe cases. These are mainly symptoms of cardiac failure, and those who place their faith in alcohol in such cases do so because, amongst other actions which it possesses, they believe alcohol to be the best cardiac stimulant.

A weak, unsteady, and easily-compressed pulse and a corresponding condition of the heart, with the typical symptoms of the "typhoid" state, are regarded as clear evidences of the necessity for alcohol. The writer has watched by the bed-side the effects of alcohol under these circumstances, and he has satisfied himself that by its use life may sometimes be saved when, without it, would be lost. The effect of the drug requires the closest watching, and herein lies the secret of success, because it may sometimes be found to do harm in the case where the indications for its use may appear clear, and it is the duty of the physician to give the case his anxious attention for the first 6 or 12 hours after beginning the alcoholic treatment.

Brunton in his clear and forcible style puts the case so:—"The various rules which have been given for the administration of alcohol in fevers may be condensed into one. If the alcohol tends to bring the patient nearer to his normal condition, it is doing good; if it takes him further away from his healthy condition, it is doing harm. The points which are usually specially attended to are the condition of the tongue, pulse, respiration, skin, and nervous system.

"If it is found that the alcohol (a) renders the dry tongue moist (b) slows and strengthens the pulse when it is too quick & quickens it when it has become abnormally slow, (c) slows the hurried respiration, (d) renders the skin cooler or moister when too hot and dry, and (e) lessens delirium and brings on sleep—then its action is beneficial. If it have an opposite effect it does harm. Useful indications regarding the advantage of alcohol and the dose may be obtained by the practitioner remaining beside the patient counting the pulse and watching the tongue respiration skin, and general condition of the patient for a quarter of an hour after the dose has been given. Particular care should be taken in the administration of alcohol to patients in the small hours of the morning. It is about this time that attendants are most apt to become sleepy and therefore careless, and just at this time also the external temperature is lowest, the fire is apt to get low, and the vital powers of the patient are most likely to sink.

The question of the dose and form in which the alcoholic stimulant is to be given is an important one. First, as regards the variety of alcohol, the writer believes that brandy or whiskey should always be preferred to wine, and the selection of brandy as against whiskey or vice versa, should be made after considering which of these agents can be procured in the purest form. As a rule, in this country a pure whiskey is more easily obtainable than a pure brandy hence the writer always employs whiskey, and is satisfied that the product of the patent still should not be employed. The so-called "silent" spirit and the numerous brands into which it enters do not produce the cardiac stimulating effect of a matured malt whiskey produced by the old pot still process. The ethers produced by the splitting up of the traces of fuel left in the latter process possess valuable stimulating properties and moreover they appear to aid in the entire combustion of the spirit in the blood. The whiskey can be given to the greatest advantage along with the milk, when the patient does not object to this plan.

As regards the dose, the symptoms and their severity and the ascertained effects of the agent must be taken into account along with the previous history of the patient.

The practice of the writer is only to give alcohol when clearly and urgently needed. Hence the dose which he generally employs will appear larger than that usually recommended. Two or three ounces in the twenty-four hours, as often mentioned by writers can be of no use in severe cases and in mild cases the patient will probably be as well or better without them. The only value that can come of such a small quantity is that already mentioned to aid in the digestion of the liquid nourishment.

Less than 5 ounces of old whiskey spread evenly over the twenty-four hours will be of little use to an adult in the condition indicating the exhibition of alcohol. In bad examples of the typhoid state, with a very fluttering pulse, dry tongue, and moist

covered with sordes, the writer has given twice and sometimes three times this quantity with the greatest benefit.

Wood states "That, properly administered, it always promotes, not arrests, secretion in these cases. The guide to the amount given should be the effects produced; so long as it lowers the temperature and pulse rate, moistens the dry tongue and skin, and quiets the nervous disturbance, it does good. If, however, the tongue grows drier, the pulse puts on an angry, bounding character, and the patient becomes restless and uneasy, stimulation is being pushed too far and the amount exhibited should be lessened. Whenever the colour of liquor appears upon the breath the patient is almost certainly taking too much."

Large doses of alcohol have a lowering effect upon the temperature, but it is out of the question to think of using it merely for this purpose in typhoid fever. Where the cold or tepid water bath is being used, a small amount of alcohol is considered necessary, and there is no reason why alcohol, quinine, and the tepid bath may not be all indicated in the same case.

Where complications exist, the choice of the form of alcohol may be determined by the nature of the symptoms present. Thus, where stimulants are indicated and the patient is vomiting, champagne may be selected instead of either brandy or whiskey, and if diarrhoea is a marked feature, the effects of a good old port wine may be tried.

Where the stimulant cannot be given mixed with the food, it should be administered in a very diluted form.

The writer in the last edition of his work on "Materia Medica and Therapeutics" thus sums up the Alcohol question in fevers.—Most authorities, however, would probably agree (1) that alcohol is not necessary at all in the majority of cases; (2) that often unpromising cases pull through without it; (3) that in severe cases it cannot be safely withheld from those habituated to it; (4) that occasionally by the use of alcohol life may be saved which would otherwise be lost; and (5) that it is rarely needed in the very large doses prescribed by some—8 to 10 oz. whiskey may be regarded as representing a liberal daily allowance.

Such, then, will be the routine treatment of typhoid fever, but complications must be met. They are the rule, a case without them being the exception. The management of the complications will now be briefly detailed.

HYPERPYREXIA should be promptly met by the cold bath, as already mentioned upon page 974. The antipyretic drugs are not to be relied upon.

SLEEPLESSNESS—This may prove a troublesome symptom in the disease from the earliest stage, and any of the usual hypnotics mentioned under Insomnia may be employed. The writer prefers a draught like the following:—

R. *Liquor. Morph. Hydrochlor.* ʒj
 Sodii Bromidi gr. xlv.
 Syrupi Auranti ʒij.
 Aqua Chloroformi ad ʒij. *misce.*

Fiat haustus. *Signa*—"The half to be taken at bed-time and the remainder in three hours if necessary."

When the sleeplessness depends upon headache, this should be relieved if possible first, and in such a case morphia or opium may aggravate it (see below). Chloral is a favourite drug with some physicians. The writer never uses it unless all others fail, and this is very seldom. In the late stage of the disease, or even more so of typhus, it is a dangerous agent, owing to the fatty degeneration of the heart, which for a time follows all prolonged high temperatures. Paraldehyde often acts well, and Trional a few drawbacks.

Sulphonal acts very well, but it should be given in solution. It can be easily dissolved in a large quantity of boiling water, and given when partially cold with a little stimulant.

The watery extract of opium or the tincture may be selected where we have a relaxed condition of the bowel as well as insomnia. The value of cold sponging when faithfully carried out by a conscientious nurse often surpasses that of any hypnothic drug.

HEADACHE—This is sometimes violent in bad cases at the beginning, and the following measures are those used by the writer—A Mustard Plaster behind the upper part of the neck and over the occiput, extending upon the sides as far as the base of the ears. A moderate dose (6 grains) of Antipyrine repeated in one or two hours. If relief be not marked clipping or shaving of the hair, and the ice-cap, or Leiter's tubes, and in very bad cases leeches may be applied to the temples. This will seldom be necessary, except in those *rare* cases beginning like acute mania.

The cold pack or bath, or tepid bath, or cold sponging, if the temperature be very high, generally gives speedy relief. Quinine often aggravates.

Do not it will, as a rule, yield to the same remedies as the headache in the early stages of the disease. Absolute quiet and darkness will aid the above-mentioned drugs. At a later stage the cause of the delirium must be sought for and removed when possible. Thus, it may be the first sign of a pneumonia meningitis, or even an intestinal hæmorrhage or renal complication. The writer has seen it yield to the emptying of an enormously-distended bladder which had been overlooked. Coma is to be similarly dealt with. The treatment of the typical typhoid state has already been referred to, the main agent being large doses of alcohol. In one case, where the delirium and coma of typhoid

fever rendered the patient's condition hopeless, the writer saved life by pouring in large quantities (1 oz. every hour) of whiskey through the tube of a feeding cup placed far back upon the root of the tongue, the power of swallowing being almost lost.

Musk in 3 grain doses may be given in such cases, and if the temperature is high, the cold bath after a hypodermic injection of ether or a rectal dose of alcohol should be tried. Cold affusion sometimes is very valuable in such cases if applied when the patient is lying in the tepid bath.

DIARRHŒA should not be interfered with unless the number of motions exceed four or six in the day, and not then if they be not large in amount and very watery. A careful inspection of the motions should be made in such cases, and, by a change in the feeding, the bowel irritation may be stopped. Undigested curd of milk or too much beef tea or soup may be the cause. The writer has seen the dilute hydrochloric acid mixture, as ordinarily given, produce diarrhœa. Peptonising of the milk, or the addition of whiskey or brandy, and the withdrawal of all meat extracts and starchy foods, may at once check it. Arrowroot boiled in milk, and made very thin, so as to be taken as a drink, may be tried before drugs. It is the only starchy food admissible.

Opium, to relieve the exalted peristalsis of the bowel, is the most reliable drug. With it may be combined some agent to effect intestinal antiseptis. Many authorities insist that the preventive and curative treatment of this complication or symptom should always be the administration of one or more of the intestinal antiseptics already discussed, and some always resort to calomel; Beta-naphthol, and Salicylate of Bismuth are favourites. The writer has of late years obtained excellent results from Tannalbin in 10 gr. doses, combined with a little opium.

The best form for the administration of opium is an enema of starch, of creamy consistence, not exceeding the capacity of a wine-glassful, along with 30 minims of laudanum.

Where there is irritability of the rectum, 20 minims of laudanum may be given every three hours or oftener by the mouth, and where vomiting occurs, the $\frac{1}{2}$ grain morphia perule may be given.

The old hospital mixture containing 20 mins. Acid. Sulph. Ar., 15 mins. Laudanum, 25 mins. Tincture of Catechu in each dose, is still a favourite with many.

In very obstinate diarrhœa, Lead may be given combined with the opium, 2 or 3 grs. of the Acetate, and 10 minims of laudanum after every loose motion. Tannin, Logwood, Chalk mixture, Rhatany, &c., and the host of astringents mentioned under Diarrhœa, upon page 209, have been given. Opium is by far the most reliable of them all.

Hot enemata are highly recommended by Geissler, who gives 20 ounces of water at a temperature of 108°s and reports that the number of stools are lessened and rendered less mucoid. Teissler,

of Lyons, employs a cold enema every six hours. Other authorities go in for irrigating the colon with various antiseptic solutions, but this is a practice not to be commended with our present knowledge. Shnell, however, recommends a very sound method available before ulceration sets in. He passes up to the sigmoid a soft rubber tube about 3 feet in length and washes out thoroughly the entire colon by a fountain enema with warm water sterilised by previous boiling.

CONSTIPATION is sometimes as troublesome as diarrhoea. After trying every method, the writer finds that where a beef tea and meat soup diet is not sufficient to keep the bowels right, a Glycerine suppository is very satisfactory. It can be given without any difficulty and generally acts in a short time. Where it fails a warm water enema may be given, and repeated as often as is necessary.

Drastics and all cathartics are strictly forbidden. The only aperient which is safe is Castor Oil, and the dose of this should not exceed 2 drachms at the outside. It should not be given if the constipation has lasted many days, until the rectum is washed out by a large olive oil and warm water enema. Eggs are not to be administered as they tend to increase the constipation.

HÆMORRHAGE is a very formidable complication which calls for Opium. In severe cases 30 minims of laudanum may be given by the mouth and if there be any vomiting present a hypodermic injection of morphia should be given without delay. The nurse should manage to give as little disturbance to the patient as possible in the use of the bed-pan, in some cases life may depend upon such absolute rest that even this appendage must be dispensed with, napkins and other appliances being used for the time. Cold to the abdomen should be tried. The large rectum is too heavy. A napkin laid in two folds over the abdomen with small pieces of ice between answers all purposes.

In severe cases food by the mouth is to be almost stopped, but being sustained by minute doses of concentrated beef essence given at considerable intervals, with small pieces of ice between and the regular administration of small peptonised enemata of strong beef tea, to each of which a few minims of laudanum may be added. Food enemata are recommended, but they do more harm than good in some cases.

Chloride of Calcium (15 grs. every hour for four doses) has now replaced the host of so-called hæmostatic drugs as Ergot, Matico, vegetable astringents, Lead, Copper, Iron, Turpentine &c. It certainly does save life after all these have been tried in vain. Mathieu gives the Chloride of Calcium (1 drachm in a quart of water at the temperature of 114° F. per rectum, while the drug is also given by the mouth.

Suprarenal Extract or its active principle, Adrenalin, by the mouth or hypodermically has recently been highly recommended and excellent reports are forthcoming of its powerful hæmostatic

properties. Adrenalin has been given by Reichert hypodermically in doses of 0.005 grammic ($\frac{1}{400}$ grain). It has also a powerful effect in strengthening the heart.

Gelatin as a hæmostatic has been several times referred to in the preceding pages. If injected into the veins experiments prove that it has striking power in so altering the blood as to check hæmorrhages, and recently Lancereaux and others have shown that when used hypodermically the solution has the same power, it certainly has some hæmostatic power when applied locally, and several observers maintain that it also acts efficiently when given by the mouth.

Musser injected hypodermically 10 c.cm. of a 10 per cent. solution in the hæmorrhage of typhoid fever with success. The dose should correspond to 15-45 grs. pure gelatin when given hypodermically in 6 per cent. saline solution. The solution must be absolutely sterile, and since it is practically harmless if carefully prepared it may be given in amounts up to $\frac{1}{2}$ oz. by a large hypodermic syringe every few hours or oftener.

Sailer, who gives an exhaustive description of the technique of the employment of the remedy in the *Therapeutic Gazette* of August, 1901, recommends its administration by the mouth in the form of a firm jelly sweetened and flavoured with lemon. This would seem to be an unobjectionable agent in the treatment of the hæmorrhage occurring in typhoid fever.

Stimulants should be partly suspended, only enough being given of food and alcohol as will keep the patient alive till in the period of dead low water the open vessel has been sealed up by a coagulum.

PERITONITIS must be met by the most rigid rest and large doses of Opium; cold to the abdomen and the maintenance of life by small peptonised enemata, and a very few bits of ice sucked in the mouth. If good nutrient suppositories are at hand they would be indicated. There must be no movement of the patient's body made in administering the enemata. His faint chance for life depends upon starvation, rest, and opium. This latter is to be given by the rectum or hypodermically. Many cases are on record where laparotomy, suturing the bowel, and flushing out of the peritoneal cavity have saved life. Platt has collected 103 cases with 21 recoveries, and recent reports continue to show a progressive diminution in the mortality. Surgery is far more likely to be successful in those cases of perforation coming on during convalescence, but recent successes would lead one to hope that soon the opening of the abdomen in all cases will be considered imperative.

PERITONITIS is to be treated upon the same lines—rest and opium. Cold applications are as a rule not so well borne as warm ones, and the best plan is spongio-piline soaked in hot water and kept in place by a light bandage. Poultices are generally, unless very skillfully made, too weighty.

BED SORES should be prevented by careful nursing. When they have occurred they must be treated by absolute cleanliness and the applications detailed under Bed Sores, page 73.

TYMPANITIS is best met by the exhibition of intestinal antiseptics. Turpentine in the form of capsule may be given, to minus every two hours, and a large enema, followed by a small one containing Asafetida, may be tried; the long tube is generally useless. MacLagan urges laparotomy and opening of the cæcum in those cases where the paralysis of the bowel and the presence of putrid sloughs convert the cæcum into a cess-pool.

RETENTION OF URINE can only be met by catheterisation, and the soft rubber catheter should always be employed. Where the urine is ammoniacal the bladder may be washed out by some antiseptic solution, or, better still, by adding 20 grs. of Boracic Acid to the day's supply of milk.

Miscarriage, Pneumonia, Albuminuria, and other complications are to be treated upon general principles, keeping in mind the indications for the various drugs mentioned under the heading of the complication.

During convalescence the greatest care is to be exercised regarding diet and locomotion. Every time solid or animal food is administered, for the first few days the range of temperature is to be carefully watched and a return to liquid food insisted upon if any substantial rise occurs. It is almost a universal mistake to prolong the administration of alcoholic stimulants too far into the convalescent period. The patient should not be permitted to leave his bed for at least 12 or 14 days after the temperature has fallen to the normal. Some physicians begin drugging with tonics, but these are seldom necessary. The writer feels that the following summary of the treatment of typhoid fever is well worth repeating; it is from an able address delivered by the late Dr. Bristowe:—

"In conclusion, gentlemen, let me state briefly the treatment to which I should like to be subjected if ever, unfortunately, I should become affected with enteric fever. I should like to be placed in a cool, well-ventilated room and covered lightly with bed-clothes, and to have a skilful and attentive nurse to look after me, to be fed solely with cold milk, unless vomiting should demand the addition to the milk of medicine calculated to allay vomiting. If diarrhoea became troublesome, or ever there was much pain or tenderness in the cæcal rings and in the bowels, I should like to be treated, not with laxatives, but with Opium, given either by the mouth or by the rectum. If constipation were present I should, excepting in the first week, like to have enemata only employed for its relief. In the event of intestinal hæmorrhage coming on, I should like to have ice to suck or ice-cold fluids to drink, cold compresses to the belly, and cold injections into the bowels; and though I am sceptical as to their efficacy, I should still choose to have astringents, and more especially Lead, given to me at short

intervals. If perforation should take place, let me have large and repeated doses of Opium. Stimulants I should prefer to do without early in the disease; later, however, and during convalescence, I should like to have them in moderation. As to the cold baths, I would rather not have them, but I would nevertheless leave it to my physician to exercise his discretion in the matter. I would leave it also for him to decide, according to circumstances, whether alcohol should be administered to me in large quantities. I would prefer not to be treated at a temperance hospital."

The preventive treatment of typhoid fever is a subject of enormous importance, and the influence of water and milk as carriers of the disease has been thoroughly demonstrated in many epidemics. Sanitary precautions in these matters and in the disposal of excreta, urine, sputa, &c., need not be dwelt upon.

Professor Allbutt has recently drawn attention to the spread of typhoid fever from the pollution of water by the urine of patients who had been convalescent for considerable periods from the disease, and Dr Thomas Houston, a most reliable observer, has reported the discovery of the typhoid bacillus in the urine of a patient suffering from cystitis. "The parasite must have been there for at least two or three years.

The injection of attenuated cultures of the typhoid bacillus as a preventive has been tried upon a large scale in the late Boer war; complete returns are not yet available, but from the lists already published the fact appears that inoculation very considerably diminishes the risk of catching the disease. In the siege of Ladysmith 14 per cent. of the uninoculated suffered, whilst only 2 per cent. of those inoculated were attacked by the disease, the case mortality being the same in both. The Indian statistics (Wright and Leishman) proved that inoculation reduced the proportion of affected soldiers from 25 to under 1 per cent., with a diminution in the death rate from 34 to 2 per cent. of those affected. Wright's recent Egyptian figures testify to a nineteen-fold reduction in the number of attacks, and to a three-fold reduction in the number of deaths.

TYPHUS FEVER.

The previous article upon the treatment of typhoid fever, in most of its details, applies to the treatment of typhus.

The chief omission required will be the management of the complications, which of course do not happen in typhus.

The selection of the sick room is detailed upon page 966, and the general directions regarding nursing, &c. are identical. This fever being highly contagious, the sick room must be most completely cut off from the rest of the house, and it is held that, owing to the volatile nature of the contagion, the room should be at the top of the house, or that no occupied rooms should be situated above it. In hospitals, as well as

in private houses, at least 3,000 cubic feet of air space is necessary.

Where there are many inmates in the house and where the air space is limited, the wisdom of treating a disease which spreads alarmingly in over-crowded situations is more than doubtful. In the case of schools and public institutions it should not be attempted, removal being considered essential.

It is almost as important as in typhoid fever to insist that the patient takes to bed immediately.

Food is to be the same as in the case of typhoid. Though there are not the same urgent necessities for a purely liquid regimen, owing to the absence of bowel ulceration, nevertheless the great advantages of a purely liquid dietary are so well recognized that every detail applying to typhoid fever in this respect can be here equally well. More beef tea and chicken or other soup can be given, as there is not the same danger of exciting diarrhea and it is a good plan to give milk and beef tea alternately in most cases where the patient takes to this method.

The question of alcohol as discussed under typhoid exactly applies here. The stimulants may, however, be commented on at an earlier date; and, speaking generally, the writer would say that, in his experience, there is more need of alcohol and more good to be expected from it in typhus than in typhoid fever. All old patients require it, but children very seldom do. The dose may reach 15 or even 20 ozs. whiskey in the twenty-four hours. The key-note to the use of alcohol, antipyretics, and baths lies in this one consideration—that the siege, though a severe one, will be almost certain to last only fourteen days, and the entire effort and one thought of the physician should be to fight the disease with the view of exterminating it, but to try by a purely expectant method to keep the patient alive till the expiration of that time. In some cases within sight of the goal life may be sustained upon stimulants when all else fails, but it must ever be remembered that life can be sustained upon stimulants for a very short time only, and alcohol as a routine agent must not be recommended.

Life may sometimes be saved by the judicious administration of Strychnine, when the heart is failing and does not respond to alcohol. As a rule, Digitalis is not to be relied upon.

The remarks about antipyretics apply equally to typhus and typhoid, with this difference, that, as we know how long the attack is to last, we can the better judge of the necessity for their administration.

Chemical antipyretics have not yet been proved to be of any real service, and the value of the cold or tepid bath is not yet established in the same way as in typhoid as a routine element in the treatment. The occasional use of the bath is beyond doubt of the greatest value when the temperature is high, but the writer thinks that its routine employment should not be commenced in

the temperature reaches at least 103°. Quinine may be used at the same time in some cases with advantage. The bath is the only reliable agent for hyperpyrexia in this as in other diseases. Cold sponging of the body and limbs should be made a matter of routine in all cases. The writer can speak of its comforts and its benefits from personal experience. As in typhoid, the internal administration of 15 or 20 minim doses of the Dilute Muratic Acid is the best simple routine procedure.

Delirium, headache, and sleeplessness may be met by ice to the head and counter-irritation to the nape of the neck. Some authorities blister the forehead or scalp in such cases. Musk (10 grain doses) with Oil of Cajuput (5 mins.) the writer has used with advantage when the nervous symptoms and prostration have been alarming. As an hypnotic, Chloral may be used in conjunction with large doses of Bromides; but at a late stage it should not be given on account of the weakened heart which is an element of typhus. Opium cannot be borne when the headache and delirium are marked, unless when given, as advised by Graves, along with moderate doses of Tartar Emetic.

The newer hypnotics may be tried with advantage. Cold sponging is admissible in all cases.

Coma must be promptly met by cold affusion if the temperature is high or by rectal injections of strong coffee, or by coffee by the mouth, if the stupor is not complete. Murchison laid stress upon the necessity of counter-irritation over the loins, with cupping glasses or sinapisms covered by mackintosh, in deep stupor, and he blistered the scalp by strong Ammonia in some cases. The writer would recommend the hot blanket bath under such circumstances, and the general treatment for acute uræmia mentioned upon page 84, if albumin is found in the urine and the temperature be not high.

Owing to the blurred mental condition of the patient his bladder must be carefully watched, and the soft rubber catheter passed as often as needed. Food must be, for the same reason, regularly forced upon him, and his position changed from time to time as he lies in bed to avoid hypostatic congestion.

Pneumonia must be met by free stimulation, counter-irritation, and the internal administration of Ammonia in full doses. If the typhoid state be present ammonia should not be given: then full doses of Turpentine, with a little Ether and Cajuput, are admissible. The Glycerin of Borax should be applied to the tongue and mouth frequently, and bits of ice and small but frequent draughts of iced water may be given all through the disease.

The patient often fails to ask for water, but the nurse should see that he gets it as regularly as his nourishment and stimulants. Free elimination is of vital moment, and water is too often withheld.

After the fall in the temperature rapid convalescence begins.

The stimulants should be lessened after the first 24 or 36 hours and in three or four days almost stopped. By that time the appetite has improved, and semi-solids, as farinaceous foods like chicken, oyster, &c., may be given inside a week from the time the fever heat. The following tonic is useful in this stage —

R. Quinina Sulph. ʒss.
 Acid. Nit-Hyd Dil. ʒiv
 Tr. Calumbæ
 Tr. Quassia ana ʒj
 Inf. Auranti ad ʒviij. misc.

Fiat mistura. Capiat cochleare magnum ex cyatho vinario aquæ ante cibos ter in die.

ULCER.

Under Anus, page 52, the treatment of ulcer of the anus & rectum will be found.

Under Gastric Ulcer, page 311, the treatment of ulceration of the stomach is detailed.

Rodent Ulcer, page 861, will give the remedial procedures for that affection.

The treatment of ulcers of the mouth is described under Stomatitis and Tongue, on pages 889, 897, and 956.

Lupoid, scrofulous, and syphilitic ulcerations are detailed under their appropriate headings.

Perforating ulcer of the foot is dealt with upon page 678.

The treatment of the various ulcers almost necessitates a description of each, so many varieties have been named, and the same words are used in different senses by different writers. The writer will describe the treatment of the *healthy, healing, or omphalocutaneous* sore, which, in the vast majority of cases, is found upon the lower half or two-thirds of the leg in adults. At different stages of its progress, such a sore may vary considerably in character, and by changes in the patient's health, or by injuries or by prolonged exercise, &c., the healing ulcer may become a "inflamed," "irritable," "weak," "sloughing," "indolent," or "eczematous" sore.

The treatment of the *healthy or simple cutaneous* sore or ulcer is for the most part easy. Rest and the application of almost any moist dressing will speedily assist healing.

Rest is the main element in treatment, but it is not easily obtained in most cases. Few people will take to bed for the sake of healing a small sore which is giving little trouble. Almost all the advantages of a prolonged rest in bed may be obtained through the application of an even elastic pressure. The introduction of the Martin's India-rubber bandage has wrought a

revolution in the treatment of ulcers, and though its application is not essential for the healing of a simple ulcer, nevertheless in most cases it will greatly expedite it. Should the ulcer become chronic, its use is excellent. There is a serious objection to the rubber bandage which maintains in many cases, and it is the liability of the retained secretion of the skin setting up a general eczematous condition of the entire limb. This may become a serious matter. Hence the writer uses a modification of the bandage for most cases of ulcer of the legs, which he treats in the following routine manner:—

A double ply of lint is neatly cut out with scissors to the shape and size of the ulcerated surface. A piece of oiled silk, half an inch larger every way, also is prepared. The lint is soaked in ordinary Carbolie Lotion (1 in 40), laid upon the sore, and covered with the oiled silk. Where there is any tendency to eczema, the skin around the edges of the ulcer, where in contact with the oiled silk, may be smeared over with a little Lard, Vaseline, or any stiff emollient ointment. This prevents irritation by the retained secretion under the oiled silk. Over the lint and oiled silk a woven rubber bandage, about $3\frac{1}{2}$ inches wide, such a bandage as is used for Esmarch's bloodless operation, is applied evenly from the toes up. This bandage is manufactured in the same way as the elastic spring-sides of ordinary boots, and it is known as "elastic webbing." It should be taken off when the patient retires to bed, and put on before he gets up in the morning, any ordinary bandage being used to keep the dressing in its place during the night.

Instead of the carbolie lotion, any of the following lotions may be used from time to time according to the appearance presented by the sore, viz.—Sterilised Water, Concentrated Boracic Acid Solution, Spirit Lotion (1 in 4), Chlorate of Potassium (4 grs. to 1 oz.), Chloride of Zinc (2 grs. to 1 oz.), Liquor Plumbi (15 minims to 1 oz.), Black Wash, Yellow Wash, Corrosive Sublimate ($\frac{1}{8}$ gr. to 1 oz.), Chloral Hydrate (3 grs. to 1 oz.), Acid Nitric. Dil. (5 minims to 1 oz.), Tincture of Benzoin, Hazeline, Iodine 1 gr. to 10 ozs.), Sulphate or Nitrate of Copper (1 gr. to 1 oz.), Nitrate of Silver (5 grs. to 1 oz.), Sulphate of Zinc (2 grs. to 1 oz.), &c. The hospital Red Lotion consists of 16 grs. Sulphate of Zinc, 2 drs. Compound Tincture of Lavender, and 8 ozs. Water.

Where any watery solution seems to irritate, an oily solution like Carbolie Oil (1 in 15), or almost any of the above-named substances made into an ointment with Lard, Spermaceti or Zinc Ointments, or any of the following B.P. Ointments: Boric Acid, Calomel, Resin, Salicylic, Creosote, Carbolie, Eucalyptus, Iodoform, Lead, or Oleate of Zinc may be employed.

When a greasy application is made, it is better, as a rule, not to cover it in with oiled silk, though the Carbolie Oil does admirably when so applied.

The dressing may be applied twice daily, and if a liquid

application has been used, a stream of tepid water should be passed over the face of the ulcer to wash away all secretion before the fresh lint is applied. When ointments or oils are used the ulcer should be lightly cleansed by gentle wiping with cotton. Some surgeons after the cleansing of the surface of the ulcer apply a piece of green protective oiled silk dipped in Boric Acid solution direct to the surface of the sore, and lay on a larger pad of lint soaked in the same solution upon the top of the silk to absorb the discharge as it oozes out at the margins.

Simple ulcers often heal rapidly by placing a piece of sheet-lead or thick lead foil over the dressing. The writer has seen excellent results from the lead being laid directly upon the sore without the intervention of any dressing.

Weak ulcers are those in which there are abundant flabby pale or watery-looking granulations. This condition may to a certain extent supervene upon the healing ulcer, but it more frequently exists from the first, and is a strong indication for Cod Liver Oil, and Iron pure air, and extra feeding. The local treatment may be summed up in the word stimulation. The best of all remedies is the Solid Stick of Nitrate of Silver pencilled over the cedematous granulations, followed by a dressing of dry lint under a suitable elastic bandage.

At a later stage the sore may be rubbed over every two or three days with a large crystal of Sulphate of Copper. The best dressing is the Diluted Nitric Acid Lotion, or a weak Solution of Sulphate of Copper, or of Nitrate of Silver, or Chlorate of Potassium.

To apply upon the sore a piece of lint which has been saturated in the Tinct. Benzoin Co., and cover over with lead-foil and a bandage, is an excellent method of dealing with this variety of ulcer.

The Unguentum Resine is a valuable dressing for this and the following form of ulcer:—

The typical *indolent* ulcer goes by many names, and an infinite variety of treatments has been recommended for it. Stimulation must here be severe, the application of the Solid Nitrate of Silver seldom succeeds except in very mild cases. When possible the patient should lie up, so as to get the treatment well started. The first step in treatment is to thoroughly cleanse the often foul greenish-coloured watery surface, and get rid of every trace of dead matter by Carbolic or Corrosive Sublimate in very weak solution. Poultices, so often recommended, are not to be applied, much more will be obtained by antiseptics under oiled silk, and very frequent and very thorough bathing.

The edges in all chronic cases are raised and callous, and of almost cartilaginous consistence, so that this type of sore is often called the *callous* ulcer. As long as these edges remain in this condition recovery or healing is not possible.

Before resorting to severe measures pressure may be tried, and sometimes even in most unpromising cases the skillful use of a

Martin's India-rubber bandage acts like a charm. It may be applied direct to the face of the ulcer without any intervening dressing. The patient should apply it himself every morning before leaving bed, and he soon gets to feel the requisite amount of tension which increases as he assumes the vertical position. The bandage is kept on all day and not removed until the patient is flat in bed. It is then washed in a basin of water containing a trace of some antiseptic. The ulcer is to be likewise carefully cleansed, and a thick pad of lint soaked in Spirit or Carbolic Lotion placed over it till morning under a plain calico or stocking-web bandage. The skin of the limb is generally found so macerated and tender that it will not be advisable to cover in the night lotion by oiled silk, though this may sometimes be done to advantage.

Sheet-lead, cut a little larger than the ulcer, may be laid over one or more plies of lint soaked in weak Corrosive or any other lotion, and placed upon the surface of the ulcer, the whole being covered by a pad of lint or gauze, and kept in position by elastic webbing or woven India-rubber bandage as just described. Excellent results follow this method where the pure rubber bandage cannot be tolerated.

Watson, of Boston, modifies this plan by laying a piece of protective over the face of the sore after thoroughly disinfecting it with a 1 in 4,000 Corrosive Sublimate Solution, over this he places a piece of sheet-lin, the whole covered by a dry Corrosive Sublimate gauze dressing, held in place by an evenly applied bandage from the toes to the knee. The lead-foil and woven rubber bandage are better. Where these plans fail after a good trial, during which the patient may be permitted to follow his avocation (this is the great value of the method), other measures may be tried.

Blistering of the ulcer and its margins is recommended, but this is a painful and often useless plan, and may possibly cause sloughing.

The best treatment at this stage is to take a sharp bistoury and make a series of alternately deep and shallow linear incisions through the thickened or callous margins, radiating outwards from the centre of the ulcer, like the spokes of a wheel from the nave. The deep incisions should penetrate the deep fascia, and extend for an inch or two beyond the margins of the ulcer. Bleeding is easily stopped by pressure. This method is more successful than paring down the edges of the sore. The writer thinks it was first practised in the Edinburgh School, and he has seen its great success in many cases in the hands of an old pupil of Syme.

Harbordt, apparently independently, has introduced a slight modification of this method which is thus described by Spaeth.

The entire ulcer is divided lengthwise by a deep incision, extending far into the healthy tissue. Cross incisions are then made through the callous tissue into the healthy at intervals of

about three-quarters of an inch. The incisions must go through not only the skin, but the underlying fascia: the wounds must gape widely. The bleeding, often profuse, must be stopped with tampons, and the whole wound, which it must be owned has rather a slaughter-house look, is done up with Iodoform dressings. When, after eight to fourteen days, the dressing is changed the difference in appearance is very marked. Healthy granulations are springing up in abundance from the gaping incisions and soon cover the whole surface reaching the level of the surrounding skin from which the growth of new epidermis is seen to advance rapidly.

Scraping of the ulcer may be tried before resorting to this procedure in some cases where the edges are not very thick and raised.

Strapping of the ulcer should be mentioned. It is, however, seldom needed now, as all that it can possibly do is better done by the elastic pressure of Martin's bandage.

Skin-grafting may be needed where the ulcer is extensive but it is useless to attempt the operation till the entire nature of the sore has been first altered by some of the above plans. Sponge-grafting has very often failed. The skin grafts should be very small. Though they may be numerous, they do best when planted inside the edges of the sore.

Thiersch's method of skin-grafting may be employed with benefit in many cases. The ulcer is sterilised as far as possible by the free application of pure Carbolic Acid for two or three days. The surface is then thoroughly scraped by a sharp curette, and the indurated margins removed by the knife. Hemorrhage is arrested by pressure, and one or two large grafts applied at once. If asepsis has been secured healing will be complete at the end of a week when the dressings are removed for the first time.

Unna's treatment of chronic ulcers of the leg is applicable to the simple, indolent, and varicose forms. The leg is washed with soap and water and covered over everywhere, except at the ulcerated spot, by a paste consisting of 1 part of pure Gelatin, 1 part of Oxide of Zinc, 4 parts of Glycerin, and 4 parts of water. Iodoform is then freely sprinkled over the ulcer, which is afterwards to be covered with any antiseptic gauze laid over a layer of cotton wool. Over all are applied two double-headed wet muslin bandages with their ends crossing in front. They should extend from the middle of the foot to the calf. Once or twice a week will be in the majority of cases sufficiently often for changing the dressings, but when the discharge is profuse this may be necessary every second or third day. Hillebrand, who has obtained excellent results from this method, claims for it that it draws the healthy skin towards the ulcerated margins and rapidly facilitates healing. [I have obtained surprising results by painting the ulcer and surrounding skin with Unna's Zinc Ichthyol Gelatin covering

the whole with lint, and leaving the dressing unchanged for several days.—A B M.]

Electricity may be used in various ways for the healing of very chronic ulcers. The most convenient and simple plan is that devised by Bird, and described upon page 74. He covers over the ulcerated spot with a disc of silver, attached to a plate of zinc by means of a wire. The zinc disc is placed over the neighbouring skin, from which it is separated by a layer of wash-leather soaked in vinegar.

Massage of the ulcer and of the surrounding tissues has been highly recommended and practised.

Papain has been used to cause disintegration of the thickened edges of very chronic ulcers, and several surgeons have tried to establish healing by inducing inflammation by means of Jequity infusion or a paste (1 in 4) of the powdered seeds, but, as a rule, the results have been unsatisfactory.

The writer has seen very decided benefits follow the fumigation of the ulcer by means of Calomel vapour. In *sypilitic* ulcers this appears to act sometimes like magic, but in nearly all forms and varieties of chronic ulcer its benefits are most striking. The patient lies in bed, and the Calomel is put into the receptacle in the apparatus used for giving a hot-air bath in Bright's Disease (this is briefly described upon page 85), and the Calomel vapour is conducted under the bed clothes by a narrow tin tube whose extremity is placed immediately opposite the ulcerated surface.

Where all plans fail, and the ulcerated surface has been permitted to involve a large area of the leg surface, amputation may be the only alternative to a bed-ridden existence.

In such cases Bell Keatley's operation is a distinct advance. He scrapes the ulcer thoroughly, removes the bones and soft tissues of the dorsum of the foot, and transfers to the site of the ulcer the whole of the sole of the foot, including muscles, plantar vessels, and nerves, and excluding loose tendons after removing a small portion of the lower end of the tibia. The result is a good stump, like a Syme, instead of an ordinary amputation at the knee. He also preserves the dorsal foot flap for ankle amputations in cases of *complete circular ulcer of the leg* by bending it round upon its neck and covering with it the ulcerated surface.

It must always be kept in mind that, though the local treatment of the indolent ulcer is most important, little advance can be made unless constitutional measures be closely attended to. This is true also as regards all forms of chronic sore. Healing may be impossible till good food in abundance, and tonics, pure air, and every means by which the nutrition of the body can be improved, have got a fair trial.

The *irritable* and the *inflamed* ulcer are often very difficult to deal with, and the measures already mentioned are contra-indicated till all pain and tenderness are removed, as stimulating lotions or

ointments, or the pressure of the rubber bandage, will only aggravate the patient's sufferings.

Absolute rest in the horizontal position is essential. Generally the administration of purgatives affords some relief, and the effect of half a minim of Croton Oil is often very striking; it appears to possess some specific action over the irritable ulcer.

Pil. Hydrarg. Subchlor. Co. is also useful, and it may be employed to keep up the effect of the Croton Oil, if given in doses of 5 grains every night at bed-time.

The writer has seen the pain and discomfort associated with the irritable ulcer yield rapidly to the following pill, which is a modification of Plummer's Pill:—

R. *Hydrargyri Subchloridi* gr. iss.
 Antimoni Sulphurati gr. ii.
 Resinæ Guaiaci gr. ii.
 Olei Crotonis m ʒ. misce.

Fiat pilula. Mille tales xxiv. Sumat unam omni nocte a mane ad tertiam vicem, deinde unam pro re nata.

Saline purgatives are to be preferred in the case of the inflamed ulcer where there is much pain, heat, redness, and swelling in its margins.

Constitutional remedies for the relief of pain may be indicated, but, as a rule, opium and other narcotics are not to be employed except to produce sleep at bed-time. A combination of Bromide of Sodium (30 grains) and Antipyrine (5 to 10 grains) may be given two or three times a day when the pain continues to disturb the patient.

Locally the irritable ulcer may be best treated by Cathartic Lotion (1 in 30) under oiled silk. When this fails, 2 per cent Cocaine Solution may be tried. If this latter does not give immediate relief it may be rejected, and a lotion of Chloro Hydrate (1 in 200) may get a trial. The old Lead and Opium Lotion under oiled silk may do well, but very often every sedative application appears only to aggravate the pain. Under these circumstances by far the best plan to pursue is to apply a strong solution of Cocaine (8 per cent.) for 15 minutes, after which the ulcer and its edges are to be well painted over with the strongest solution of Nitrate of Silver (60 or 80 grains to 1 oz.), or the Solid Stick may be used. After cauterisation, soothing evaporating lotions may be used for a few days, when the ulcer may be regarded as a simple sore, and treated by the agents already enumerated.

The inflamed ulcer is best dealt with by cold evaporating lotions and the elevation of the limb, after Saline purgatives have been used to establish a free discharge from the bowels. A few small

incisions with a sharp-pointed tenotomy knife will give better results than leeching, and in very severe cases one poultice may be applied to encourage the bleeding from the incisions, but poulticing, as a rule, is bad practice in the treatment of ulcers.

Sloughing ulcers call for supporting and stimulating constitutional treatment. They occur in intemperate and often in syphilitic and diabetic subjects, and the agents indicated in phagedæna may be demanded. Thus Opium, Alcohol, tonics, concentrated beef essence and jellies must be given freely.

Local treatment will depend upon the peculiarities of the case. Thus, if the sloughing process seems to be spreading, a free application of the strong Nitric Acid may be demanded, but if the process appears to be at a standstill, measures which hasten the separation of the slough will be indicated. Weak antiseptic lotions, as Corrosive Sublimate (1 in 5,000), Permanganate of Potassium (1 in 1,000), Nitric Acid (1 in 3,000), or Carbolic Acid (1 in 60), may be used to irrigate the sore and its immediate vicinity.

After constitutional measures have been used, and the patient's general condition improved, the ordinary applications suitable for a simple healing ulcer may be employed.

Varicose ulcers are those occurring upon limbs, the seat of a varicose or enlarged condition of the veins. The term is a bad one, as any form of ulcer may be and generally is classed as varicose when occurring under these circumstances. The appearance of the sore will give indications for the employment of some of the previously-mentioned plans of treatment. As a rule, however, little progress will be made unless the condition of the veins is specially attended to. Rest is essential, and, if the ulcer be not irritable, this may be accomplished without sending the patient to bed if a good rubber bandage can be worn during the day-time. Laplace urges operative treatment for the cure of the varicose veins to hasten healing and to prevent recurrence of the ulcer.

Many therapeutists still believe that Hazeline or Hamamelis exerts some specific action upon the coats of veins, and hence a lotion consisting of equal parts of hazeline and water is a favourite application to the so-called varicose ulcer. The writer uses the Martin's bandage, applied directly to the limb, during the day, and the following lotion at night under oiled silk. —

R. *Spiritus Vin Rectif.* ℥ii.
 Hazelin ℥iv.
 Aquæ Rosæ ℥ii. misc.

Fiat lotio. *Signa*—"To be applied to the sore spot upon limb and covered over with oiled silk."

Eczematous ulcers are generally a variety of the last-mentioned as they are nearly always associated with varicose veins. Their treatment is often very troublesome, and will depend upon the stage of the eczema present. If the case is of long standing and the eczema be scaly, the rubber bandage may be tried cautiously. If the patient can tolerate it without uneasiness, it may be found to remedy the three abnormal conditions at the same time—viz. the varicose veins, the ulcer, and the eczema. Unfortunately, however, it will be found sometimes to increase the eczema by preventing the escape of the secretions of the skin and of the ulcer. Two courses will then be open—either to send the patient to bed and treat the eczema and ulcer, or to resort to the woven rubber bandage described upon page 989. Under this application any suitable eczema remedy may be applied to the limb while the patient is permitted to pursue his ordinary avocation. Boric Acid Ointment is a good routine remedy.

As a rule, in the *eczematous* ulcer, moist applications under oiled silk should be avoided. Under the woven rubber bandage powders like Oxide of Zinc, Starch, Bismuth, &c., can be applied if there be much secretion; or stimulating ointments like *Le Basilicon*, or the valuable combination given in the recipe upon page 260, may be spread upon lint and laid in contact with the sore.

The rubber bandage should be always worn after the healing of the ulcer, or the veins may afterwards be tied and cut, so as to radically remedy the varicose condition.

George Stoker treats all forms of ulcer by immersing the affected part in a box in which it is kept surrounded by Oxygen gas. There is a special home in London where the treatment is carried out under his direction.

URÆMIA—See Bright's Disease (Page 84).

URETHRAL CARUNCLE.

The only satisfactory treatment is the removal of the growth this can be effected after the application of cocaine, by snipping it off with sharp scissors and applying the cautery to its bleeding base. A simpler plan is to directly apply Paquelin's cautery to the growth and permit it to slough off afterwards. Where the tumour is of any magnitude it should be excised by the knife or scissors taking a clean sweep of the underlying tissue, avoiding, however the narrowing of the urethral orifice.

URETHRAL FEVER.

Where rigors supervene after the passage of an instrument down the urethra, the patient should be put to bed and have warm water bottles applied to the extremities, and a hot drink administered. Where there is no suppression of urine or suspicion of kidney disease, hot whiskey punch often checks the shivering. Quinine

may be administered, and 20 or 30 minims of Tincture of Opium may be advantageously combined with it. The sweating may safely be encouraged.

Where suppression of urine is present the case generally assumes a serious aspect, and the writer has seen excellent results from a very hot blanket bath (see page 83), or the ordinary hot bath, hot poultices to the loins, dry cupping, or a copious warm or hot water enema may be administered, the general treatment of acute Bright's disease being indicated, including Phlorescine, in severe cases. Those who regard catheter or urethral fever as always of renal origin caution against the administration of opium or alcohol in any form, and rely upon smart Salines, warm fomentations to the kidneys, or hot baths.

The urine should be rendered aseptic if after the attack it is found to be abnormal, and this may be accomplished by the internal administration of Boracic Acid Salol Creosote, Oil of Eucalyptus, or Urotropine, or by washing out the bladder with warm concentrated boracic acid solution, especially if the rigors have supervened upon lithotomy, or any bladder operation which minimises the danger of passing an instrument again through the urethra.

Preventive treatment is of the greatest importance, and the surgeon will be wise who makes it a rule never to pass an instrument down the urethra for the first time in a patient unless he be previously sent to bed, or put to bed immediately afterwards and kept absolutely quiet and warm for the day.

A hot bath before or immediately after the operation may prevent the attack, and at the commencement of treatment for stricture, which is the usual cause of this complication, the previous hot bath serves a double purpose.

Where there is any reason to anticipate rigors, an opiate should be given one or two hours previously, and immediately before operating a few drops of weak cocaine solution should be injected down the urethra. Quinine, which is often valuable after the rigor, generally is useless in preventing it. This the writer often demonstrated in a patient who had intermittent fever in his youth, and who had alarming rigors after every time a bougie was passed through his stricture. Soft instruments when possible should be used, and the most rigid attention to asepsis is imperative. The best lubricant is the thick Glycerin of Borax.

URETHRAL RUPTURE.

The treatment of laceration of the urethra should be, when possible prompt. If seen immediately after the injury, a large soft catheter should if possible be passed into the bladder and retained there. Where this cannot be accomplished the surgeon should freely cut down upon the point of a grooved staff or director in the perineum, and after careful dissection an instrument

may be passed along the urethra through the proximal end of the rupture into the bladder.

When the bladder is reached, the catheter should have been attached so as to drain off the urine continually as it trickles from the bladder from the ureters; the wounded urethra can then be sutured over the retained catheter. Often, however, it will be found that the bladder end of the rupture escapes detection and the only resource open to the surgeon is to do supra-pubic cystotomy, and guide an instrument from above through the neck of the bladder into the urethra. Should there be any difficulty in passing an instrument along the torn urethra, the surgeon may empty the bladder by supra-pubic aspiration for 4 or 5 days after which the patient will probably be able to pass urine without danger of extravasation. A flexible bougie can then be coaxed into the bladder and dilatation commenced.

Ultimately a suitable plastic operation may be indicated when the patient survives the cystotomy and the sloughing caused by extravasated urine. Sapiejko has obtained success by trim planting grafts taken from the mucous membrane lining the lower lip, with the view of restoring the destroyed portions of the urethra, grafts as large as one inch by one quarter of an inch were sutured to the ends of the divided urethra.

Ruptured urethra is invariably followed by stricture, for which systematic dilatation will be required, and the patient should be taught to pass a full-sized bougie at regular intervals of 3-4 weeks.

URINARY FISTULA.

As this condition is generally a sequel to stricture of the urethra, abscess of the prostate gland, or extravasation of urine from traumatic causes, the treatment of the primary condition will call for surgical interference.

The affection varies widely in different cases owing to the route taken by the original urinary abscess. Thus only one sinus above the scrotum or perineum may exist, whilst as many as fifty openings have been seen studded over the same region and extending into the rectum and above the groins. The treatment will therefore, necessarily vary considerably.

Given a simple fistula, opening at the one extremity into the urethra, and at the other into the perineal region, it will be found in the great majority of cases, to be secondary to a stricture of long standing. Such a fistulous opening, even when of long duration, will as a rule, heal as soon as the urethral stricture is properly dilated. Under the heading of Stricture of the Urethra upon page 400, the various plans of dealing with the primary affection have been detailed and need not be here repeated. As a rule, it will be wise to begin with solid metal bougies, passed every two or three days, till the fullest size which the urethra is capable of taking is reached.

In many instances, however, it will be found that the anterior end of the stricture will only admit the finest instruments after much difficulty, and under these circumstances it will be necessary to begin with filiform bougies or soft catheters passed down the urethra, and coaxed into the bladder. When the bladder has been entered the instrument should be tied in, and after 24 or 48 hours a larger one may be made to take its place.

When about No. 6 English size is reached, the dilatation may be further carried out by the interrupted method of passing the larger graduated solid metal sounds, which will enable the patient to go about and pursue his ordinary avocation.

In some cases the fistula will be found to still remain open after full dilatation has been accomplished, and after waiting a reasonable time the surgeon must resort to other methods. The cause of failure in such cases always depends upon a small quantity of urine finding its way into the fistula each time the patient makes water. This keeps the tract green, and prevents healing. As a rule, the plan of injecting irritants or caustics along the fistulous tract in such cases is bad practice, though still advised by some surgeons. The practice of tying in a large catheter in the bladder is still worse. The best procedure by far is to teach the patient to pass a large-sized soft instrument, and caution him not to attempt to make water without its aid upon any occasion. Even before having a motion from the bowels he should immediately pass his catheter, and draw off every drop of urine. In this way all trickling of urine along the fistulous tract is completely prevented, and in a short time complete closure results. The use of the catheter may then be discontinued.

This method will also be found to be efficacious in those cases of urinary fistula caused by prostatic abscesses.

When two, three, or four openings lead direct from the perineum into the urethra without much induration or any diverticula, success may follow the above line of treatment, or internal urethrotomy. When, however, the tracts of the fistulae are in connection with regions riddled by small abscesses, the perineum may be opened by a free external incision made over a Senné's staff for perineal section, and all indurated tissue freely removed, the fistulous tracts scraped by a sharp curette, and packed with strips of Iodoform gauze.

Hurry Fenwick advocates free excision of every track or burrow right up to the urethra, and suture of the raw surfaces thus produced. Of course this is only attempted after free dilatation of the urethral stricture. He speaks very highly of the results of this method of treatment.

In those cases where from the first the stricture is impassable by any instrument introduced along the urethra, the treatment so successful in simple cases cannot, of course, be pursued. There is nothing left in such cases for the surgeon but to cut down upon the seat of stricture by perineal section, and by the Boutonniere

operation the urethra may be divided upon a Wheelhouse's straight grooved steel staff. In some cases Cock's operation may be performed, and the urethra divided behind the stricture in its membranous portion.

Wheelhouse's operation is the best for most cases, and is described along with the other methods under Stricture of the Urethra upon page 905.

The after treatment may require the continuous use of the soft rubber catheter passed into the bladder upon every occasion by the patient when urine is to be voided. This must be perseveringly adhered to till after the openings have entirely closed up.

In penile strictures with fistulae, Nélaton's or Clark's urethro-plastic operation may be resorted to, or the transplanting method referred to in the previous article may be employed.

The internal use of Boracic Acid in fair doses is of great value in correcting the condition of the urine, and it is needless to say that the closest attention must be paid to diet and general hygiene.

URINE, RETENTION OF.—See Retention of Urine (Page 835).

URTICARIA.—See Erythema (Page 294).

UTERUS, Diseases of.

The treatment of the different diseased conditions of the womb has already been detailed under their several headings. Thus for the agents indicated in dealing with inflammation of the lining membrane and body of the organ, the reader is referred to the brief article upon Endometritis, pages 273-277. The management of cancer of the womb will be found under Cancer of the Uterus, upon pages 123-126.

Hæmorrhage from the uterus is referred to under Menorrhagia and Metrorrhagia, pages 573-577. Post-Partum Hæmorrhage and the remedial agents used in its prevention and treatment will be found upon pages 362-366.

Ulceration of the cervix or os is generally found associated with granular degeneration, and yields, for the most part, readily to the treatment mentioned under Leucorrhœa, which is so constantly associated with it. Where these measures fail, however, as they do in some cases, the eroded surface should be touched by some strong caustic through the speculum by means of a Playfair probe. Almost every caustic has been used for this purpose. The writer advocates as a routine agent Iodized Phenol (1 part of Iodine dissolved in 4 parts of Carbolic Acid). The following are efficient applications—Nitrate of Silver in solid stick, Nitric Acid pure Carbolic Acid Chloride of Zinc, Solution of Nitrate of Mercury or of Perchloride of Iron. Tampons of cotton wool

saturated in Glycerin, or, as the writer recommends, in the Glycerin of Borax, or in the Glycerin of Tannic Acid or of Alum, may be used with great advantage; if 10 per cent. of Ichthyol be added to Glycerin an ideal tampon for ulcer, cervical catarrh, or cervical endometritis will be obtained.

UTERINE DISPLACEMENTS.

The treatment of these ailments has been a source of controversy almost as fertile as has been their pathology. The physician who believes that the displacement is the primary cause of the symptoms which are often present contents himself with the various mechanical contrivances invented to keep the uterus in its normal position.

Upon the other hand, those who regard the displacement itself as secondary to some previous mischief content themselves by seeking out the primary cause of the departure from the normal, and treating it. There are others, however, who, whilst fully recognising that some abnormal condition of the uterus always underlies the displacement, believe that after this has been remedied to the fullest extent the organ may require to be kept in its proper position by an accurately-fitting pessary.

The writer believes that the best results in treatment will follow the use of measures directed under a proper appreciation of this last-mentioned view of the case. The subject is, however, one which can only be very briefly referred to in the narrow limits of the present volume. The treatment of *prolapse* of the uterus has been fully dealt with already upon page 791 to 795.

Retroflexion of the uterus is the most common of the abnormal positions of the organ demanding treatment, though it may often exist without producing any inconvenience or symptoms; it is generally associated with retroversion.

The primary mischief should be carefully searched for; some enlargement of the uterus, the result of chronic inflammation, which has led to hypertrophy and softening of the uterine walls, may be detected.

Atthill's view may be broadly accepted—viz., that the healthy uterus will not bend.

The enlargement may be simply the result of subinvolution after profuse menstruation or parturition, and the heavy organ may assume its normal position when it becomes reduced in weight. It may be the result of a tumour growing in the interior of the organ or embedded in its walls.

It will, therefore, be obvious that these causes should, when possible, be remedied if they still remain. Thus pain, heat, and tenderness must be met by the agents detailed under Endometritis, upon page 273, if the uterus cannot be replaced in its normal position without increase of pain and discomfort.

Rest in bed, hot douches, and the Glycerin tampon soon remove local tenderness, after which an effort should be made to

replace the uterus. This is best accomplished by inserting the left index finger into the vagina, and by conjoined manipulation the right hand from without anteverts the uterus by pressing the fingers down behind its posterior wall. The operation is perfected by withdrawing the left index finger from the posterior fornix, the vagina and pressing the cervix from the anterior fornix back into its normal position towards the hollow of the sacrum. Should this plan fail the organ may be replaced by passing a sound through the os, taking care to use only very gentle force, but the method is not without danger, and is inferior to bimanual replacement. As a rule, it will be found that it speedily resumes its abnormal position again. The best plan, therefore, will be to insert a Glycerin or 10 per cent. Ichthyol in Glycerin tampon twice a week, and keep the uterus in position with it for some weeks, after which time it may be found to retain its normal place as the enlargement and inflammatory action subside. After the insertion of the tampon close to the os in the cul-de-sac, a plug of lamb's wool, rolled hard and turned sidewise so that the ends will rest in the obturator foramina, should be inserted as recommended by Baldy, who combines with these measures intra-uterine applications of Tincture of Iodine. After this treatment, should the uterus tend to fall back into its abnormal position a vulcanite Hodge's pessary should be inserted, the upper convex end of the instrument being lodged well behind the cervix in the posterior fornix. Speedy relief follows the replacement of the organ and the introduction of the pessary, which may be worn for ten or twelve weeks at a time if it keeps in position and causes no pain or discomfort. Its presence need not interfere with the constant employment of the vaginal douche. After three to six months it may be removed, and the position of the uterus carefully examined after the lapse of a few days. If the retroflexion is found to occur upon the withdrawal of the support, it must be again inserted and worn till the uterus keeps the normal position after its removal.

Innumerable modifications of the above-mentioned pessary have been introduced, some of which may occasionally be indicated under exceptional circumstances. Thus Greenhalgh's spring instrument and Albert Smith's modification may be selected. Thomas's retroflexion pessary should be used where there is much prolapse of the ovaries with great relaxation of the pelvic floor. Schultze's sleigh pessary may be used where there is marked cystocele or rectocele.

Dudley insists upon the truth of the general proposition that if the cervix be normally placed, the body of the uterus will, in the absence of complications, take care of itself. This proposition is true in the case of prolapse, hence often the same pessaries prove useful in both retroversion, retroflexion, and prolapse, since the first step in the genesis of the retro-malpositions is prolapse.

Vulcanite is, as a rule, to be preferred to gutta-percha or rubber

covered metallic pessaries. Various flexible and stiff stem pessaries have been advocated in the treatment of retroflexion, but their use had better be confined to the hands of specialists. It is, moreover, hardly necessary to say that no attempt should be made to restore the uterus to its normal position if there are reasons for believing that the organ is bound down by adhesions in its retroflexed position.

Retroversion, which generally exists to some extent in most cases of retroflexion, is occasionally met with alone. The treatment will be conducted upon the same lines—viz., the remedying of all abnormal conditions, as metritis, subinvolution, tumours, congestion, &c., and the use of a Hodge's pessary to give support to the replaced organ as just mentioned.

Where pregnancy complicates the case, the retroverted organ must be carefully replaced, and the catheter used twice a day where symptoms of retention supervene.

Where pessaries cannot be tolerated, or where, owing to adhesions affecting the uterus, tubes, ovaries, &c., surgical procedures must be undertaken; of these the numbers are many, but Alexander's practice meets most difficulties. Where adhesions are present he opens Douglas's pouch, passes in his finger and breaks down all adhesions till the uterus is easily pushed forward into the position of anteversion. He then shortens the round ligaments and packs the vagina with gauze, having removed any pelvic lesion through the vaginal opening.

Anteflexion of the uterus. This displacement is to be treated upon the principles already mentioned as applicable to all uterine flexions or versions. The inflammatory, congested, hypertrophied, or subinvolved organ must be restored to a natural condition, as far as this is possible, by suitable agents, as dilatation, curettage, rest, Glycerin tampons, and hot vaginal douches. Ergot internally, and agents employed with the view of subduing pelvic inflammation may be necessary.

Puncture, leeching, or division of the cervix, and the regular introduction of the uterine sound have been advocated, and successfully practised. Pessaries, as a rule, fail. The writer has a few times succeeded with Graily Hewitt's anteversion pessary, and he has satisfied himself that this instrument, when it does give relief, does so by steadying the uterus as a whole, or by its presence exciting some reflex action which assists in improving the tone of the pelvic floor. He has seen excellent results with this cradle pessary when inserted upside down, both in anteflexion and retroflexion.

When inserted in this inverted way it steadies the uterus and is scarcely capable of being displaced. It is, however, most difficult to introduce and to withdraw.

Many authorities highly recommend the intra-uterine stem pessary of rubber, or the galvanic stem or glass stem pessary, and where the rubber or gutta-percha instrument of Greenhalgh can

be comfortably tolerated it may do good. The writer believes, however, that the only cases where it probably will do good are the mild cases, which will get well without any appliance whatever.

Forcible dilatation will be necessary in most cases where the pessary fails. This is best carried out by means of Goodell's or Ellinger's dilator. Sims' posterior division of the cervix has no given way to Dudley's method which consists of forcible dilatation, curettage, posterior division of the cervix, and folding of the cut surfaces upon themselves by means of sutures in such a way as to enlarge the calibre of the uterine canal, and at the same time straighten the uterus.

Anteversion, which is generally a direct result of inflammation of the uterus or its lining membrane, or of pelvic peritonitis or of pelvic cellulitis, may be best treated by agents directed against these lesions. (See under the heading of each.)

When the cause has been fairly dealt with and all pain and tenderness removed, the cradle pessary just mentioned may be inserted with its convexity looking upwards, as originally intended. Sometimes a Hodge seems to meet all the requirements of the case. Thomas's anteversion pessary may succeed, but, as a rule, stem pessaries should not be thought of on account of their danger.

Inversion of the uterus is a very serious displacement. Occurring immediately after delivery, if observed at the time, its reduction may be effected without much difficulty. The placenta should be at once removed and the organ returned to its normal position by inserting the right hand into the vagina and pushing up the uterus against the left hand, applied outside the abdominal wall.

In cases where the displacement has been overlooked for any time, the process of reduction may be very difficult, tedious, or impossible. The pressure by the hand may have a fair trial under chloroform before resorting to other methods; and if the uterus cannot be returned to its normal condition, reposition or reduction may be then tried by the use of White's reducing appliance, which consists of a disc fastened to a spiral spring by means of a curved iron rod. The disc or cup is carried up into the vagina and placed in contact with the fundus, against which it is held firmly by the hand in the vagina. The spiral coil of wire is held against the breast of the operator, on the same level as the uterus, and steady even pressure is thus kept up upon the fundus which gradually is repositioned with the assistance of the operator's free hand applied to the abdominal wall above the pubes.

Other plans are practised, one of which is to dilate the urethra so as to admit a finger into the bladder, whilst another finger is introduced into the rectum, and pressure applied in this way upon the anterior and posterior margins of the depressed rim, whilst counter-pressure is applied to the fundus from without by the balls of the operator's thumbs.

Emmet's plan is to push the fundus up till it can be enclosed by

the os, which latter is then closed by sutures after paring of its margins.

The *gradual* method of reposition may be tried. It consists in introducing a rubber bag into the vagina, in contact with the fundus. Water is then slowly forced into the bag by hydrostatic pressure, and by this slow, even pressure the fundus is gradually returned.

The same principle may be carried out by using the hollow cup of Thomas, which is applied to the fundus, as in the case of White's repositior, but the pressure is made by elastic cords attached to the stem of the cup and to an abdominal bandage.

When all these measures fail, amputation of the inverted uterus with the knife or galvano-cautery may be resorted to; vaginal amputation is condemned.

Lateral versions and flexions and the various mal-locations of the uterus depend in the main upon inflammatory causes, and yield to the appropriate treatment for the local inflammation, followed up by local massage. As a rule pessaries are useless or harmful.

UTERINE FIBROIDS.

The treatment of the fibroid polypi of the uterus has been detailed under Polypi, on page 782, and the treatment of the hæmorrhage (the main symptom of uterine tumour) is mentioned under Menorrhagia. The tumour often, however, causes no symptoms, and is only discovered perhaps by accident, and is best let alone in such cases. When pain, pressure symptoms, and hæmorrhage call for relief, three methods of treatment are available. These are—Ergot or Hydrastis, Electricity, and surgical procedures. Full doses of ergot by the mouth, or by parenchymatous injection, or by suppository, have in many instances caused considerable diminution in the bulk of the tumour, and corresponding improvement in the symptoms. The following pill may be prescribed, and the dose gradually increased.—

℞. *Ergotin.* (*Bonjean*) gr. ii.
 Extract. Nuc. Vom. gr. ½.
 Quinine Sulph. gr. ij. *misce.*

Fiat pilula. Mitte xxiv. tales. Sumat i. bis in die.

Where a steady use of the above fails to give relief electricity may be tried as described under Menorrhagia. Many writers condemn electricity entirely, and the method is passing into disuse. Baldy states that the percentage of cures about represents the percentage of errors in diagnosis. Apostoli confesses that "it does not constitute a radical treatment of fibromata, and it is only exceptionally that one sees them disappear under its influence.

It will continue purely a symptomatic treatment, and as such will prove sufficient in the great majority of cases to carry women suffering from fibroids safely through to the menopause, and rescue them from operative surgical interference." The death rate has, however, been high, and the percentage of cures very small. Intra-uterine tamponade (see page 576) may be necessary to check hæmorrhage, and sometimes intra-uterine styptics may be pressed into the service.

Surgical procedures should be considered when the hæmorrhage, pressure symptoms, and pain become constant and severe. Palliative methods, such as removal of the appendages and ligation of the uterine arteries and ligaments with the view of starving the growth, and curettage with the view of stopping hæmorrhage, may be tried, but, as a rule, the results are unsatisfactory. Where the growth is sub-mucous it can generally be removed per vaginam after dilating the os. Vaginal hysterectomy is indicated in small interstitial fibroids. Where the pedicle is small the ceraseur may be used as for polypi. Vaginal enucleation and morcellation is now employed frequently for large tumours, especially when there is no reason to expect suppuration of the tubes. The different methods of performing hysterectomy with their numerous modifications and details are beyond the scope of the present work.

VAGINISMUS.

In very mild cases the application of emollients or local sedatives may have a trial before resorting to operative interference. As a rule, however, little is to be expected from this plan if the symptoms are severe. The following may be tried:—

- R. *Cocainæ Purificatæ* gr. xxx.
 Morphinæ Purificatæ gr. xv.
 Unguenti Conu ʒi. misc.

Fiat unguentum. Signa—"A little to be smeared over the painful spots with the finger."

Or the following medicated pessary may be tried —

- R. *Cocainæ Purificatæ* gr. i.
 Iodoformi gr. x.
 Extracti Belladonnæ gr. iss.
 Olei Theobromatis q. s.

Ut fiat suppositorium.

Where speedy relief does not follow the use of these local applications, a careful inspection of the vaginal orifice should be made, and any abrasions, irritable caruncles, fissures, or ulcers

should be incised or removed by knife or scissors after the application of a strong Cocaine solution, or under the influence of chloroform. The remains of the hymen should be carefully cut away by the scissors.

No operative interference, however, is of any avail unless the vaginal orifice be dilated to its widest extent. This may be done by inserting the thumbs and forcibly rupturing the muscular fibres by strong traction, or a bivalve speculum may be introduced and the blades gradually opened. Afterwards a large vaginal bougie or a glass dilator should be introduced and worn by the patient for several days and afterwards for a few hours daily.

In severe cases Sims' operation must be performed. This is carried out under chloroform by making an incision two inches long upon each side of the vaginal orifice, down through the mucous membrane, and dividing the superficial part of the muscular fibres. The incision should extend from above the level of the ostium to the raphe of the perineum. The vaginal orifice is to be dilated forcibly by the fingers, and if there be much hæmorrhage, the canal should be firmly plugged.

The glass dilator must be worn during healing at least once a day. In a very severe case under the care of the writer, Atthill removed entirely, with marked success, a narrow strip of mucous membrane on each side of the vaginal orifice.

Froelich makes two long incisions upon the posterior vaginal wall, and then dilates widely, when the incisions become transformed into two lozenge-shaped wounds with their transverse diameter the longer. The upper and lower edges of each wound are sutured together, making a line of suture running at right angles to the original cut, and considerably enlarging the vaginal calibre.

In the majority of cases a cure follows after parturition.

VARICELLA or CHICKEN-POX

In the vast majority of cases requires no treatment. In rare cases where the affection is severe, rest in bed and the administration of a mild diuretic, with occasional sponging of the skin with a weak Alkaline solution, meet all requirements.

In the rare gangrenous variety antiseptic lotions or ointments will be indicated, and complications like pleurisy and secondary abscesses must be treated as they arise. A generous diet and skilled nursing are requisite, as this type is only met with in ill-nourished and unhealthy children.

VARICOCELE.

Palliative measures always should have a fair trial in this condition before operative procedures are thought of unless the case be very severe or of long standing, or where the subject of it is exposed to severe physical exertion, or where he wishes to enter

into some department of the public service. Indeed, many cases cease to give trouble after a few years even without treatment.

Change of occupation has led to the disappearance of the varicose condition of the scrotal veins in several instances under the writer's notice, where the patient relinquished an occupation compelling him to stand the entire day, for one entailing a considerable amount of sitting, with some open-air exercise. In all cases the scrotum requires the support of a good suspensory bandage; constant bathing and sponging of the skin does good. The regular and persistent use of a cold douche night and morning, or oftener in hot weather, is of great service. It can be very easily applied by means of a piece of India-rubber tubing which can be attached to the cold water-tap in the bath, and in this way a stream of water can be directed on the scrotum. It should be kept running till the part becomes almost numb. The writer has satisfied himself that great benefit may be obtained by kneading the scrotum between the finger and thumb several times a day, so as to excite contraction of the muscular elements. This is especially valuable in those cases where the scrotum is very lax and toneless. Lotions are of little use, as they must be covered it with oiled silk, when they soon act as poultices. The following may be sponged over the scrotum every morning before the patient begins to dress —

R. *Hædini* *℥iii*
 Spiritus Vini Rectif. *℥iiss.*
 Aqua Destillata *℥ivss. misc.*

Fiat lotio.

Constipation must be prevented, and sexual excitement and excesses guarded against. Electricity may have a trial, a weak continuous current passed through the moistened scrotal integument morning and night, combined with massage, greatly assists in improving the tone of the part. The wearing of a truss with the intention of compressing the spermatic veins in the inguinal canal is to be condemned. It may greatly aggravate the condition.

Internal agents as Ergot, Hamamelis, and other drugs supposed to act upon the blood vessels are useless, but there is no doubt that any good tonic which improves the general tone will assist the varicocele to disappear. Quinine, Iron, and Strychnine in combination, as in Easton's Syrup, may have a fair trial.

Where these agents fail in improving matters, operative measures should be considered, especially if there are any signs of wasting of the testicle on the affected side.

All the old operative plans have now been abandoned in favour of the open method, which is carried out as follows — The scrotum and groin having been carefully sterilised, a 2 inch incision is made, having its centre opposite the pubic crest; the cord and

dilated veins are freely exposed and drawn into the wound. The dilated veins are then isolated, care being taken not to injure the cord or its vessels. Two strong catgut ligatures are applied to the diseased mass of veins, about an inch apart, and the intervening portion excised; the ends of the ligatures which have been left long are tied together, so as to raise the testicle, and the wound closed by a continuous suture, which prevents infolding of its edges, which is so liable to occur in the scrotum, the wound will not require to be dressed for four to five days, and the patient will be up at the end of a week. Where the condition is very severe, and the scrotum pendulous, Brault advises the removal of an oval piece of the sutured tissue with the enlarged veins.

VARICOSE VEINS

Should be treated upon the principles already detailed under Varicose Ulcer, on page 995. Support to the dilated vessels by means of a properly-applied pure rubber bandage affords by far the best treatment for this condition. The bandage should be applied from the toes to the upper limit of the varix before the patient assumes the vertical position in the morning, and it should not be removed till he lies down in bed at night. Where the skin gets tender under its use, a perforated rubber bandage may be employed, but the elastic webbing described upon page 989 meets every requirement. These appliances are vastly superior to the old-fashioned elastic stocking which should never be recommended unless when the patient refuses to take the trouble of employing a rubber bandage. The writer has obtained good results by the application of the elastic webbing or a pure rubber bandage over an ordinary silk or cotton stocking.

Prolonged standing, the use of garters, chronic constipation, and anæmia or plethora should be guarded against, and everything calculated to improve the general health and diminish venous engorgement must be attended to.

Where these measures fail the veins must be excised or ligatured. The best results are obtained by ligaturing the vein in several places, and dividing it between the ligatures.

Trendelenburg ligatures the *internal* saphenous vein in all cases. He makes an incision, exposing the vein at the juncture of the upper and middle third of the thigh, and divides it between two ligatures, fixing the limb for ten days in cotton wool and a firm bandage. This method is specially useful for those cases in which the varicosity is general over the veins of the leg. Such cases, however, are not generally suitable for operation.

VARIOLA.

The treatment of small-pox differs in no way from that of the other eruptive fevers. The principles of treatment as applied to the management of Measles (pages 556-561), of Typhoid Fever

(pages 965-969), and of Typhus (pages 985-988), maintain also in the treatment of this affection, and need not be again enumerated in detail. They have been also enumerated under Scarlatina.

The sanitary surroundings of the patient demand the most careful attention, not only on account of the highly infectious nature of the disease, but also because of the extensive suppuration. Hence the most rigid isolation and the necessity for thorough ventilation. The details referring to the choice and arrangement of the sick-room and the patient's bed should receive special care. It is advisable to keep the temperature of the sick-room between 55° F. and 60°.

In severe cases, as in *Confluent Small-pox*, the pain in the back may be relieved by small doses of Antipyrine, administered, not with the view of producing a fall in the temperature, but with the intention of obtaining the analgesic action of the drug. For this purpose the dose should not exceed 5 grains, nor need the remedy be pushed for more than 24 or 36 hours. Sir J. W. Moore advises for this purpose dry cupping and the use of the India-rubber hot-water bag.

For the general condition there is no special treatment. At present we do not know of any agent possessing specific action over the disease. Antiseptic drugs have been extensively employed with the view of destroying the organism causing the fever, but it does not yet appear that any marked results have been obtained. Sanson's plan of administering the Sulphate of Sodium in 20 or 30 grain doses, or the Sulphocarbolsates in similar quantities, can do no harm; and though they have generally failed in making any very decided impression upon the constitutional symptoms, they may possibly sometimes turn the scale in the struggle against the microbe. Yeo has forcibly shown that slight modifications in the environment of the parasite may materially modify its activity. Thymol, Eucalyptus, Carbolic Acid, Corrosive Sublimate, and Salicylic Acid have been extensively employed, and of the latter drug Baudon has reported successes.

Sir J. W. Moore, as the result of his extensive experience, states that in Quinine in 5 grain doses and in Tincture of Perchloride of Iron in 20 to 30 minim doses we possess the two most valuable antiseptics known so far as small-pox is concerned. Bianchi carries out the antiseptic treatment to the fullest extent, with apparently excellent results (no deaths in 96 cases). He renders the surface of the patient, his bedding, room, and all his surroundings as aseptic as possible.

Various antiseptic solutions have been recommended for sponging over the body. The writer would strongly recommendunction of the patient's skin with the Oil of Eucalyptus mixed with Olive Oil (1 in 5) from the very commencement of the disease.

The Mineral Acids internally, as in the other eruptive fevers, give

very good results, and in mild cases or modified small pox should constitute the only treatment.

Alcoholic stimulants are to be administered when necessary, the indications being identical with those already fully discussed upon pages 976 to 979. When free suppuration occurs, stimulants in conjunction with large amounts of concentrated nourishment must be given at short intervals, and the cold or tepid bath may be resorted to, as in the treatment of typhoid fever, often with advantage.

In the hæmorrhagic variety of the disease, large doses of Iron and Quinine must be administered by the mouth, whilst Ergotin is given by deep parenchymatous injection, and Turpentine by the bowel. Chloride of Calcium, in doses of 10 grains every two or three hours, may be tried. Suprarenal Extract (5 grains), or Adrenalin $\frac{1}{16}$ gr. hypodermically, or Gelatin Solution subcutaneously, may be tried.

The following is the formula used by Sir J. W. Moore at the Cork Street Hospital. —

R. *Extracti Ergotæ Liq.* ʒij.
 Olei Terebinthinæ ʒij.
 Spiritus Ætheris Nil. ʒij
 Spiritus Rectificati ʒj.
 Ovi Vitellum
 Aquæ Mentur Pip. ul ʒviij. *misce.*

Fiat mistura. Signa—"One-eighth part every third, fourth or sixth hour, as required."

The treatment of such complications as headache, delirium, insomnia, and diarrhœa is already detailed under Typhoid Fever.

Macdombie recommends Morphia hypodermically, in a $\frac{1}{2}$ grain dose, repeated in an hour or two if the delirium continue.

The local treatment of the eruption is of the utmost importance, especially upon the face, and there is practically no end to the list of methods recommended with the view of preventing pitting.

Stokes laid down three indications for treatment which are accepted by Moore and other authorities. He insisted upon the exclusion of air, the keeping of the parts in a permanently moist state, so as to prevent the hardening of the scabs, and the lessening of the local irritation.

He carried out these indications by the application of poultices—a plan which has, however, steadily diminished in favour since the introduction of the antiseptic methods of treatment.

The objections to the linseed poultice are overcome by sprinkling a little Iodoform over its surface.

Any unirritating antiseptic solution may be applied upon lint covered by oiled silk. Thus Boracic Acid is a favourite application, either covered by oiled silk or used as an evaporating lotion.

Weak Corrosive Sublimate Solution (3 grains in 10 ozs.) has been used by Skoda and Hebra. Carbolic Lotion (1 in 80), Carbolic Oil (1 in 8), and Carbolic Pastes made with Chalk and Oil are highly recommended.

As a rule, thick oily preparations are more valuable than watery solutions. The writer recommends the following:—

R. *Liniment Calcis* ℥iiss.
 Olei Eucalypti ℥iv.
 Calamina Preparata 3j. misce.

Fial applicatio. *Signa*—"To be applied with a large camel's hair brush to the skin of the face every two or three hours."

Tincture of Iodine has been extensively used by brushing over the papules till the free suppuration stage has occurred.

Mercurial Ointment, diluted with 5 to 15 parts of Lard, has been tried and reported upon favourably. It is not without serious danger. A very innocent plan is to smear over the face with Olive Oil, and then to apply a powder consisting of equal parts of Subnitrate of Bismuth and prepared Chalk, but many authorities condemn all powdery applications during this stage when crusts are forming.

The plan of rigidly excluding daylight from the sick-room has some advocates, but it is manifestly objectionable, and by no means certain in its effects. Ultra-violet rays have some influence upon the skin, and it has been recommended to only admit red light through red glass window-panes or red curtains. Turkey-red window blinds would answer every purpose and keep the sick-room cheerful.

Traumaticine, Collodion, Gold Leaf, cauterisation of the vesicles by solid Nitrate of Silver, or their evacuation by means of a fine needle, and many other plans formerly in vogue are not to be recommended.

Moore covers the face by a light mask of lint soaked in a mixture of Iced water and Glycerin (8 to 1), and covers over the mask with oiled silk. Richardière covers the head and face with a helmet made of bandages soaked in solution of Sublimate (1 gr in 5 oz. water), which is kept on all through the disease, the muslin being wetted several times a day with the solution.

MacCumbie covers the face with a mask of lint having eyes and mouth apertures, and this he lines with a thin layer of linseed poultice smeared over with Iodoform Vaseline, this should be

changed every two hours. For the eyes constant cleansing and vaseline to the margin of the eyelids are necessary, and when corneal ulcers appear they should be dressed with Hyd. Ox. Flav. Ointment (1 gr. to each dr.), to which Atropine (2 gr. to each dr.) is added.

Sprays of any of the above substances may be employed. A weak Carbolic spray has many advocates, but it is difficult to see how it answers better than the lotion of the same substance.

Some authorities treat the entire cutaneous surface of the body by immersion in various medicated baths for long periods. A plan is immersion in a tepid or warm bath containing 150 grs. Sublimite for 15 minutes twice a day.

Borax and Glycerin (1 in 6) is the best application for the mouth and throat; and for laryngeal troubles the spray of Carbolic Acid, mentioned upon page 709, answers all purposes. The proportion of Cocaine may be increased in some cases.

Many cases of mild, modified small-pox require no treatment but rest in bed, a milk diet, a rigid isolation, with the occasional use of warm or tepid baths, and inunction with Eucalyptus Oil.

Attempts to utilize serumtherapy in the treatment of small-pox have proved unsatisfactory.

VERTIGO—See *Tinnitus* (Page 952), and *Ear Diseases* (Page 252).

VOMITING.

The treatment of this symptom is detailed under the various headings of the different diseased conditions which produce it. (See under *Dyspepsia*, *Cancer of Stomach*, *Gastralgia*, *Gastric Ulcer*, *Gastritis*, *Meningitis*, *Bright's Disease*, *Intestinal Obstruction*, *Sea-Sickness*, *Diarrhoea*, &c., &c.)

VOMITING OF PREGNANCY—See under *Pregnancy* (Pages 783 to 787)

VULVITIS.

After the free use of the sitz bath, in which a small quantity of Bicarbonate of Soda is dissolved, a weak Carbolic lotion (1 in 40) should be freely employed. A lotion of Lead and Opium often gives relief—*Liquor Plumbi Fort.* 1, *Tr. Opii* 1, *Water* 38. These lotions applied on lint should be placed between the folds of the vulva and repeated often. After the subsidence of swelling and discharge ointments may be used with advantage. (See the different formulæ under *Pruritus*.)

For vulvo-vaginitis of gonorrhoeal origin the best treatment consists in cleansing in a permanganate sitz bath and after drying the suppurating surface with cotton wool, a strong solution of Nitrate of Silver (1 in 12) should be painted over it, after which the vagina and vulva should be packed with Sublimite Gauze frequently renewed.

WARTS or VERRUCA.

The best treatment for these growths is to apply with a piece of match-wood the strongest Glacial Acetic Acid once a day. When there is a very extensive layer of epithelium, the wart should be shaved by a razor or a sharp scalpel before applying the acid, and when this is carefully done and any bleeding controlled by pressure, one application of the acid may be sufficient. Failure results through want of attention to this detail, the horny epithelium shielding the vascular tissue from the action of the acid. After the dried crust falls off or is removed the acid should be applied till entire destruction is accomplished. Saturated solution of Caustic Potash or the liquefied drug may be applied. It is more speedy and certain than the acid. A less painful application is that of Salicylic Acid in saturated solution in Collodion. (See page 176.)

Fowler's Solution of Arsenic applied daily with a fine camel's hair brush is a reliable wart destroyer, but the writer has found that it produces such pain after a time that often its use must be stopped. A minute quantity of arsenic made into a paste with water and applied to the wart causes its certain destruction. It is stated upon good authority that Fowler's Solution internally will check the growth of warts, the same may be said of Magnesia.

Resorcin, Butyr of Antimony Nitrate of Silver, Chromic Acid Mercuric Nitrate, Nitric Acid, Corrosive Sublimata, and nearly every known caustic has been recommended, but the Glacial Acetic Acid answers every requirement, even in the most unpromising cases. (See also Condylomata, page 158.)

The warts upon the face of aged people should be removed by a light touch of the electro-cautery, or preferably by incision with a sharp scalpel or scissors. The application of caustics may set up an irritation which sometimes causes the growth to take on malignant action.

WENS—See Sebaceous Cysts (Page 876.)

WHITLOW or PARONYCHIA.

Whether cutaneous, phlegmonous, periosteal, arthritic, or the result of osteomyelitis or tendo-vaginitis, should be strictly regarded as an abscess, and treated accordingly, as pointed out by Senn.

Measures should be directed to cutting short the suppurative process. Occasionally elevation of the part and the prolonged application of cold antiseptic solutions or ice succeed in producing the abortion of the disease. Where these fail to give relief and the suppurative process is manifestly progressive, aseptic poultices should be applied as hot as the patient can tolerate.

Ordinary poultices of linseed meal, if used, should be smeared over with Carbohc Acid, Boracic Acid, or other antiseptic. By keeping the finger immersed in very hot sterilized water relief is

often obtained, and the progress of matter towards the skin hastened. In all the varieties of paronychia, a deep and free incision under antiseptic precautions is the only valuable method of treatment. The finger may be completely frozen by the local use of a spray of Ether or of Ethyl Chloride, or anaesthesia may be induced by hypodermic injections of a few minims of a 4 per cent. solution of Eucaine or of Cocaine, after which an incision down to the bone with a stout sharp scalpel may be made without injuring or dividing the extreme finger tip.

The wound is to be treated upon ordinary surgical principles by antiseptic lotions and free drainage. Amputation is very seldom called for, the gentle removal of the necrosed bone often being followed by its reproduction within the periosteum, providing the incision has not been delayed too long, or provided the knife has been carried sufficiently deep and free.

In paronychia tendinosa or thecal abscess the pus should be evacuated by a free, deep incision made under chloroform down to the sheath, in the middle of the finger, and prolonged towards the palm if necessary. Where the inflammatory action or suppuration has involved the common sheath it should be opened above the wrist, or higher up the forearm, and the cavity washed thoroughly out by antiseptics and efficient drainage established, the hand and forearm being secured to a suitable splint.

WORMS.—See Tape-Worm (Page 930), Thread-Worm (Page 940), and Ascaris (Page 59).

WOUNDS.

[The surgeon's ideal in the treatment of any wound, whether deliberately produced in the process of an operation or accidentally acquired, is to obtain *primary union*. A brief reference to the precautions taken by the modern surgeon in order to ensure this in the case of incisions made during an operation will serve as a basis for the treatment of wounds of all kinds. The surgeon aims at securing—

(1) Thoroughly aseptic condition (a) of the skin of the patient for a considerable distance round the wound. (b) of the hands of the operator, and all instruments, sponges, and dressings likely to come into contact with the wound.

(2) Complete arrest of hæmorrhage.

(3) Accurate co-aptation of the wound surfaces and edges.

(4) The application of dry sterile dressings—e.g., gauze, which will permit of evaporation and absorption of any moist exudation.

The skin of the patient and the hands of the operator are purified in the same way.

First.—The area to be operated on is shaved, if necessary, then thoroughly washed with soap and water, and well scrubbed with a nail brush. In this way all dirt and the superficial layers of epidermis are removed, carrying with them enormous numbers

of micro-organisms. *This washing and scrubbing is the most important part of the sterilising process, and cannot be too thoroughly carried out.*

Second—The surface is treated with turpentine or ether, which removes oily material secreted by the cutaneous glands.

Third—The excess of turpentine is removed by the use of alcohol.

Fourth—The whole area is washed with solution of Mercuric Chloride (1 in 1,000) or other antiseptic, and, if time permits, a pad of gauze saturated with Mercuric solution is applied over night.

The hands and forearms of the operator are treated on similar lines, special attention being paid to the nails and creases of the skin. Where an operation is prolonged the hands should be frequently rinsed to remove the secretion which is exuded from the glands of the skin, and which contains micro-organisms in abundance.

Instruments, ligatures, sutures, etc., are sterilised by boiling in water, or better, 1 per cent. solution of Carbonate of Soda, for 5-10 minutes.

The area of operation is surrounded by towels, sterilised by boiling or by steam. All wipes or gauze sponges which are brought into contact with the wound must be previously sterilised.

Dressings, which generally consist of dry gauze covered by some absorbent material such as Gangee tissue or wood wool, are sterilised in a Lautenschlager's steam steriliser, but where this is not available several layers of plain, boiled gauze may be applied over the wound. Specially prepared gauze ready for use may be had from most chemists. Dressings, as a general rule, are not removed till the end of a week, unless pain or rise of temperature suggest suppuration.

Drainage is not now so frequently employed as formerly when suppuration was so common, but drainage tubes are still necessary where much oozing is likely to occur. They should be previously boiled, and may be removed at the first dressing; gauze, rubber or glass may be selected according to circumstances. Strong antiseptics are steadily falling into disuse, and where it becomes necessary to wash the wounded surface, boiled water or hot saline solution is found to be equally efficient and less irritating.

While the above principles apply specially to *operation wounds*, where they can be carried out with absolute certainty, they are also applicable to *acquired wounds*, which as far as possible should be purified and dressed on the lines laid down. When, owing to the extent of the wound, pain, or other cause, this cannot be efficiently done, it is much better to administer an anæsthetic under which the work can be thoroughly completed. Much subsequent pain and scarring will in this way be averted. It must not be forgotten that for each subsequent dressing the same attention must be paid to the surgeon's hands and to everything brought into contact with the wound as at the initial dressing.

Should suppuration unfortunately supervene, the wound or portion of it must be freely opened and regular drainage provided for.

Superficial wounds on the face, ears, and elsewhere may be sealed with a mixture of equal parts of Tr. Benzoin. Co. and Collodion Flexile, which must be promptly removed should redness and swelling indicate the formation of pus.

Lacerated and contused wounds should be sterilised as thoroughly as possible, but it is generally some time after the receipt of the injury before the surgeon sees the case, and complete asepsis under such circumstances is scarcely to be expected, even when the wound is dressed under an anæsthetic. Such wounds should not be tightly closed, it being better at once to provide for drainage, a counter opening being made at the most dependent position if necessary. A few sutures to keep the edges in apposition is the most that should be attempted. Any undue tension is to be avoided, as it is certain to result in sloughing of the damaged tissues. Where the wound is at all severe, absolute rest should be secured by the application of a suitable splint. Where a large area of skin has been torn away, the granulating surface may subsequently be covered with grafts by Thiersch's method. When the loss of skin has been very extensive, amputation may be necessary.

Poisoned wounds are to be treated upon the same principles as already mentioned under Septicæmia. In order to effect the most complete destruction of the septic substance it may be necessary to enlarge the wound before attempting irrigation. A Perchlonide solution (1 in 500) may be then freely applied, or powerful caustics may be used under special circumstances, as in post-mortem wounds, or in bites of rabid animals. (See under Hydrophobia, page 430.)

Gunshot wounds must be treated on the same surgical principles as ordinary wounds.

The experience gained in South Africa and in the recent Spanish-American war has clearly shown that the modern Mauser or Lee-Netford rifle, discharging a small bullet at an enormous velocity, produces a practically aseptic wound, which tends to close itself, and thus become cut off from the external air. These wounds appear to have been associated with little laceration or destruction of tissues, and curiously enough, death from deep-seated hæmorrhage was a rare occurrence, though traumatic aneurism, especially of the arterio-venous type, was quite common. Experience proved that bullets, however deeply lodged, gave rise to little irritation. Attempts at probing or exploring the wound with the finger generally resulted in serious harm. The unanimous opinion of all the leading surgeons was that interference was always dangerous and generally useless.

In the first instance, therefore, such wounds should have the skin around carefully sterilised, and should be dressed without any attempt to remove the foreign body. The X Rays have proved

very valuable in locating bullets, &c., and have rendered the old and uncertain method of probing quite unnecessary.

Gnsshot wounds of the abdomen and thorax received great attention during the Boer war, and the mortality from these terribly fatal injuries was far below that of any previous war. Here again, however, active interference was soon abandoned, operation under such circumstances having a frightful mortality. Treves, MacCormac, and Thomson have all strongly urged the wisdom of expectant treatment.

Compound fractures in South Africa did remarkably well under conservative aseptic surgery, especially fracture of the femur which, previous to the Spanish-American war, was always regarded as necessitating amputation. Indeed, amputation, according to Sir William Thomson, was never carried out in South Africa except a limb had been hopelessly shattered by a shell or explosive bullet and this, he says, was a rare event.

The wounds produced by ordinary firearms in the hands of a civilian differ, of course, from those we have been discussing. They are distinctly more dangerous, as they are less likely to be aseptic, and they produce more laceration owing to the lesser velocity of the projectile. The same principles, however, govern their treatment:—

- (1) Arrest hæmorrhage.
- (2) Sterilise the surface of the wound and surrounding skin.
- (3) Make no immediate attempt to remove the foreign body unless this can be done without difficulty.
- (4) Avoid probing, but locate the projectile as soon as possible by means of the X Rays.
- (5) If causing irritation, it may be removed at the surgeon's convenience. = A.B.M.]

WRITER'S CRAMP.

The treatment of this affection will be that of the so-called craft palsies. In the early stages a long period of complete rest should be insisted upon, and if the symptoms are severe a change of occupation when possible is the wisest course. Where the symptoms come on past middle life, or in clerks who cannot change their occupation, Massage and Electricity afford the only hope. Massage must be gentle, and at the same time very thorough, all the muscles of the forearm and hand being attended to. Electricity is useless unless in the form of the *continuous* current, combined with rhythmical movements of the fatigued muscles, as advised by Poore.

These agents must not be used in the presence of pain or neuritis; this must be first overcome by rest and blistering. The typewriting machine with a key-board often meets all difficulties, and enables the victim of writer's cramp to continue his work till the above agents permit him to use the pen again. Medicines are useless. The writer has obtained excellent results by getting the

patient to practice left-hand writing or mirror writing, but especially by practising a bold round form of handwriting, which is chiefly produced by the action of the arm and shoulder muscles, as in black-board writing.

YELLOW FEVER.

Recent investigations show that this disease is transmitted to man by the bite of a mosquito—*C. fasciatus*—which serves as the intermediate host of the specific parasite. The preventive treatment will, therefore, as in the case of malaria, consist in the protection of the individual from the bites of the insect, and of such measures as will lead to the extermination of the carrier.

Absolute rest in the horizontal position in bed, with very free ventilation, is essential in the mildest cases, especially as very mild examples of the disease may become malignant at a later stage of their course.

The disease runs a definite course, and, in the absence of any known drug exercising a specific action, the object of the physician should be to keep the patient alive by careful nursing, judicious feeding, and by a rational treatment of the various complications or symptoms which by their presence may tend to cut life short.

Eliminatory treatment in many cases gives good results when combined with hygienic measures. Diuretics, diaphoretics, and mild purgatives may be used from the beginning, and, owing to the condition of the kidneys, these agents may be demanded. The best purgative is Castor Oil, and the best diaphoretic is the hot mustard foot-bath (followed by Spirit of Nitrous Ether, Aconite, and small doses of Pilocarpine), both of which should be resorted to at the earliest opportunity. Blood-letting, mercurialisation, and severe purging are always contra-indicated, though Sternberg publishes numerous successes by small doses of Corrosive Sublimate combined with an alkali. The mercurial is, however, in too small amount to produce constitutional symptoms. The following is his formula, very slightly modified—

R. *Sodii Bicarbonatis* gr vii.
 Hydrarg. Bichloridi gr. ʒss.
 Aque Destillatæ ℥ii, *misce.*

Fiat solutio. *Signa*—"To be taken *recd* every hour."

With this treatment he affirms that he has reduced the mortality from 30 to 6½ per cent., and he is satisfied that the alkali will give the best of all results. His object in using it is to render alkaline the highly acid urine. It prevents suppression of urine and hæmatemesis, the bichloride being added simply with the view of preventing fermentative changes in the stomach.

Mitchell reports highly of this method of treatment. He

increases the strength of the mixture, using the following proportions:—

R. *Sodii Bicarbonatis* gr. xiiss.
 Hydrarg. Bichloridi gr. ℥s.
 Aquæ Destillatæ ℥ii. misce.

Fiat solutio. *Signa*—"To be taken every hour."

This would represent, if given hourly, rather more than 1 gram of Corrosive Sublimate every 48 hours, and it is obvious that such treatment could not be safely continued for many days.

Hyperpyrexia, as in other fevers, must be met by the cold or tepid bath, and high temperature falling short of hyperpyrexia should be reduced by cold sponging of the surface of the body. Quinine, as a rule, is disappointing, unless malarial influences are also present, and most authorities have ceased to believe in its efficacy.

The gastric disturbance generally present calls for very active measures, and it is claimed for the Corrosive Sublimate and Soda treatment that, if commenced early, it tends to keep this symptom in abeyance. Blisters or sinapisms to the stomach region, or internally, with small doses of Bismuth or Prussic Acid, may be tried. Flint restricted the diet to milk and Lime Water. Stimulants are indicated in the majority of cases, and Champagne may be freely given. Life has often been saved by the rectal administration of Brandy and Whiskey. The injection of large quantities of normal Saline Solution may be indicated.

Stubbert, of Nicaragua, states that the sheet anchors are free purging, diuresis, and diaphoretics at the beginning, with large hypodermic doses of Quinine; afterwards mild catharsis and free diuresis. When the yellow vomiting begins he recommends emetics (full doses of Ipecacuanha), followed by hypodermics of Morphine; finally, cardiac stimulants are indicated. Suppression of urine must be promptly met by sinapisms or dry cupping over the loins. The last-mentioned authority advises ℥ss gr. Nitroglycerin. Copious draughts of Soda, Kali, or Seltzer Water are recommended by all authorities, and when these are rejected frequent rectal injections of 20 oz. water containing a tea-spoonful each of common salt and bicarbonate of soda should be administered, or the solution may be injected subcutaneously under the skin of the thighs or abdomen.

Where hemorrhage is a prominent symptom the old astringents Turpentine, Gallic Acid, Ergotin, Iron, &c., are still recommended, but it is probable that Chloride of Calcium will prove more valuable.

Attempts have recently been made to apply serumtherapy to the treatment of yellow fever, but the results have been most unsatisfactory; the serum has failed in the laboratory and at the bedside.

BRITISH (OFFICIAL) WEIGHTS & MEASURES

WITH THEIR

METRICAL EQUIVALENTS.

 In view of the early introduction of the metric system of weights and measures into the British Pharmacopœia, the following tables of equivalents may be found useful for reference.

WEIGHTS AND MEASURES

OF THE

BRITISH PHARMACOPŒIA.

MEASURES OF MASS.

1 Grain	gr.	
1 Ounce (Avoir.)	oz.	= 437.5 grains
1 Pound	lb.	= 16 ounces = 7000 "

MEASURES OF CAPACITY.

1 Minim	min.	
1 Fluid Drachm	fl. drm.	= 60 minims
1 Fluid Ounce	fl. oz.	= 8 fluid drachms
1 Pint	Q.	= 20 fluid ounces
1 Gallon	C.	= 8 pints

MEASURES OF LENGTH.

1 Inch	in.	
1 Foot	ft.	= 12 inches
1 Yard	yd.	= 36 inches

RELATION OF VOLUME TO MASS.

1 Minim	is the volume at 62° F. of	0.9114583 grain of water
1 Fluid Drachm	"	34.6875 grains "
1 Fluid Ounce	" 1 ounce or	437.5 " "
1 Pint	" 1.25 pounds or	875.0 " "
1 Gallon	" 10 pounds or	7000.0 " "
109.7143 minims* = the volume at 62° F. of 100 grains of water.		

* This is taken as 100 minims throughout the B.P.

WEIGHTS AND MEASURES OF THE METRIC SYSTEM

MEASURES OF MASS

1 Milligramme	= the thousandth part of 1 gramme or 0.001 gramme	
1 Centigramme	= the hundredth	0.01 "
1 Decigramme	= the tenth	0.1 "
1 Gramme	= weight of 1 millilitre of distilled water at 4° C. (39.2° F.)	1.0 "
1 Dekagramme	= ten grammes	10.0 "
1 Hectogramme	= one hundred grammes	100.0 "
1 Kilogramme	= one thousand grammes	1000.0 "

MEASURES OF CAPACITY.

1 Millilitre	= the volume at 4° C. of 1 gramme of water	
1 Centilitre	=	10 "
1 Decilitre	=	100 "
1 Litre	=	1000 " (1 kilog)

MEASURES OF LENGTH.

1 Millimetre	= the thousandth part of 1 metre or 0.001 metre	
1 Centimetre	= the hundredth	0.01 "
1 Decimetre	= the tenth	0.1 "
1 Metre	=	1.0 "

RELATION OF CUBIC MEASURES TO MEASURES OF CAPACITY.

1 Cubic Centimetre	= 0.99984 millilitre
1 Cubic Decimetre	= 0.99984 litre or 1000 cubic centimetres
1000.0 Cubic Centimetres	= 1 millilitre
1000.0 Cubic Decimetres	= 1 litre or 1000 millilitres

RELATION OF THE METRIC STANDARDS TO THE
IMPERIAL STANDARDS.

STANDARDS OF MASS.

1 Milligramme	=	0.015	grain nearly
1 Centigramme	=	0.154	grain nearly
1 Decigramme	=	1.543	grains nearly
1 Gramme	=	15.4323564	grains
1 Kilogramme	= 2 lbs 3 oz.		
	114.4564 grains	or 15432.3564	grains

WEIGHTS AND MEASURES.

1023

STANDARDS OF CAPACITY.

- 1 Cubic Centimetre = 16·9 minims nearly
1 Litre = 1·75980 pints or 1 pint 15 fl. oz. 1 fl. dr. 34 m. nearly

STANDARDS OF LENGTH.

- 1 Millimetre = 0·039370 inch
1 Centimetre = 0·39370 "
1 Decimetre = 3·9370 inches
1 Metre = 39·370113 " or 1 yard 3·37 inches nearly
-

RELATION OF THE IMPERIAL STANDARDS TO THE METRIC STANDARDS.

STANDARDS OF MASS.

- 1 Pound = 453·59243 grammes
1 Ounce = 28·34953 " or 28·35 grm. nearly
1 Grain = 0·064798918 gramme or 0·0648 " "

STANDARDS OF CAPACITY.

- 1 Gallon = 4·5459631 litres
1 Pint = 0·5682454 litre or 568·336 c.c.m. nearly
1 fl. Ounce = 0·0284123 " or 28·417 " "
1 fl. Drachm = 0·003552 " or 3·552 " "
1 Minim = 0·000059 " or 0·059 " "

STANDARDS OF LENGTH.

- 1 Yard = 0·914399 metre
1 Foot = 0·30480 metre = 30·48 centimetres
1 Inch = 0·02540 metre = 25·40 millimetres

Press Opinions

"The work now before us is a most complete dictionary of therapeutics, arranged alphabetically, and dealing with surgery and medicine as well as medicine. One of our numerous contributors at the Wd is, a high standard is to be expected and such a result comes fully up. Every subject which we have read is treated fully and attractively, and throughout the whole work there is a careful attention to perspective whereby each different subject has an account of space proportional to its relative size. The methods recommended are in every instance those of the most scientific men who, and where rival opinions are current the author states them clearly and refutes them from his own point of view. The whole work is written by universities and individuals, its literary style is excellent, and its success is certain." *Edinburgh Medical Journal*.

¹⁰ A work which is so comprehensive in its design necessarily demands much thoughtful consideration, not only from the writer but from the reader as well. The reviewer necessarily approaches his task with a sense of inherent co-easiness if the serious issue of attempting to contribute upon subjects covering such a wide range and ambitious to do justice is a work which must have cost the author considerable expenditure of time and labor.

It may at once be said that for W. I. is too very fine a vessel to be what might almost have been thought to be a superfluous task in supplying a book which is intended to serve as a guide to the practical treatment of a most essential thing that is capable of being created by drugs. The book is remarkable for free from pretensions or any need to pretend to clean type or good paper. It is also rendered more practical by the insertion of numerous formulae which the author has found valuable. — *The Lancet*.

"The book seems to be one of the best of its class." *Thornbury Gazette*

"The Professor of 'Materia Medica' and 'Therapeutica' in the Queen's College, Belfast, ad. has already written an excellent hand-book in Materia Medica which has been widely appreciated, now contributes for general everyday use a 'Dictionary of Treatment' to which the practitioner may turn when perplexed with the certainty of finding a short and rational and thoroughly practical article in almost every difficulty."

—British Medical Journal

'The Dictionary is in short the recorded experience of a practical and able therapist, who has carefully studied diseases at the bedside and in the operating room, and has earnestly endeavored to transfer the knowledge of his experience to his colleagues by his carefully selected upon the thoroughness with which he has realized his aim. His extensive knowledge of medicine and the therapeutic agents and the exceptional opportunities he has enjoyed for testing them clinically, combined with his able observation and untiring industry have led to the production of a book which will add to the knowledge and will prove of great practical service to large numbers of his professional brethren.' *Canadian Medical Journal.*

¹ It is the most complete and satisfactory work of its kind published. — *International Journal of Medical Sciences*

"This is a work which fills a void long felt in medical literature" - *Journal of Heredity*
Herbert H. Seward

"Professor Whittle's *Dictionary of Treatment* is intended to be a replacement in comparison to his well-known *Manual of Pharmacy, Materia Medica and Therapeutics*. The reason is the practical use of the book at every medical university and type of hospital, perhaps more as a practical information on new treatment than any other knowledge of a Medicine of Surgery. For that the book is almost new. It is a summary of treatment, coming next to the actual subject of the work, we find that a summary, we have already seen, is an easy one to do, but it is not easy to do, in a way, *Antiquité de la Médecine*. The *Dictionary of Treatment* is a very good example of the modern movement of industry in reading and gathering new knowledge from a wide range of the range of medicine, including the use of books and the use of the word 'book' in these days of the plan. Professor Whittle, in the use of the term 'book' and 'dictionary' of his knowledge the use of medicine. The *Dictionary*.

To all the members of musical societies to which we have referred, and to all persons who are and to be engaged in the cause, we warmly recommend Dr. Williams' "Treatise of Temperance." It is not only sound and well adapted to the times, but it is also a most valuable and useful work, and we are confident that the friends of the cause will find it a most useful and valuable work. We have nothing but admiration for Dr. Williams' industry and perseverance, for such a work as this must have cost him a great deal of time and labor, and we warmly congratulate him on the success of his undertaking. In the language of the "Treatise of Temperance,"

BY THE SAME AUTHOR.

EIGHTH EDITION (IN COURSE OF PREPARATION). 12 MO. BND. CLOTH, 75 CENTS, OR 62

A MANUAL OF PHARMACY, MATERIA MEDICA, AND THERAPEUTICS.

THE BOOK CONSISTS OF FIVE SECTIONS, ESPECIALLY ARRANGED FOR QUICK AND
EASY REFERENCE.

1. Practical Pharmacy: the Compounding and Dispensing of Prescriptions, Mixture and Pill Making, Blister and Plaster Spreading, Incompatible Recipes, &c. Illustrated by Woodcuts, Tables of the Galenical Preparations, &c.
2. Administration of Medicines, including Prescription-Writing and Autograph Recipes (Autographed), Latin Syntax, Vocabulary of Latin Contractions, parsed and translated
3. Materia Medica of all the Official Remedies. Arranged *alphabetically*.
4. Therapeutics of the same, with the Results of most recent Experiments, and Pharmacology and numerous Prescriptions.
5. The Materia Medica and Therapeutics of all the new and most recently introduced Non-Official Remedies.

Press Opinions.

"The scheme of the book is both novel and attractive. It would, indeed, have been difficult to find an author better qualified for the task of compiling a manual such as this than is Dr. Whittle. Intimately and practically acquainted with the details of pharmacy, well read in the subject of materia medica, and experienced in therapeutics, the author has succeeded in condensing within the limits of a handy volume the information which a student of medicine has usually to extract with great labor and loss of time from two or three of the larger manuals." *Dublin Journal of Medical Science*

"The work bears throughout the stamp of high merit. Taken as a whole, that is the best introduction to a difficult and complicated study that could be put into a student's hands. As Dr. Whittle points out, it brings under one cover information which, prior to its appearance, had to be sought for in two treatises at least. We may add what he has for some to say—that it also contains information which, hitherto, no manual has conveyed without anything approaching to equal accuracy or terseness. And in every respect, especially as concerns the practical details, he is the only available author." *Medical Notes*

"This is undoubtedly a most valuable contribution to the literature of pharmacy proper, embracing as it does every branch of materia medica. The chief part will be found to be quite a mine of wealth to the young practitioner. Dr. Whittle, evidently as a composed practical pharmacist, he never neglects an opportunity of impressing on his brethren the necessity of making themselves experts like himself." *Chronic Journal*

"The book supplies in a convenient form what one is usually obliged to search for in two or three larger works. It meets a want which has been much felt by students and will not only be very useful to them, but also to practitioners in general. The high standard attained by the first edition is not only maintained, but surpassed."—*Practitioner*.

"The task is undoubtedly a most difficult one, but the author has shown that in his hands at least it was not by any means an impossible one, for within 500 pages he has crowded such a mass of information as is seldom met with in a work of double the size. In the section on pharmacy he gives full, implicit, and most accurate directions as to the best methods of compounding and preparing the various articles in modern pharmacy. This is a particularly useful section in these days. The materia medica contains all that is necessary for the student to know, while the therapeutics is sufficiently expanded to meet the requirements of the student or practitioner. We cordially recommend it to our readers."—*Hospital Gazette*.

"The work contains a great deal of valuable information. It is evidently the result of much care and thought, combined with sound practical experience."—*British Medical Journal*.

"Dr. Whittle's book is well written, and will prove a useful student manual. It will be seen from the foregoing analytical notice that Dr. Whittle's work is evidently written to meet the wants of a very wide circle of readers, practitioners, medical students, and students of pharmacy alike may find within its pages that information which is requisite in the several branches. We can honestly say that so instructive and well-organized a manual has not often fallen into our hands, and the reviewing of it has been a pleasure, not a burden. It is one of the ablest text books with which it has been our good fortune to come in the course of our editorial labours. It is indeed such a work as will be expected from the pen of one who enjoys an established reputation as an able, earnest, and successful teacher. Professor Whittle has nothing to fear from honest criticism. The literary style of the volume is of no mean order of merit, and reflects credit upon the late Queen's University in Ireland, of which the author is a distinguished alumnus."—*British Journal of Medical Science*.

"The peculiar charm of Professor Whittle's book, and we believe the reason of its universal and enduring popularity, is that it adapts itself to the needs both of the student and of the practitioner, and to this we may add the further advantage of being evenly arranged whether for continuous study or for reference. It is, in full, a large observation. It is, moreover, one of the best treatises on the subject we have ever perused."—*Medical Press and Circular*.

"The work is one which could scarcely be too highly recommended to all. It is a model of condensation, and it would be difficult to conceive a better utilization of space, or the possibility of communicating more information within its limits."—*Therapeutic Gazette*.

"The production of this volume proves that the author possesses literary talent combined with patient research. The reader will be surprised at the lucidity and learning displayed, and how every detail is brought up to the latest discoveries in the different branches of medical literature."—*American Medical Bulletin*.

"This manual fully comes up to its already high reputation, and will be welcome to the student; it reflects, moreover, great credit on the teaching quality of its author. We predict for it a future increase of the great popularity which it has already attained."—*British Medical Journal*.

"Dr. Whittle's manual created such a favourable impression upon its first appearance that, in with much pleasure we received the notice of a new and enlarged edition. It is now well abreast of the times, the information given being of the most comprehensive character."—*Lancet*.

"Of the few good composite works the one before us is unquestionably the most successful example. In the course of seven years Professor Whittle's book has seen five editions, some of these numbers, as many as 40,000 copies, and it continues to present as complete and interesting a volume as we have in the English language. In reviewing the first edition of this work we noticed its excellent merits, and the practical Pharmacy of it, with the permission of the Author we quoted a short paper of general interest to dispensers. That in latter days has been taken up even since then, the number six *American Medical and Pharmaceutical Journal*, and is again taken up again in *Lancet*, showing that the general judgment of editors at least coincides with our own. *Chemist and Druggist*.
